Sir TRAVERS HUMPHREYS said that from his point of view the subject was divided into two parts: criminal and non-criminal abortion. By the latter he meant the steps which were taken by a qualified man to get rid of a condition in his patient which he was satisfied, on medical grounds alone, was dangerous to the patient's life or health. With that the law had no concern whatever. It might be that the patient asked a medical man to induce abortion because, for example, she feared social disgrace or for other non-medical reasons. These might form matters for advice to the patient so long as she was not in the condition of pregnancy, but in considering the induction of abortion he was not entitled to let anything weigh with him except the health of his patient—her medical welfare as distinct from her social or economic welfare. To say that a medical man would fortify his view by obtaining the best opinion he could, and that he would not interfere with the ordinary course of nature except for the gravest reasons, was only to say that he would do what a doctor would do in any case involving grave issues. Criminal abortion in this country was recognized as a very serious crime, and in the United States, France, and Belgium the law was similar to our own. In the Belgian penal code there was a provision that any person who caused abortion, even without desire to do so, by violence, or, as we should say, by ill treatment, was liable to extreme punishment. Those who studied French journals might be disposed to doubt whether in France the practice of abortion was regarded with quite as much distaste as it was by French law, but the mere fact, if it was a fact, that a certain number of people disregarded the law did not alter the law. It must be the law in every civilized country that criminal abortion was regarded in a very serious light, and the fact that abortion was legalized in Soviet Russia did not alter the case, because he was speaking of civilized countries. The induction of abortion, at all events by any other than the most highly qualified and skilful person, was fraught with the gravest possible danger to the woman. No doubt the increasing prevalence of the crime of abortion in this country was due to the widespread belief that abortion, at least in the early stages of pregnancy, was without risk; but he had heard Sir Bernard Spilsbury combat that idea in the witness-box, and say that there was no such thing as safe procurement, even in the early stage. He hoped medical men would impress that fact upon any of their patients who might be under misapprehensions on the subject.

General Discussion.

Dr. HALLIDAY SUTHERLAND referred to the effect of tuberculosis upon pregnancy. It had no constant influence. Women, even in advanced stages of the disease, had brought forth healthy children at full time. There were cases in which the onset of pregnancy was associated with increased severity of the disease, but others in which it was associated with amelioration. He quoted figures from the Stockholm maternity clinic which showed that actually the pregnant tuberculous woman had a rather better expectation of life than the non-pregnant tuberculous woman. He did not doubt that a very early diagnosis of tuberculosis might be of considerable value to those who desired to arrange an "irreproachable" abortion for non-medical reasons, but he hoped that as a result of the present discussion the medical sanctions for abortion, so far from being extended, would be curtailed. Every advance in medical treatment must reduce the occasions on which danger to life or health might be cited in defence of that which was, at best, an act of despair, and at worst a crime akin to murder. If any section of the profession were carried away on the wave of criminal sentimentality passing over the country he would suggest that their activities might be checked by making abortion compulsorily notifiable.

EARL RUSSELL said that, in view of the existing law, it struck him as curious that from some of the cases quoted on the medical side the practice of gynaecologists should have been extended to a degree which went far beyond the narrow consideration of risk to life or health, and amounted in many cases to relieving the patient from a very inconvenient and unpleasant time. It showed how doctors, as he had always maintained, were the high priests of modern civilization and were above the law. The doctors declared in their gynaecological discussions what it was right to do in cases of this sort, and Sir Travers Humphreys said that there was no appeal to a legal tribunal. Sir Travers said that the sole thing they had to consider was the interest of the patient. If that was the case, surely one would apply to the question of removing a foetus the same tests and considerations as one would apply to the removal of any tumour. All operations were dangerous, and Sir Travers had stressed the dangers of abortion. But in these cases of very dangerous operation the choice was generally left to the patient. The ethical view, as stated by Dr. Fairbairn, given the present state of our law, was perfectly correct and unassailable, but the ultimate ethical law was not necessarily that embodied on the statute book, and he was inclined to take the German view which Lord Riddell had quoted, in which it was insisted that the foetus was not yet an independent human being, and that every woman, by virtue of the right over her own body, was entitled to decide whether it should become one. In a matter of this sort the mother, and the mother alone, ought to be the arbiter. What was at present on the statute book was there on religious grounds, and probably could be defended on those grounds, but there was no justification for imposing those grounds on others. Great efforts were being made for the preservation of child life, and he would be the first to recognize the undoubted moral duty of the mother to do the best she could for the child

that was to be born, but that did not affect his view that the mother should be mistress of the situation, and the State, unless it said that deliberately it took a certain course for reasons of population and the like, had really no abstract right to deal with the matter. That was not the existing law, but it was his view of the fundamental ethics.

Professor LOUISE MCILROY agreed with most of what Dr. Fairbairn had said. She held also that when any abortion took place it ought to be notified to the State, just as was a stillbirth or a live birth. She knew that it was easy for those of them who were specialists in a large city to take a high ethical view, but it was not so easy for the struggling practitioner in his district when perhaps a patient of means and influence wanted him to take this course. He was inclined in such circumstances to look about for some medical excuse for performing abortion; knowing that if he refused she might be the means of greatly injuring his practice. It had been said that this was a woman's question, but the question whether pregnancy should be terminated was a moral question which affected both sexes equally. She greatly resented the assumption of some patients that they could go to the consulting room and lay down to their doctor a line of treatment in much the same spirit as they would approach the bargain counter. She was sure she was speaking for other members of her specialty when she said that none of them looked upon the induction of abortion as anything but homicide. As time went on, and methods of treatment improved, abortion would be regarded as a confession of failure, and would be practised less and less by gynaecologists. In one aspect, however, it was a woman's question—namely, in the cases of pregnancy following rape. There she would like to have legal permission to prevent continuation of the pregnancy, for she saw no reason why the woman should suffer it.

Dr. F. J. MCCANN said that an extraordinary wave of abortion-mongering had proceeded over Europe since the war. Bills were now tabled in the German, Austrian, and Swiss parliaments seeking to legalize abortion during the first three months. He was one of those who held that there was no ethical reason for procuring abortion. Unless strong opposition were taken to the first ethical loophole being made it would be disastrous to the country. The reason why abortion was spreading was because it was believed that in the early stages there was no life and that abortion in those stages was free from risk. It could not be too widely known by the public that there was life from conception onwards, and that there was grave danger from abortion even in the most skilled hands. He had seen danger arise from merely dilating the neck of the womb without the necessity of emptying it. He was inclined to criticize the lawyers for certain legal confusions. Thirty years ago the Royal College of Physicians took counsel's opinion, which was that the law did not forbid the procurement of abortion during pregnancy or the destruction of the child during labour where such procurement or destruction was necessary to save the mother's life. It was on that pronouncement that many of them had acted ever since. But there were some peculiarities about the law. One, for example, was that, whether the woman was really pregnant or not, an attempt made by another person with the idea of procuring abortion was a crime, but if the woman made the attempt herself she committed a crime only if she was pregnant.

Dr. MARIE STOPES protested against Dr. Fairbairn's statement that the movement for "constructive birth control" tended to produce a slackening of moral fibre. The ethics of abortion had not been touched by any speaker in a fundamental way. Everybody had spoken as if this was an exceptional condition in which a patient came to a medical man, and, if he refused to do what she wanted, there was no more to be said. But abortion was going on all over the country, by other than medical practitioners, in an open and barefaced manner. Thousands of persons assumed that it was the most natural thing, involving no legal or other consequences. She protested strongly against the sale of abortifacients, some of them under her own name, in shops not far from Wimpole Street. She had been to Scotland Yard on the subject, and was told that she had no protection. The law on the subject was so feeble that it could be defied by the participators in this shameless trade, who apparently could use any name they pleased in connexion with their abortifacients, and the person concerned had no redress.

Dr. BERESFORD KINGSFORD supported the view taken by Earl Russell that in fundamental ethics the mother should be the mistress of the situation. If depriving the community of potential citizens was really the offence, what about the sale of contraceptive appliances? If abortion prevented the State from having hundreds of future citizens, these appliances—as to which he expressed no opinion—prevented it from having thousands, perhaps hundreds of thousands. But the fact was that the country was getting more children than it needed. It did not need them in peace, because it had more people than it could employ; nor in war, because it had been shown that true reliance in war was not upon a C3 population, but upon the united voluntary effort of the King's dominions.

Sir BERNARD SPILSBURY said that biologically the individual must be regarded as starting life from the moment of conception. The fact of birth was a mere incident in the life of an individual. Regarded from that point of view, the only sanction for abortion that could be recognized was that the life or health of the mother was seriously endangered by pregnancy. Legally the destruction of the foetus *in utero* was not murder, but morally it certainly was unless there was justification for terminating the pregnancy prematurely owing to danger to the mother from its continuance. There could be no question that abortion was extremely rife. Probably the cases that came into court were only a small proportion of those in which abortion was procured, and the proportion that came into court was lower than it was a quarter of a century ago, partly because the skill of the professional abortionist had increased of recent years.

Dr. ARCHIBALD DONALD deprecated the view that this was purely a question for the mother—apparently not even for the father. He owed a great deal to the sex, but in these matters he was bound to say that many women seemed to have no moral sense whatever. With regard to medical reasons for inducing abortion, the cases of the kind with which he had been concerned had been, as to the great majority, cases of excessive vomiting of pregnancy; in other cases the patients were seriously ill from heart trouble or uraemia or such conditions. It would be a great disaster if the medical profession departed from its traditions in this matter.

Mr. Justice Salter's Summing Up.

The CHAIRMAN said that, looking at this question in the precise—he would not say pedantic—manner to which lawyers were accustomed, it seemed to him to narrow down to this: what was and what ought to be the law with regard to artificially procuring abortion? Every doctor desired to be within the law, and desired the law to be so framed that his duties as a citizen might never conflict with the duties of his profession. Taylor, in his *Medical Jurisprudence*, had a section headed "Justifiable abortion," but laid it down that there was no such thing as abortion justified in law, and the editor of the latest edition of that work had retained that opinion. It seemed to him (the learned judge) to be at least arguable that the Legislature, in forbidding the unlawful use of instruments or drugs, implied that there was such a thing as lawful use. Dr. Fairbairn's position was that either the law allowed, or should be amended to allow, abortion in every case where, after all due examination, delay, and inquiry, it was the considered opinion of the medical man that abortion was absolutely necessary to save the life of the mother or to prevent grave, possibly permanent, injury to her health. The mother's life, certainly; the mother's health, in the grave sense of the word, yes; and there was a third class where it was a question of the future health of the child. Suppose it became clear during the pregnancy that one or other parent was afflicted with some disease very commonly inherited, would there be medical justification for abortion? He would regard that as a very difficult case indeed. Then there were non-medical cases in which it was sought to justify abortion on such grounds as that the child would be unwelcome or expensive, that pregnancy

would interfere with the mother's social amusements, that abortion would be a means of avoiding disgrace and exposure, or—stronger in its appeal than any of these—that the unfortunate woman had been the victim of rape. Two speakers had urged that the prospective mother was the mistress of the situation. He certainly agreed that she should have more say than anyone else, but if he might put into blunter English the contention of those speakers it was that abortion should be lawful in any case in which the mother desired it or even consented to it. That seemed to him to go rather far. Here was a living thing, approaching the moment of birth, having in many senses a separate existence already, and the mother was to be at liberty, if she pleased, to have its life ended! After it was born was she still to have that right, and, if not, why not? The ethics of this question could not be considered without bearing in mind the close connexion which there always was between abortion and infanticide. In the later pagan era there was an enormous traffic in the "exposure" of unwanted children, who were taken by speculators and reared as slaves or prostitutes. He had been impressed by a phrase used by Professor McIlroy, that abortion was homicide, and justifiable abortion was justifiable homicide. If abortion were ever sanctioned outside the medical area—in the interest of eugenics, for example, or for economic, social, or personal reasons—he would have great fear that within the medical area there would arise a large class of pliant doctors who would be very easily persuaded that there were sufficient medical reasons in a given case. And in this matter, as in so many others, it would be all to the advantage of the rich, while the poor would find it more difficult to get a favourable "opinion." Some speakers had boggled at the idea of many abortions on the same woman. But if one, why not many? He believed that if it were ever proposed to extend the liberty of abortion outside very strictly recognized and limited medical grounds those who proposed such a change would find themselves up against an enormously powerful body of public opinion—a body rather inarticulate, perhaps, and influenced rather by atavistic ideas, but none the less powerful. One of the most striking features of the early Christian Church was its attitude towards abortion, which in the later pagan era had been practised enormously, and was regarded in the light of a venial wrong, much as sexual excess was regarded. The attitude of the infant Church was from the first uncompromising, and never wavered, and he was certain that if it were ever proposed to extend the liberty of abortion that spirit of unswerving opposition would rise again. The discussion had revealed the great difficulty and delicacy of the question, and certainly its profound importance, and it had been a great satisfaction to him to take the chair.

GASTRIC AND DUODENAL ULCER.

AT a meeting of the Section of Surgery of the Royal Society of Medicine on January 19th, with Mr. WARREN LOW in the chair, Professor J. M. T. FINNEY of Baltimore, U.S.A., gave an address on gastric and duodenal ulcer which was very comprehensive and included abundant references to the literature of the subject. At the end of the lecture he showed a series of diagrams and sketches through the epidiascope illustrating the operations of Billroth, Mikulicz, and others, and, in greater detail, his own technique in the operation of pyloroplasty.

Professor Finney discussed the several theories which had been advanced to account for the formation of ulcer; one of the first was the inflammatory theory advocated by Abercrombie. It was true that various degrees of gastritis were frequently found in conjunction with chronic ulcer, but there was no basis for assuming that these might be the cause rather than the effect of ulceration. In the neurogenic theory disturbance of the nerve supply of the stomach had been held to explain the various conditions associated with ulcer. Many authors had written on this subject, but so far the results had been of little value either in pathology or treatment. In favour of the circulatory object of chronic ulcer was the fact that the parts of the stomach from which the circulation had been shut off were subject to the action of digestion, and there were other circumstances which suggested a circulatory cause. On the other hand, the infrequency of demonstrable changes in the blood vessels around the ulcer, and the fact that ulcers commonly occurred at an earlier age than was usual for arterial disease to manifest itself, might be regarded as evidence against the theory. The idea that gastric ulcer started from a diseased condition of the blood vessels depended on the findings in a comparatively small group of cases. Gastric ulcer had been recorded in association with most of the diseases to which the blood vessels were subject, but in the majority of cases of gastric ulcer no changes were found in the blood vessels except those secondary to the ulcer. The bacterial theory of gastric ulcer origin had its advocates, and many bacteria had been described as the causal agent of ulcer, but for the most part the bacterial condition might also be considered as secondary. One worker at the Mayo Clinic had called attention to the localized infection of the mucous membrane by streptococci. There remained the digestive theory, but it was now generally believed that the gastric juice had little or no part in the beginning of the ulceration, and it had also been shown that when there was initial injury, this and the subsequent digestive action together, if unaccompanied by the continuance of the underlying cause, whatever that might be, were insufficient to prevent healing. The characteristic appearance of stomach ulcer was probably due, not to a specific cause, but to the action of the gastric juice, which kept clean the base and edges of the ulcer. The clean base and edges justified no conclusion as to the cause of the ulcer. Altogether, peptic ulcers probably originated from various causes acting on favourable tissue, and that was all that could be said at present. The multiplicity of methods whereby acute ulcers might be experimentally produced had tended to clear rather than to obscure this problem.

The malignant transformation of ulcers had been first suggested by Cruveilhier in 1839. The surgeon's treatment of ulcer must be profoundly influenced by his opinion as to the proportion of cases in which ulcer of the stomach might be the origin of carcinoma. If he believed that over 50 per cent. of gastric ulcers went on to carcinoma he was bound to advocate more radical procedure than if he believed the proportion to be less than 5 per cent., and it was between even wider limits than these that the estimates ranged. While the tendency towards carcinoma was generally recognized, the criteria on which opinions were based as to the likelihood of this development varied widely, and it was of obvious importance that these criteria should be standardized as far as possible. Professor Finney gave statistics to show the wide variation in numbers by different observers, and quoted with approval the more conservative estimates of Ewing, adding that there was no reason to believe that carcinomatous transformation occurred in more than 10 per cent., or at most 15 per cent., of gastric ulcers. The operating surgeon should be able to classify lesions which really fell into the two groups, simple ulcers and ulcerating carcinoma. If a surgeon was unable to differentiate these, which now and then happened, and if in addition he believed that 50 per cent. or more ulcers would go on to be carcinomatous, he would be consistently radical in his procedures; but if he was able to distinguish between these two he would have little hesitation in treating simple ulcers conservatively. Professor Finney thought that about 85 per cent. of all cases might be recognized without microscopical aid as benign. Of the remaining 15 per cent., on microscopical examination about 5 per cent. would be found utterly benign, another 5 per cent. would present recognizable carcinoma, while the remaining 5 per cent. would require microscopical study of serial sections to enable their true character to be ascertained, which even then could not always be done. His experience was that where the surgeon was in doubt the pathologist was still more uncertain, though this was no reproach to the pathologist. In these doubtful cases of stomach ulcer, as in doubtful tumours of the breast, the more common error was to call a benign condition malignant than to call a malignant condition benign.

Professor Finney, passing to treatment, said that the operations usually performed for ulcer might be considered as either conservative or radical. The conservative might be subdivided into (1) procedures directed towards local excision, cauterization, and suture of the ulcer; (2) local excision *plus* gastro-duodenostomy or pyloroplasty; (3) the latter procedures alone. The radical operation was devoted to extirpating not only the ulcer but the ulcer-bearing area of the stomach. The surgeon must be guided by the conditions found in the individual case in deciding on the character of the operation, bearing in mind, as the three main considerations, the importance of removing the ulcer-bearing area of the stomach, the efficacy of reduction of gastric acidity by a large resection, and the possibility of carcinomatous transformation. Those three points decided for or against a wide resection. Previous to any surgical operation there should be a period of preparation, unless the operation was one of emergency. He prepared his patients according to a regular routine, and in patients so prepared infection was reduced to a negative quantity. Pre-operative and post-operative care was of the utmost importance in stomach cases; the latter was always, in his experience, carried on in conjunction with the family practitioner. One of the important parts in the preparation was to instruct the patient to practise antiseptic tooth-cleansing and rinsing of the mouth for several days previous to operation. The patient was kept on sterile food, and repeated observation by various authors showed that the acid stomach would sterilize itself under these conditions in approximately forty-eight hours. This rule did not apply in cases of carcinoma of the stomach walls. Transfusions were given if the haemoglobin percentage was under 60. The points for the surgeon to bear in mind were meticulous attention to detail, complete asepsis, and the gentle handling of the tissues. Each surgeon had his favourite operation, and this was unfortunate, for he was therefore liable to practise it when, in the circumstances of the case, some other operation was preferable. Professor Finney, summarizing his conclusions, said that since the cause of ulcer was unknown, and its presence was undoubtedly a menace to the comfort and happiness, and possibly even the life, of the patient, it would appear that resection of the ulcer, where practicable, was indicated in cases in which it had failed to yield to good medical treatment. No surgical procedure of any kind should be performed on the stomach without previous consultation with a competent physician. Resection of the ulcer did not guarantee non-recurrence, though, if the resection was thorough, recurrence was very rare. That form of surgical procedure which least disturbed the normal physiological relations of the stomach and intestine, other things being equal, should be the operation of choice. Pyloroplasty or gastro-duodenostomy, associated where possible with resection of the ulcer, would appear to be preferable. The particular method must be determined by the conditions found present at the operation. The acceptance of this proposition would relegate to the second or third place the procedures of gastro-enterostomy and extensive gastric resection. In his own case the best results, both immediate and late, had been secured by pyloroplasty or gastro-duodenostomy where this was possible. Gastro-enterostomy should be regarded as an operation of necessity, never as an operation of choice. Nor was he convinced that the sacrifice of large portions of the stomach wall, in view of the vital nature of this structure, was either indicated or justifiable as a routine procedure for simple ulcer. In the presence of malignant disease, of course, the most radical procedure was the most conservative, but the same rule did not hold in the case of benign conditions.

Sir ANTHONY BOWLBY expressed to Professor Finney the appreciation of the Section, remarking that it might almost be thought that Professor Finney was a specialist in this particular branch of the subject, but, in fact, his knowledge of every other branch of general surgery was equally thorough. As chief medical adviser to the American army in the war he had done much to promote harmonious working together of British and American surgeons. Sir JAMES BERRY, seconding the vote of thanks, expressed the pleasure taken by the Royal Society of Medicine in welcoming a great American surgeon. Sir GEORGE MAKINS associated himself with the tribute, and strongly approved Professor Finney's endorsement of the rule, which had fallen more or less into abeyance, that the surgeon should act in close co-operation with his medical colleagues.

Dr. J. L. JONA (Melbourne) mentioned experiments which had driven him to the conclusion that one of the points in the pathogenesis of gastric and duodenal ulcer was, not hyperacidity, but the absence or diminution of the normal pancreatic juice. Mr. ETHELBERT FLINT (Leeds) agreed as to the advantages of gastro-duodenostomy over gastro-enterostomy. Out of 200 cases in which the former operation had been practised, in only nine had he failed to mobilize the duodenum, and the nine included four in which the adhesions were so marked that he thought it was not advisable to disturb them. The mortality was th same as with gastro-enterostomy, and the outlook appeare to be much better, for patients on whom gastro-enterostom had been performed commonly suffered a certain amount disturbance afterwards. Mr. F. A. G. JEANS (Liverpoo held that chronic ulceration, however long it had existe was not very likely to lead to malignant disease. He adde the remark that whatever they did, however slight radical the operation, there would always remain a ra of men who were "inveterate ulcerators and persiste perforators." Mr. R. P. ROWLANDS could not see th advantage of doing a partial gastrectomy for a simp ulcer. He had been a great believer in Finney's operatic for many years. Mr. A. J. WALTON viewed with apprehe sion the movement, especially on the Continent, towar these partial gastrectomies, which he thought not on dangerous but quite unnecessary. With regard to theori of ulcer formation, he considered hyperacidity an impo tant factor, and thought that a certain type of activ muscular, energetic man tended to get such hyperacidit and to increase it, by the way, by cigarette smoking.

CHRONIC NON-TUBERCULOUS INFECTION OF THE LUNGS.

AT a joint meeting of the Sections of Medicine, Surger and Laryngology of the Royal Society of Medicine o January 25th there was a special discussion on the trea ment of chronic non-tuberculous infection of the lung It was opened by Dr. L. S. T. BURRELL, who confined h remarks to three conditions—bronchiectasis, abscess of th lung, and pneumomycosis. In a mild case bronchiectas might cause the patient little if any inconvenience, and th treatment should not expose him to greater risk than th disease. The cause should first be looked for, and, if foreign body, removed. The simple means of postur drainage and creosote inhalations were often sufficient t cure. In more severe cases, if unilateral, and if the lun could collapse, artificial pneumothorax was successfu Phrenic avulsion had been practised with pneumothora especially if there were many diaphragmatic adhesions, bu in the speaker's experience had not been of much valu Aspiration and washing out of bronchiectatic cavities gav very good results; occasionally thoracoplasty was successfu but there were many disappointments. Partial lobectom by cauterization seemed to be a promising operation; bu lobectomy was extremely dangerous. An acute abscess o the lung would often yield to simple treatment by rest healthy conditions, and posture. When these were unsuc cessful artificial pneumothorax should be tried early After a time the lung could be allowed to re-expand, withou any return of symptoms. Sometimes a partial thoracc plasty became necessary. Dr. Burrell thought pneumc mycosis a rare condition. Recently, in a case with sign and symptoms of pulmonary tuberculosis no bacilli wer present, but persistent mycelia. The *x*-ray picture showe coarse mottling. The patient improved rapidly on larg doses of potassium iodide.

Mr. TUDOR EDWARDS described the *x*-ray appearance o an abscess connected with a bronchus. He thought arti ficial pneumothorax the best treatment, especially when th

abscess was near the hilum of the lung. At the periphery secondary infection of the pleura was liable to occur from breaking down of adhesions. Drainage of a bronchus was rarely satisfactory. In dealing with a case of abscess of the lung *x*-ray pictures should be taken from several directions. Drainage would be necessary for four to six weeks. There was a liability to secondary bronchiectasis. In chronic bronchiectatic abscess the bronchoscope should be used to eliminate the possibility of a foreign body. Mr. Edwards was against pneumothorax in bronchiectasis. Pneumotomy was better. The main wall should be opened with the cautery, and the cavity cauterized and packed. Sometimes a permanent fistula had been established. The cavities should be evacuated through the bronchoscope. Drainage through the chest wall was unsatisfactory. Phrenic avulsion might reduce the amount and fetor of discharge. In lobectomy the mortality was 50 per cent., and improvement in technique was required.

Mr. EWART MARTIN described the advantages of the bronchoscope in association with lipiodol injections. He noted the curious fact that in America foreign bodies were often found in the lungs, while in this country they were comparatively rare; but it was probable that many foreign bodies were overlooked. Bronchoscopy allowed of the localization of a lesion, the removal of pieces of tissue for examination, and the taking of swabs. It aided treatment for the removal of foreign bodies and for chronic infections. By its means aspiration and lavage of abscesses and bronchiectatic cavities could be carried out. Difficulties in aspirating from the upper lobe could be met by special tubes.

Dr. K. D. WILKINSON thought the etiology of bronchiectasis should always be considered. He had had little experience of foreign bodies as a cause. The disease, he thought, often began in children as a sequel to pneumonia or influenza. Early diagnosis was difficult, as there was no dividing line between bronchitis and bronchiectasis. There might be fetid pus without any dilatation being shown by lipiodol. Milder cases, especially in children, should be treated by postural drainage, creosote inhalation, and vaccines. His experience of artificial pneumothorax had been unfortunate. He had seen one success by drainage through the chest wall. The cautery was sometimes useful; and after the first cauterization there was no shock. In severe unilateral cases only surgical treatment could be of any use.

Mr. C. A. S. RIDOUT said that physicians had only recently begun to ask the [illegible]. Bronchoscopy was chiefly useful [illegible] showed a definite bronchiectatic area in one lung, or in both. Under local anaesthesia a series of bronchoscopies could be performed, one every few weeks, the tubes emptied by suction, and lavage subsequently employed. Mr. Ridout described the technique of the operation. He thought the emptying of the cavities was of more importance than the lavage. He had seen a patient die of acute oedema an hour or two after the lavage.

Mr. J. E. H. ROBERTS thought that a mistake had been made during the discussion in not distinguishing between various stages of bronchiectasis. Advanced cases could not be cured; and with improved diagnosis and treatment advanced cases ought not to occur. Prophylactic treatment should always be in mind. Cases of unresolved pneumonia and lung abscess should not be lost sight of, but carefully watched for developments. Foreign bodies should be removed early, and phrenic evulsion and vaccine therapy used where necessary. When a case was established the physician, the surgeon, the radiologist, and the laryngologist should work together. Cases were nearly always unilateral at first. If there was no cure in a few months phrenicotomy should be done as a preliminary measure. Thoracoplasty gave good results in early cases. Cauterization was a severe operation, with a mortality of 20 per cent. It might be questioned whether this operation and lobectomy were justifiable. Mr. Roberts favoured treatment by surgical crescendo—division of the phrenic first, then thoracoplasty, then the cautery, and lobectomy last of all.

Dr. F. G. CHANDLER called attention to the necessity of discriminating between chronic bronchitis, non-tuberculous fibrosis, bronchiectasis, pressure by an aneurysm, and even chronic abscess or an old empyema. Fibrosis might lead to bronchiectasis through traction on the bronchi. If progressive, the best treatment was artificial pneumothorax. The traction on the bronchi was released thereby. In other cases gomenol might be injected. Advanced bilateral basal "glove-finger" cases of bronchiectasis could only be treated by palliative measures. In a bilateral, rather advanced, lower lobe case, postural drainage and creosote had produced great temporary improvement. For other cases Dr. Chandler had used artificial pneumothorax and phrenic evulsion. He preferred to try all these measures before resorting to rib mobilization or thoracoplasty. Some cases of lung abscess cured themselves. In others treatment by artificial pneumothorax was indicated; but there was a risk of empyema. Drainage was the best treatment, if the pleura had first been made properly adherent by packing.

Mr. H. S. SOUTTAR described two cases to illustrate the need for always searching for foreign bodies. The first was that of a woman who had inhaled a mutton bone; the second case showed the advisability of exploring the chest in doubtful cases of long standing. If properly done the procedure was as satisfactory as exploration of the abdomen. Good adhesions should first be obtained by packing. A large area of the lung should be exposed. A large cavity should then be worked out with a cautery at a low temperature.

Mr. V. E. NEGUS considered bronchoscopy under local anaesthesia to be easily practicable with competent assistants. He had removed a fibroma, which had caused suppuration, from a secondary bronchus. The diagnosis of carcinoma was facilitated by the bronchoscope. Mr. Negus thought that the function of the circular musculature of the bronchioles was not sufficiently recognized, nor the part taken by swollen mucous membrane and by granulations in upsetting the normal mechanism. He showed diagrams to demonstrate the retention of pus in bronchiectatic cavities, and how irrigation might do more harm than good.

Dr. GEOFFREY MARSHALL said that the respiratory tract was well equipped with defences against infection; but that the defence might be broken down by the inhalation of a foreign body, gross structural changes, or repeated invasions by pathogenic organisms. He called attention to the bad results of prolonged drainage in empyema, and to the permanent damage sometimes resulting from acute pneumonia. He was of opinion that chronic bronchitis, localized in the upper lobes, was associated with sepsis in the nose, throat, or sinuses. He could find no mention of this in textbooks; but often the only cure for this form of bronchitis was to cure the sinuses.

Dr. HUGH THURSFIELD, who was in the chair, said that physicians had been told during the discussion that they did not send their cases early enough to the surgeon or laryngologist. The fact was that it was only during the last three or four years that surgeons or laryngologists had been able to give any help in the treatment of bronchiectasis. He thought the position of the laryngologist the more logical. He had noted also that in these cases a serious condition might sometimes develop in so short a time that it might be said that it was impossible to catch a particular case in its early stage.

Dr. STOLKIND recalled the case of a child with repeated attacks of pneumonia, in whom gangrene set in, and cauterization was attempted. The operation was unsuccessful, and *post mortem* a portion of a bone ring was found in the abscess.

Mr. TUDOR EDWARDS, in reply, dealt with some of the points discussed, and agreed with the necessity for air-tight drainage in empyema.

Mr. EWART MARTIN emphasized the advantages of introducing lipiodol through the bronchoscope. Other methods led to breaking up of the oily globules, so that under the *x* rays quite a different kind of picture might be produced.

Reviews.

HERPES.

IT is somewhat of a shock to realize that the vast amount of experimental work collected by LEVADITI in a monograph[1] reviewing the present position of knowledge about the pathogenesis of herpes is almost entirely a post-war growth. Levaditi's object is to give a detailed survey of the experimental work that has been done by himself and his colleagues, Harvier and Nicolau, and others, but he has done far more than this, for his monograph embodies the central ideas of one of the chief pioneers who have studied the nature and affinities of neurotropic viruses; and for that reason, as also because it contains his reply to recent criticisms, it will be welcomed by all who are in any way concerned with this elusive, fascinating, and rapidly developing branch of experimental medicine. The initial discovery in connexion with experimental herpes was made by an ophthalmologist, Grüter of Marburg, about 1911, who found that material taken from a dendritic ulcer of the human cornea was capable of reproducing this lesion on the cornea of the rabbit; that this herpetic keratitis was transmissible in series; and that it was due to a virus that was apparently specific and withstood 36° C., but was destroyed by exposure for half an hour to 56° C. Grüter did not publish his observation, nor did Kraupa, who confirmed it. In fact, the first publication was in 1919 by Lowenstein, who had obtained still further confirmation and had found that herpes material from a variety of sources produced this specific keratitis in the rabbit. Further confirmation by Doerr and others was now rapidly forthcoming, and it became established that the virus of herpes is capable of exciting a specific keratitis in the rabbit, materials from a large number of control cases being uniformly negative in this respect.

In October, 1920, Doerr and Vöchting noticed that rabbits affected by herpetic keratitis may develop nervous symptoms—symptoms that suggested an invasion of the central nervous system by the herpes virus. About this time Levaditi and Harvier succeeded in producing encephalitis in rabbits with a virus obtained from the brain of a human case of encephalitis lethargica, and in 1921 Blanc drew attention to the striking similarity in the effect of this encephalitis virus and of herpes virus respectively on the rabbit's cornea. Shortly after that Levaditi, Harvier, and Nicolau, and independently Doerr and Schnabel, succeeded in showing experimentally the identity of the herpes virus with that isolated by Levaditi and his colleagues from the brain of the human case of encephalitis lethargica. Levaditi deals very fully with the experimental properties of the virus of herpes, and in an historical review of the pathology of zona (as the French call herpes zoster) pays a well deserved tribute to the classical work of Head and Campbell. Consideration is given also to the result of investigations with material from cases of zona, and the conclusion is reached that the experimental transmission of this disease has not yet been achieved.

Among other interesting information and suggestive work we are told that rabbits affected by herpetic keratitis may develop an acute nasal discharge which contains the herpes virus. The observations reported as to the receptivity of man to cutaneous inoculation with herpes virus are also of considerable importance. It would seem that the greatest success was obtained in instances such as erysipelas or cerebro-spinal fever, where there appears to be a natural predisposition to acquire herpetic infection. Similarly in encephalitis lethargica the "takes" were good. On the other hand, in varicella all the attempts to produce a herpetic vesicle with material from herpes cases were negative.

It is particularly noteworthy that while Levaditi adheres strongly to the view that the virus of herpes and that of encephalitis lethargica are one and the same, he admits that it is possible that the virus obtained by him from the encephalitis brain may have been adventitious, thus affording an example of scientific candour and open-mindedness that is as inspiring as it is rare.

[1] *L'Herpès et le Zona.* Par C. Levaditi. Paris: Masson et Cie. 1926 (Med. 8vo. pp. viii + 388; 87 figures, 1 plate. 5s. 4d.)

"SHOCK-THERAPY" IN THE PSYCHOSES.

IN a volume entitled *Traitement des maladies mentales par les chocs*[2] Mlle C. PASCAL and M. JEAN DAVESNE record their extensive experience of the treatment of mental disease by the introduction of a variety of different agents into the organism in an attempt to imitate the effects of intercurrent disorders upon the psychoses. As every psychiatrist knows, these effects are sometimes remarkable, since a bodily illness, such as pneumonia or enteric fever, may bring about an amelioration or even a cure of an apparently hopeless case of insanity. The authors have applied "shock-therapy" to a large number of patients, both acute and chronic, and have utilized a number of different methods. At first the fixation abscess method, which consists in the provocation of a purulent focus by the subcutaneous injection of turpentine, was employed. Subsequently, the following agents were utilized for injection: colloidal metals; peptones; vaccines (polyvalent and aspecific); milk; nucleinate of soda; horse serum (haemostyl); and blood taken either from the patient himself (auto-haemotherapy), or from another patient in a state of remission (homo-haemotherapy). The technique of the various methods is fully described, and a description is given of the biological and clinical changes observed as a result of treatment. These therapeutic methods, it is stated, are free from danger, and have no harmful effects if the techniques indicated are rigorously carried out.

In an interesting chapter the authors discuss the manifestations of what they describe as "mental anaphylaxis," and endeavour to explain the nature of the psychopathic constitution in biological terms as a profound humoral and neuro-vegetation defect. The book is written in a spirit of hopefulness and enthusiasm, and the authors believe that the methods of investigation which they describe contain, not only the principle of the cure of the chronic psychoses, but also their secret. We can recommend this original and interesting monograph to the attention of psychiatrists.

REPORTS OF THE ST. ANDREWS (JAMES MACKENZIE) INSTITUTE.

THE third volume of the *Reports of the St. Andrews (James Mackenzie) Institute for Clinical Research*,[3] edited by Professor DAVID WATERSTON, is the first to appear since the founder's death, and Dr. Maitland Ramsay, who has devotedly undertaken the part of honorary director, gives, as is only appropriate, an eloquent account of Sir James Mackenzie's life and of those ideals in medicine which made him leave London at the zenith of his career there to take up pioneer work at St. Andrews. He compares him as "a man of many doubts" with Sydenham, and graphically describes how he delighted in astonishing visitors to the Institute by questions such as "How does cancer kill a man?" "Why does he die?"

Of the eleven other articles, the first, also by Dr. Maitland Ramsay, on ocular disturbances associated with signs of defective elimination, is not, as its title might suggest, a lecture concentrating on diseases of the eye, and should be read by everyone who desires information on the clinical manifestations of renal inadequacy, which was described by Sir Andrew Clark forty years ago. Illustrations of the effects of the condition are naturally taken from ophthalmology, and it is pointed out that toxic amblyopia exactly like that ascribed to tobacco may occur in lifelong abstainers from tobacco and alcohol. Dr. L. H. Bryson writes on the capillary system in relation to clinical symptoms, and, after summarizing recent knowledge on the subject, applies the theory of functional unit control to certain diseases. Dr. Alexander Hynd describes the observations made in the Chemistry Department of the Institute on the nature of urinary protein, specially in eclampsia; Dr. Norman M. Maclennan, late bacteriologist to the Institute, advocates the establishment of a closer

[2] *Traitement des maladies mentales par les chocs.* By C. Pascal and Jean Davesne. Paris: Masson et Cie. 1926. (5¼ × 7¾, pp. xv + 182. 2s. 6d.)

[3] *Reports of the St. Andrews (James Mackenzie) Institute for Clinical Research*, vol. iii. Edited by Professor David Waterston, M.D., F.R.C.S.E. Oxford Medical Publications. London: Milford, Oxford University Press. 1926. (Med. 8vo, pp. 227; frontispiece, 46 figures. 10s. 6d. net.)

relation between the sciences of chemistry and bacteriology, and together with Dr. J. H. P. Paton records some interesting clinical and haematological observations on mumps, such as that alterations in the total and differential leucocyte count have no diagnostic value. Dr. Paton also contributes four systematic studies made at a boarding school for girls, dealing with routine examination, the apparent size of the tonsil, the incidence of infectious diseases, and influenza. The work of the children's department is described by Dr. A. Rowand, who follows it by three studies of groups of cases collected from its records. The ischaemic type of pain, which is so well known in intermittent limp, is, in Dr. Orr's experience, much commoner than is usually believed, and cases of exhaustion are detailed by Dr. W. B. MacTier, who briefly discusses their origin. There is a well illustrated article on the radiology of duodenal ulcer by Dr. Paton and Mr. W. J. Smith, and Dr. A. Cancella d'Abreu of Lisbon, who attended the post-graduate course in June, 1925, contributes an article on viscero-sensory reflexes, and takes the opportunity of paying a tribute to the founder.

AN ATLAS OF CYSTOSCOPY.

DR. OTTO KNEISE'S *Handatlas der Cystoskopie*,[4] unlike many other works with a similar title, is really an atlas of cystoscopy. In other words, it consists of a collection of excellent coloured plates illustrating various pathological conditions of the bladder, with only an amount of text necessary to explain them. Several German handbooks on cystoscopy have already appeared, but it cannot be said that the majority of these are a credit to the country that produced the first satisfactory cystoscope. The plates in Dr. Otto Kneise's work are, however, of a higher order. Not only has the artist succeeded in portraying what he has seen through the cystoscope, but the makers of the blocks have succeeded in retaining the quality of the paintings in the coloured plates. This is by no means easy, as may be gathered from the hideous and overcoloured plates that are frequently found in atlases on cystoscopy. Another error that has been avoided in Dr. Kneise's atlas is the portrayal of rare conditions that are only met with once or twice in the lifetime of a genito-urinary surgeon. Interesting as it may be to a writer to record the discovery of an unusual cystoscopic condition, the inclusion of these rarities in an atlas of cystoscopy is of little use to the reader. What is required is the portrayal of various forms of normal bladder and of the commoner pathological conditions met with in urological practice. If the selection made by the author is to be criticized it must be on the ground that he has not been sufficiently generous in his pictures of the various types of normal ureteric orifices that may be met with. The commonest error made by the inexperienced cystoscopist is to mistake for an abnormality what is only a variation of a normal trigone, and for this reason the portrayal of the variations of which the healthy bladder is capable is of great value.

However, apart from this there is little that can be said in criticism of Dr. Otto Kneise's work. His atlas should be of great use to all students and practitioners wishing to familiarize themselves with the commoner conditions that may be met with in cystoscopic practice. The fact that the chief virtue of the work lies in the excellent coloured plates and that the text is of secondary importance will no doubt commend it to those who are not conversant with the German tongue.

HOLT'S "DISEASES OF CHILDHOOD."

The Diseases of Infancy and Childhood[5] by HOLT and HOWLAND, has established its position as a standard text-book, and the appearance of a ninth edition would in ordinary circumstances require only brief notice. But since the last edition (1922) both authors have died—Dr. Holt in 1924, after a long life, and Dr. Howland only last June, at the comparatively early age of 53. The work of preparation of the present volume was, however, complete before his death.

The first edition, which appeared in 1896, was then the most complete account of diseases of children in America, and gave a powerful impulse to the special study of the subject there. That premier position it has retained ever since, and it has widely extended its influence throughout the English-speaking world. The book's appeal was to the practising physician; it was the account of clinical experience, both in hospital and private practice; clinical phenomena were always referred to and based on pathological processes; and, wherever possible, statements were supported by the author's own statistics. In successive editions the book became a storehouse of facts, well arranged and expounded with a brief matter-of-fact precision, and drawn to moderate and well balanced conclusions. These qualities seldom fail to secure success, and in the case of this book success was rapid and lasting. Another feature of the book was its emphasis on the preventive side of medicine in childhood, and large sections were devoted to healthy growth and to the conditions of management that would secure it. As to the tangled subject of the feeding of sick infants, little space was given to theories of causation, schemes of classification, or elaborate dietetic formulae, but an adequate, clear, and helpful account was provided of the various clinical types, their pathology, their symptoms, and their treatment.

In 1911 Dr. Howland's name appeared also on the title-page, and he brought to the book his special knowledge of metabolism, biochemistry, and pathology. It was a happy alliance of the bedside and the laboratory. Holt himself in his later years turned towards laboratory studies on the dietetics of childhood. But the book continued to keep its predominantly clinical character, and under its combined authorship fully maintained its strong position, and also its original plan and arrangement. The new edition has been brought up to date and a few new subjects are included. To the world of medical science it is a notable memorial of Holt's life and work; but Dr. Howland's untimely death is a heavy loss, both to future editions and also to pediatrics.

HEREDITARY SYSTEMATIC DISEASES OF THE NERVOUS SYSTEM.

IN a work on the morphology and histology of hereditary systematic diseases of the nervous system[6] Professor KARL SCHAFFER expounds his theory that these affections are in reality due to one and the same process; their varied symptomatology depends, he thinks, on variations, in localization and course, of a lesion that is identical in all. He regards the fundamental lesion as a degeneration, and adopts the term heredo-degeneration to include the group. The theory has given rise to considerable discussion, and Professor Schaffer has spared no pains to support it by very complete and detailed descriptions of illustrative cases and a number of unusually clear photographic plates. He recognizes that the ultimate proof of heredo-degeneration must rest on the family history, but he claims that heredo-degeneration has certain characteristic features which serve to distinguish it apart from the history. A family history is not always obtainable, and, moreover, it must be admitted that heredo-degeneration may appear *de novo* by way of mutation, and in these circumstances the family history would be negative. The characteristic features of heredo-degeneration are, according to the author:

1. The presence of a particular form of degeneration.
2. Its blastodermic electivity, the ectodermal being picked out to the exclusion of mesodermal.
3. Its system-electivity, certain definite strata or functionally related groups of neuronal elements being affected.
4. Its segment-electivity, certain definite segments of the nervous system—hemispheres, cerebellum, cord, and so forth—being involved.
5. The degeneration must be in its origin endogenous in the nervous elements; the proof of the presence of an exogenous poison as the cause of the neuronal degeneration would exclude

[4] *Handatlas der Cystoskopie.* Von Dr. med. Otto Kneise. Zweite Auflage. Leipzig: G. Thieme; London: H. Kimpton. 1926. (Med. 4to, pp. 119; 18 plates, 106 figures. 42s. net.)

[5] *The Diseases of Infancy and Childhood.* By L. Emmett Holt, M.D., Sc.D., LL.D., and John Howland, A.M., M.D. Ninth edition, revised and reset. New York and London: D. Appleton and Co. 1926. (Med. 8vo, pp. xiv + 1018; 157 figures, 5 plates. 35s. net.)

[6] *Histopathologie der Hereditaer-Karl Schaffer.* Monographien und Psychiatrie. Heft 46. pp. 253; 135 figures. R.M. 24.)

a case from the group of heredo-degenerations. For instance, a lenticular degeneration of hepatic origin, although showing hereditary features, is exogenous as far as the nervous system is concerned.

The fundamental lesion affects both the neuronal elements and the glia cells. The nerve cells, in the more acute conditions, exhibit a marked swelling of the cytoplasm, with an abundant deposit of lipoid granules; the endocellular reticulum is destroyed, the Nissl bodies disappear except immediately around the nucleus, and the latter exhibits pyknotic changes. In more chronic cases the swelling is less marked and may be local within the cell. It is somewhat characteristic that the swelling, especially in the acute condition, affects not only the cell body, but also the dendrites. The branched glia cells exhibit similar changes and, in exceptional cases, may show increased fibrillation, resulting in sclerosis. The unbranched glia cells proliferate and, in the author's opinion, take part in the removal of the degenerated nerve cells. In purely chronic conditions the nerve cells appear to undergo pyknosis and atrophy, and are finally removed by the action of the unbranched glia cells. Hereditary spastic spinal paralysis may be taken to illustrate the application of the author's theory. That this disease comes under the heading of systematic heredo-degenerations is, the author thinks, shown by the following facts, which, he holds, can be demonstrated in the cases examined.

1. The neuronal elements alone are affected, to the exclusion of any causal changes on the part of the connective and vascular tissues. There is, therefore, blastodermic electivity.

2. By virtue of the primary systematic affection of the pyramidal tracts a system electivity is present; this, in cases of pure primary lateral sclerosis, is a single-system affection, but it may become a combined systematic affection if Goll's columns are also involved. But even in cases of pure lateral sclerosis there is in reality a combined system-disease, since two cortical systems are, according to the author's observations, also affected—namely, an intracortical associative system corresponding to the third layer of the cerebral cortex, and a cortical projective system, corresponding to the fifth layer and the pyramidal fibres proceeding from it.

3. Pure lateral sclerosis has its starting-point in the cerebral hemispheres, and therefore exhibits a segment-electivity.

Conclusions of a similar kind are reached with regard to hereditary chorea, progressive muscular atrophy, spino-cerebellar ataxia, Friedreich's ataxia, and the infantile, juvenile, and adult forms of familial idiocy. The author sums up the results of his observations in two propositions: (1) Systematic heredo-degeneration has a developmental basis, as indicated in the anatomical triad of blastodermic, segmental, and systematic electivity; (2) the primary seat of the affection is the neuronal cytoplasm, the lesion taking the form of swelling, with subsequent destruction of the cell. The anatomical triad constitutes the general, the swelling of the cytoplasm the special sign of heredo-degeneration in its morphological aspect. There is, he admits, a class of cases which bears a general resemblance to those of heredo-degeneration, but in which the cell changes are teratological instead of degenerative. An interesting case of the kind—one of non-familial idiocy—is described. Certain neuronal systems were absent and the general histological architecture of the brain was abnormal. Such cases have to be distinguished from those of heredo-degeneration, the degenerative changes in the nerve cells, above mentioned, being absent.

"BRAIN."

THE new issue of *Brain*[7] (Part IV of vol. 49) contains an article on the pituitary adamantinomata (from the National Hospital, Queen Square) by Drs. Macdonald Critchley and Redvers N. Ironside. These tumours arise in the neighbourhood of the infundibulum from epithelial remains of the foetal cranio-pharyngeal duct. After giving a short account of the development of the hypophysis and infundibulum the authors describe the clinical and pathological features of seven cases they have observed. Changes in the appearance of the sella turcica as seen by *x* rays are almost constant, and in addition shadows due to calcified areas in the growths are very characteristic. Acromegaly does not occur, but adiposity with infantilism or sexual regression are common, lethargy is frequent, and pressure on the optic tracts produces various defects of the fields of vision.

Dr. Richard Irvine Poston, of the Ancoats Hospital, Manchester, discusses the occurrence of vestibular phenomena in epidemic encephalitis. He describes an interesting series of cases exhibiting spontaneous vertigo in the acute or chronic stage of the disease, and includes an historical reference to epidemics of vertigo occurring at various times in France, Switzerland, and Japan, which bear a close resemblance to groups of cases arising in recent epidemics of encephalitis. The view is put forward that many of the ocular phenomena of encephalitis are due to disturbance of the vestibular nucleus or its connexions rather than to disease of the ocular nuclei. An account is given of the writer's investigation of cases of encephalitis by the Babinski-Weil tests of vestibular function. Dr. Douglas McAlpine gives an account of investigations carried out in the laboratory of the Hospital for Epilepsy and Paralysis, Maida Vale, on the anatomo-pathological basis of the Parkinsonian syndrome following epidemic encephalitis. Details are given of the pathological findings in eight cases, in which the only constant lesions were found in the cells of the substantia nigra of the mid-brain; no noteworthy changes were found in the basal ganglia, though in the earlier stages of the disease these ganglia are affected by the inflammatory process in common with the greater part of the brain and brain-stem. Some results of faradic stimulation of the cerebellum in monkeys and armadillos are extracted from the unpublished writings of the late Dr. R. H. Clarke, who collaborated for several years with Sir Victor Horsley in his experimental work. Movements were obtained especially of the head and eyes, but also of the trunk and limbs. Very strong stimuli were required when applied to the cortex, but when the needles were inserted deeply towards the roof of the fourth ventricle movements were obtained with small currents. These papers show that, contrary to their original and published opinion, Horsley and Clarke concluded finally that all these movements were due to spread of the stimuli to motor centres in the vicinity of the cerebellum, and that they afford no evidence for the existence of motor centres in the cerebellum itself, either in the cortex or the intrinsic nuclei.

[7] Published in London by Macmillan and Co., and in New York by the Macmillan Company. Yearly subscription in this country 24s., to be sent to Messrs. Macmillan, St. Martin's Street, London, W.C.2. Price of this part 6s. net.

NOTES ON BOOKS.

THE fifth German edition of the classical work by Professor HAJEK on the *Nasal Accessory Sinuses*[8] was recently reviewed in this JOURNAL (July 31st, 1926, p. 204), and the appearance of a translation will be welcomed by his English-speaking colleagues. The translation by Dr. HEITGER and Dr. HANSEL has been well done, and has certain advantages over the original, being divided into two bound volumes, making it more attractive in appearance and more convenient to handle, whilst the printing, paper, and reproductions of pictures are of excellent quality. Much of the information which has been added in the form of footnotes might with advantage have been embodied in the text. The most instructive portion of the book is perhaps the exhaustive and well illustrated study of the anatomical variations of the accessory sinuses; proper appreciation of the pathological changes and their surgical treatment must have such a foundation as is here provided. The various methods of taking skiagrams of each group of sinuses are described in detail and their interpretation discussed. The explanation of anatomical details is assisted by plates illustrating various difficult points. Diagnosis and treatment are discussed in connexion with each group of sinuses, the author basing himself partly on long personal experience and partly on the voluminous literature of the subject. The whole is so well balanced and arranged that everything is in proportion and free from the repetition which is a common defect of big books owing to a desire to leave nothing unsaid. The book is quite without a rival in its particular subject.

[8] *Pathology and Treatment of the Inflammatory Diseases of the Nasal Accessory Sinuses.* By Professor Dr. M. Hajek. Translated and edited by Joseph D. Heitger, A.B., M.D., and French K. Hansel, M.D. M.S. Fifth edition, completely revised and enlarged. London: H. Kimpton. 1926. (Sup. roy. 8vo: Vol. I, pp. xvi + 294; 7 plates, 130 figures. Vol. II pp. viii + 408; 56 figures. 75s. net the two volumes.)

On first opening Dr. BALYEAT'S book on *Hay-Fever and Asthma*[9] the reader cannot fail to be struck by a series of illustrations, designed to impress upon his memory certain common causes of these complaints. Thus there is a family of cats sunning themselves on the steps just prior to entering the house, whose inhabitants may suffer in consequence. Then there is a boy playing with a dog, a frequent cause of his asthma. Next comes a horse, Kentucky bred, to show that horses may cause asthma, and so on. The last of the series depicts a lady seated before a mirror. Her right hand is stretched out to pick up the powder-puff from the dressing-table, for she is about to powder her nose, and the orris-root in the powder may give her asthma. These and other illustrations equally ridiculous and conspicuous give an altogether false impression of the book, for the text is excellent. Dr. Balyeat practises in Oklahoma, and gives a thorough account of the local flora in relation to asthma and hay-fever, laying stress on the fact that the important plants are inconspicuous with air-borne pollen, whilst plants with brilliant flowers, such as roses, pollinated by insects, are often unjustly blamed. It is clearly important that those who make a study of these diseases *should be acquainted with the botany of the locality.* The book is intended to give an account of the nature and treatment of asthma and hay-fever in simple language mainly for the benefit of patients, and the author has accomplished this very well.

Drs. ROBERT DUPONT, ROGER LEROUX, and JEAN DALSACE have provided[10] in a succinct and convenient form a guide to the clinical methods of obtaining material for examination in the laboratory, as, for instance, by the performance of lumbar and pericardial puncture, both of which are illustrated by diagrams. Pathologists and bacteriologists, but the latter perhaps in particular, often suffer from the manner in which specimens are collected and transmitted to them, and they will no doubt desire that this handbook should have a wide circulation. The first part deals with haematological, bacteriological, and other examinations, and the remaining portions with biopsies. Professor G. ROUSSY, in his preface, says that this is the first time that a book of the kind has described the technique of biopsies with the immediate microscopical examination during the course of an operation of tissues, so as to inform the surgeon, for example, whether he is dealing with an innocent or malignant growth. This may be true of France, but the latter method has often been advocated and described in this country, especially by Dr. E. H. Shaw, and in America. The risks that have been attributed to the method are discussed, and in connexion with the belief that generalization of a malignant growth may be thus started the authors state that they have done thousands of biopsies without observing this accident. It is perhaps a natural sign of the times that the price is stated, not in francs, but as two shillings.

Mr. GEORGE MULLINS, in his book *Unemployment*,[11] advances the view that unemployment has resulted from failure to co-ordinate agricultural with industrial production. If the agricultural labourer produces food, not only for himself, but also abundantly for the industrial dweller in towns, and so sets a high standard of living, he utilizes the services of many craftsmen, with the betterment of efficiency and enrichment of the lives of the members of the community. For a long time past agriculture has been depressed, wages are low, and labourers flock to towns; with the result that there is really a world shortage of food, and the advance guard of civilization starves. And the form of its starvation is unemployment. The remedy Mr. Mullins proposes is that the industrial worker shall be made to resume a proportion of his original work of food production. New factories should be built on large areas of land, and the workers housed in cottages with a half to one acre of ground to each house. The workman would be employed for a seven-hour shift in the factory for five days a week. A certain number of hours each week would be devoted to the cultivation of his land for the production of vegetables, fruit, honey, pigs, rabbits, and goats. The labourer would be required to acquire the freehold of his cottage, and would only be allowed to dispose of it to another labourer working on similar terms to himself. He would also be given a share in the profits of the company, not in cash, but in shares, which he would not be able to sell while he retained his work, though they would become equal to ordinary shares if he left his job. It will be seen that Mr. Mullins combines in his remedy several modern efforts for improving the lot of the worker; and that his views on food shortage are borne out by Sir Daniel Hall's remarks at the meeting of the British Association last summer.

Dr. KURT SCHNEIDER'S studies of registered prostitutes[12] consist of two parts. The first contains details of seventy women arranged in twelve psychiatric groups according to their degree of impulsiveness, restlessness, and mental defect. The second presents a composite picture of the life-history of these women considered under the three periods of childhood, the stage between leaving school and registration, and their life under the control of the police. An appendix by Dr. LUISE VON DER HEYDEN gives detailed information of the subsequent history of 62 of the 70 women; 19 were still under police control eleven years after completion of Dr. Schneider's inquiry, while 43 had been taken off the books in consequence of marriage or the assumption of a respectable occupation. The work is a valuable contribution to the psychological study of the prostitute, and as such will appeal alike to the psychiatrist, the criminologist, and the sociologist.

PREPARATIONS AND APPLIANCES.

A Safeguard for the Water-cooled Mercury Vapour Lamp.

Dr. M. WEINBREN, medical officer in charge of the ultra-violet department, Queen's Hospital, Sidcup, suggests an arrangement for protecting the water-cooled mercury vapour lamp (Kromayer type) from the destruction which would result if the lamp was allowed to burn without there being circulation of water. To prevent this accident he inserts a red lamp in parallel with the Kromayer lamp, and controlled by the same switch. This red lamp is suspended from the water-tap, and lights up when the Kromayer lamp is switched on. If, through carelessness or accident, the water has not been turned on, the lighting-up of the red lamp immediately draws attention to the tap. Dr. Weinbren adds that, while an apparatus could be designed which would automatically switch on the water as well as the current, this apparatus would be rather complicated and expensive. The red pilot lamp serves the same purpose equally well, and only costs a shilling or two.

ROYAL MEDICAL BENEVOLENT FUND.

AT the last meeting of the committee forty-four cases were considered and £769 13s. 6d. voted to forty applicants. The following is a summary of some of the cases relieved.

Widow, aged 36, of M.B. who died suddenly in November last. Left with one child, aged 2, entirely unprovided for. Has recently had a major operation herself, and will not be fit for work for six months. Late husband had to help to support his mother and sister, which debarred him leaving adequate provision for his wife and child. Emergency grant of £10 sent, and a further sum of £26 in four instalments was voted.

L.R.F.P. and S., aged 84, with wife, aged 80, who is paralysed and helpless. Only income £12 from investments; old age pension £52. Allowance of £90 per annum from younger son, who also pays for the maintenance of elder son in a mental hospital. Elder daughter, aged 51, is at home and looks after her parents, while the younger earns 25s. a week in a warehouse. Rent and rates amount to £36 per annum. Emergency grant of £10 made, and a further sum of £40 in twelve instalments voted.

Daughter, aged 52, of M.D. who died in 1874. She lost money on a boarding house which had to be given up at the end of nine months. Teaches music, but from lack of pupils asks the Fund for assistance. She is lame. Voted £18 in twelve instalments.

Widow, aged 65, of L.R.C.P.Ed. who died in 1919. Applicant has worked as a deaconess for years until August last, when she had to give up on account of leg trouble. Total income £90 per annum. Rent 11s. a week. Voted £26 in twelve monthly instalments.

Widow, aged 45, of M.R.C.S. who died last November. Left with girl of 14 and boy of 12. No private income, and only £100 from insurance. Has had £150 from mother-in-law, but it is uncertain whether this will be continued. Now lives in three rooms at a rental of 12s. a week. Voted £20.

Widow, aged 53, of M.D. who died in December last. Left with six children aged 11 to 21. Only the eldest one earning. One son studying the law, others at school. Voted £20.

M.R.C.S., aged 73, has had to give up work on account of old age and deafness, and has just lost an allowance of 10s. a week through the death of a sister. Has the old age pension. Wife has a post in a school. Children unable to help in any way. Voted £40 in twelve monthly instalments.

Subscriptions may be sent to the Honorary Treasurer, Sir Charters Symonds, at 11, Chandos Street, Cavendish Square, London, W.1.

The Royal Medical Benevolent Fund Guild still receives many applications for clothing, especially for coats and skirts for ladies and girls holding secretarial posts, and suits for working boys. The Guild appeals for second-hand clothes and household articles. The gifts should be sent to the Secretary of the Guild, 58, Great Marlborough Street, W.1.

A MEDICAL REVIEW OF SOVIET RUSSIA.*

V.—THE MEDICAL PROFESSION, SOVIET SCIENCE, AND SOVIET SANITATION.

BY

W. HORSLEY GANTT, B.Sc., M.D.

(Formerly Chief of the Medical Division of the American Relief Administration, Leningrad Unit.)

PART I.

SOCIAL CONDITIONS, 1914-1922.

IT will be interesting to the physicians of other countries to know of the personal life and work of their colleagues in the U.S.S.R. (Union of Socialistic Soviet Republics). Before describing their present condition I shall give a brief review of their life during the past decade.

After 1914 there was a gradual decline in the standard of living in Russia. By 1917 deprivations had become chronic. Then the exhaustion of two revolutions, blockade, famine, and disease precipitated wholesale misery, from which Russia is just beginning to recover. What corresponded to the worst period in the rest of Europe was only the prelude to the Russian experiences. It is important to remember not only the intensity of this suffering, but its duration. A barefooted, tattered Russian physician said to me in 1922, on receiving an English newspaper, "It has been so long since I have even heard of anything civilized it seems like hearing from another world." Another doctor said he was so accustomed to going all day without anything to eat that he never felt hungry (in 1924) when he missed a meal. In Russia as early as 1916 there were four meatless days a week, and sugar had entirely disappeared in many districts. Salaries had been raised 20 per cent., but the cost of living had doubled or trebled.[1] During the great war there were fewer Russian doctors but more Russian wounded than in other countries.

When fighting with Germany ceased the Russian physician was mobilized into whatever army was occupying his section of the country—whether white, red, or allied. This civil war and proletarian revolution, which lasted with some intermissions until 1922, left the population without medical assistance, and country medical clinics were closed and disorganized.

The declared purpose of the second revolution was socialism through the elevation of the proletarian, and the destruction of the social superstructure. It brought disaster to all those who lived on a higher level, and lowered the standard of life to that of the peasant.† The doctor's position was more hazardous than the peasant's, as shown by his higher death rate.

When fighting was over and Communistic rations were abandoned (end of 1921) the physicians returned to their former positions, often without remuneration. The official salaries were too little to live on, and were often paid several months late, and the population had no money to pay for private practice. If any valuables had been retained, they were sold for food. Well known professors and clinicians became destitute, and in 1918-20 many physicians entered the hospitals with hunger oedema, and death from starvation became frequent. Though the official ration often did not suffice for one person, it had to be divided among the family, and a medical practitioner, in order to sustain himself, had to hold several appointments, hurrying from one to the other on foot through the snow, going several miles to get a pound of bread.‡ At one time it was the duty of a physician to work in at least three places, and if he did not he received a compulsory appointment.

Later on, in spite of the shortage of doctors in Russia, there was unemployment in their ranks because they could not pay for a State licence as there was no paying practice. Some gave language lessons, did manual labour, etc. In April, 1923, 400 physicians were registered as unemployed in Leningrad.

During the period of epidemics the death rate of physicians was much higher than that of the rest of the population. A dean of a university told me that "they were taken ill in masses. One city lost 42 physicians out of 300 in one winter." In a single clinic of Moscow in a few days there were eight cases of typhus, ending with the death of Professor M. and his assistant. In another clinic Professor S. was the only one to survive. In one of the clinics of the Military Medical Academy (formerly the clinic of Professor Sirotinin) every doctor died from typhus.

"In Odessa, in one month of the spring of 1922, out of 92 doctors engaged in examining children for the American relief kitchens, sixteen caught typhus. This is the more spectacular side; the more important part of it is that in many of the districts where the after-effects of the famine are worse, there is not more than one doctor for 100,000 persons." (S. M. Keeny.)

During the war there were 24,000 doctors in Russia. About 50 per cent. of them suffered from typhus, and 3,000 died of this disease alone. This high mortality has been attributed to a peculiar susceptibility of the nervous and vascular systems in physicians. Professor Chernoroutsky says, in a personal communication: "Other infections which have no special effect on the nervous system give an average prognosis, but typhus, meningitis, etc., have a bad prognosis. For in medical men the mortality of typhus between the ages of 50 and 60 was 87 to 100 per cent., compared with 33 to 50 per cent. for other people." The following table from the Obookhoff Hospital, Leningrad, shows their high mortality compared to others.

Occupation.	Number.	Morbidity (Typhus).	Mortality (Typhus).	Percentage Mortality of Total Number.
Surgeons	24	12=50%	3=25%	12.5%
Physicians ...	80	40=50%	8=20%	10.0%
Sisters	95	60=52%	10=16%	9.6%
Servants	416	91=25%	28=23%	6.6%
Nurses	827	257=30%	30=11%	3.6%

Dr. Semashko states that "during the height of the epidemics of typhus and relapsing fever practically 100 per cent. of the doctors on the Eastern Front were stricken, and their mortality was 70 per cent."[2]

The increased morbidity and mortality of the physicians can be explained, according to Professor Grekoff, by their extreme exhaustion and by the hard conditions of their life. But in spite of his difficulties the fact that the physician had some useful work to perform acted as a mental stimulant. A well known physiologist, who had had hunger oedema in 1920, told me that his work had kept him alive. In many families I noticed that those who had nothing to do died sooner of starvation than those who were working, although they had the same amount of food. As a contrast to the physician was the pitiable mental condition of those who had no work.

Scientific Work.

Scientific work almost ceased.

"Constant anxiety for food and fuel, endless waiting in queues, a half-starved beggarly existence could not but strongly affect the life of scientists. From 1918 to 1920 they, as well as all the other inhabitants of the cities, never left their houses without a bag on their backs in which to bring home bread, potatoes, etc., received as rations. An eminent professor lived the winter through in his bath-room, as it was the only place that could be heated. It was a usual thing for men of science to carry up to their apartments wood and water, and to empty the sewage, as the lavatories did not function."

---

* Previous papers on medical and scientific work in Soviet Russia by Dr. Horsley Gantt were published in the BRITISH MEDICAL JOURNAL in 1924: I, A Review of Medical Education in Soviet Russia, vol. i, p. 1055; II, Hospitals and Health Conditions, vol. ii, p. 336; III, Scientific Work, vol. ii, p. 533. The first part of section IV, on "Change in type and incidence of disease," was published on August 14th, 1926, p. 303; Part II of this section was commenced on October 23rd (p. 747) and concluded on October 30th (p. 802).

† For an accurate, first-hand account of contemporary peasant life, see M. G. Hindus, *Broken Earth*, 1925, International Publishers, New York.

‡ A professor in a large university told me he was delighted on one occasion to receive two pounds of butter for a lecture, after walking eight miles.

Professor Bechtereff states that the neuro-psychical energy of an organism decreases with the decrease of nutrition. A general depression of personality results, with passivity and a lack of will power. In 1923 one of the survivors wrote:

"Besides resulting in a high mortality among the scientists in Leningrad—the centre of mental life of the country—these hard years decreased the capacity and energy of those who survived."

Leaving aside the difficulty of working in unheated laboratories, examinations could not be done owing to the lack of gas, water, and illumination. There was a total absence of both Russian and foreign literature.*

"In order to write down one's observations one had to use grey paper of a bad quality which was stealthily bought from speculators (trading being prohibited). The home-made ink was usually prepared out of some dye hardly suitable for the purpose."

Many scientists left Leningrad or were employed in some other kind of work. But,

"notwithstanding all the terrors, scientific life did not cease altogether. During the most difficult periods one could see men of science working in their overcoats, fur caps, and snow-shoes. Half-starved men continued to carry out their experiments on half-starved animals. Dead animals were cooked and fed to the living. After an operation the animal was often taken home for the night to be kept near the stove with the investigator."

Scientific meetings were held, although the members had to go on foot and to sit in overcoats. Often a lamp or candle had to be used instead of electricity. By the end of 1919 scientific life began to revive. In spite of the bad conditions several new scientific societies were formed during these years and important work was carried on.

In some institutes lack of money and equipment continued. Professor X. told me that when he went to a university library to work during the winter of 1923-24 the ink was frozen, and that during part of the time when he was lecturing the temperature was 10° C. below freezing; but the students continued to attend in spite of the cold.

The members of the Russian medical profession during these years gave themselves freely and often without any pay. They rendered the people no small assistance in checking the epidemics and carrying on other sanitary measures. Although foreign relief supplied much of the material and sometimes the organization, the actual work was done by the natives, as the number of foreigners was too small to count for more than a stimulus.

Worthy of mention is the uprightness and unselfishness of the Russian physicians during these horrible and hopeless years. This was at a time when the strain of living was so great that some of the population were driven to eating human flesh and even killing members of their own family. In distributing large quantities of relief supplies through the Russian physicians, I never knew of a single case of theft by them, although they were in dire need. There were many cases of heroic unselfishness, such as the following from Vologda, a town of 50,000 inhabitants near Archangel. On an inspection trip there we found the chief surgeon, among others, in great need. He had not had a new suit or overcoat for ten years. He was wearing trousers that were more patches than pants, and out of his salary of less than a pound sterling monthly (in April, 1923) he had a wife and nine children to support. On returning to Leningrad we sent him (and some other doctors there) a relief clothing package. A few days later we received a gracious letter saying that he had given the package to a colleague more needy than himself, enclosing a letter of thanks from the recipient.

As late as September, 1925, I have seen research workers paying one-half of their monthly salary for paper to chart their results, and many professors give part of their salary to support the laboratory where they work.

Present Conditions.

Since 1922 there has been a gradual improvement in both living and working conditions. Fighting and famine are now past, and order has been restored. The currency has been stabilized, and salaries, though small, are paid regularly. As the former war communism has been abandoned in a certain degree, many of the more famous doctors are now better off. Unemployment of doctors has disappeared, except for those recent graduates who prefer living in the cities to working in the villages. A full professor receives now 80 to 150 roubles (£8 to £15), an assistant about half as much, the younger clinical clerks 20 to 40 roubles (£2 to £4). Young scientific workers receive nothing, or from 7 to 100 roubles (less than £1 to £10). These salaries are without rations. Manufactured articles and clothing are considerably more expensive than in England; plain food and room rent are somewhat cheaper. Besides the loss of personal property and private income, professional salaries have dropped to one-half or less, and the cost of living has doubled or trebled compared with the pre-war standard. The population is divided into categories; the cost of lodgings, train tickets, telephones, etc., depend upon a person's category—that is, whether he is in Government employ, a member of a union, in private business, and so on. In 1926 (June) the cost of living had risen about 40 per cent., and salaries about 30 per cent., over 1925; on foreign articles there is a prohibitive duty (300 to 2,000 per cent.); for example, a lemon cost in the summer of 1926 as much as 8 shillings.

The physician's condition is considerably better than in 1922-23, when his daily income was equal to seven times his tram fare, or one pound of sugar, and his yearly salary equal to the cost of two overcoats.

Even at present it is impossible for a person with a family to do more than stave off actual starvation on the official salary. However, he supplements this; for during the past few years the Russian physician has learned many ways of making two ends meet. In the first place, most of the eminent professors have three posts, in spite of the ruling that no one may teach in more than two places. A few write textbooks.* Those not so eminent give language lessons, etc. Prominent clinicians have regained their practices and are making a comfortable living.† Those physicians who are old or cannot obtain outside work are still in dire circumstances; no one has become rich. I do not know of a single doctor in Russia who possesses a motor car. Automobiles owned by the Government are, however, at the disposal of the officials of the public health department. Communists receive 193 roubles monthly, in addition to many privileges, and have some other opportunities of earning money. A prominent Communist doctor who occupied several positions told me in 1925 that the maximum he was able to earn was 400 roubles a month. This general lack of wealth mitigates, by comparison, the misfortune of the poorest. Living in Russia is cheaper than the costs indicate, because the standards of life are lower and wants are reduced to a minimum.

When I asked a Ukrainian doctor in 1925 how he managed on his salary he replied, "By not eating much and going hungry." To one with an Anglo-Saxon appetite it does seem that the Russian physician gets along remarkably well on little more than weak tea at frequent and irregular intervals. The need for dressing is also reduced to a minimum, although it may be due to traditional tendency or personal preference rather than present finances that some appear at work without socks and shirts in the summer. The doctor also buys few books or journals, and

* "When a foreign journal reached Petrograd, those who desired to read it wrote their names in order and patiently waited the happy hour when their turn came." From December, 1918, there was only one medical journal in the whole of Russia for the next year.

* All textbooks are censored, accepted, and printed by the Soviet Government. Seventy-five roubles are paid for sixteen ordinary textbook pages, 20 per cent. of which is paid when the contract is signed, 60 per cent. when the manuscript is completed, and 20 per cent. when the book is published. As the book is the property of the State, there are no further profits for the author. Professor Pavlov received 25 roubles for each 8,000 words of his book on conditioned reflexes. For the special articles the Soviet Government desires written it pays, I understand, as much as ten times this amount.

† There are no rules prohibiting professors, the chiefs of hospitals, etc., receiving patients at their homes. The fee for an office visit is 1 to 5 roubles, and for a house call 2 to 20 roubles. A former surgeon to the Tsar's family told me that in 1925 he received 10 to 100 roubles for a major operation. Bills are not sent in Russia, but the patient (or his family) hands the doctor what he considers the proper amount as he leaves the house. Semashko states, "private practice in Soviet Russia is entirely free, although it is now not an important source of income, and it continues to decrease rapidly."

his amusements are limited. If his wife is lucky or clever, she too does some kind of remunerative work, such as teaching.*

Vacation and Recreation.

The lack of recreation and vacation has been trying to the Russian physician. It was out of the question for him to go to the theatre, club, etc.; for if any were open he had no money.† Except for the past three summers few, including Communists, have had any vacation for six to ten years. Professor Pavlov was two summers without a vacation. A Russian scientist whom I met in Denmark in the summer of 1924 told me that that was the first time he had been out of Leningrad for ten years. He was then travelling on the proceeds of a book he had just written. It is difficult to realize the strain of ten years without a rest or change even when one works under the most ideal conditions in the laboratory and lives comfortably at home.

There have arisen, however, many co-operative schemes which make life simpler and cheaper, such as rest homes for the summer. The Soviet Government bears the expenses of delegates to congresses, etc., and gives some of the eminent doctors and scientists money to go abroad for three to six months. The Kubu (director M. Leberde) was organized by the Soviet Government to extend aid to the scientists. At present it maintains an excellent club-house in Moscow, which may be used without fee by all scientists, and at which meals are provided at actual cost.

The extreme conditions of life of the Russian scientists may be considered a matter of historical interest, and the present exceptions are parallel to those of other countries when the general economic state is taken into consideration.

(To be continued.)

INTERNATIONAL LIST OF CAUSES OF DEATH.

As late as 1893 no two countries in the world used exactly the same forms and methods for the statistical classification of the causes of death. For international comparison of the death rates, for the public health, and for epidemiological purposes a uniform system of nomenclature was so obviously essential that in 1893, at the session of the International Statistical Institute held at Chicago, the late Dr. Jacques Bertillon, the distinguished French demographer and, we believe, the brother of the well known inventor of the method of identification by physical measurements, presented a draft of a classification of the causes of death for international use, which had been prepared by a special committee. This draft was at once generally approved, and, indeed, adopted promptly by several countries; it was further decided to keep the classification abreast of scientific knowledge by decennial revisions at the hands of an international commission appointed by the various participating countries. These meetings for revision were subsequently held in Paris in 1900, July, 1909, and in October, 1920, with Dr. Jacques Bertillon as permanent secretary-general. He was the originator and up to his death, soon after the last meeting of the International Commission, the presiding and guiding genius of this important undertaking.

After the second decennial revision the United States Bureau of the Census and this country both brought out in 1911 "A Manual of the International List of Causes of Death," and the same course has been followed after the third revision (1920) by the United States in 1924 and by this country in 1926. The delay in the issue of the present edition of the English manual is due to various circumstances, special to the British edition, in addition to the death of Dr. Bertillon. Dr. T. H. C. Steavenson, Superintendent of Statistics, General Register Office, adapted the 1911 manual for use in England and Wales. The present edition (1926) of the Manual,[1] which is adapted for Scotland, and Northern Ireland also, is issued, on the authority of the Registrars-General for England and Wales, Scotland, and Ireland, with a view to providing, for the use of public health officers, the medical profession generally, and any others interested, an official statement of the practice in force with regard to the classification of the causes of death in the several parts of the kingdom. There is still a lack of uniformity in the international methods of death registration, and at the third revision in 1920 a resolution allowed each country a certain amount of latitude in adapting to its own special requirements the model of an abridged list approved at the conference for revision.

The Manual enables the names of diseases as certified according to the method of the country to be assigned to their correct place in the international list of causes of death. Thus the General Register Office advises medical practitioners to use in their death certificates those terms only which are recognized in the Nomenclature of the Royal College of Physicians of London, for when this is done there is, as a rule, no difficulty in referring deaths to their proper heading in the International List of Causes of Death as now adopted for use in the Registrar-General's reports. At an international conference of vital statisticians held at Geneva in August, 1925, it was recommended that all the countries using the International List of Causes of Death should publish similar manuals containing lists of terms employed in certifying the cause of death. The Health Section of the League of Nations has now taken up the matter of improving the correlation of the death statistics of the various countries using the international list, for, according to the high authority of those responsible for the present manual, comparability "under present conditions must be to some extent apparent rather than real."

The International List of Causes of *Death* does not pose as an academic or scientific classification or proper nomenclature of *diseases*, but is intended to be a practical working list whereby the compilers of statistics can correctly tabulate the causes of death. The Nomenclature of Diseases drawn up by a joint committee appointed by the Royal College of Physicians of London is much more elaborate than the International List of Causes of Death; it includes certain symptoms and morbid states which seldom or never prove fatal; it is therefore clear that there is a considerable difference between a nomenclature of diseases classified as far as may be possible on a scientific basis and a list of causes of death. The difficulties in constructing a satisfactory classification of diseases on the ever-shifting sands of medical knowledge are so great that critics of the official Nomenclature have not been wanting, and there is full justification for the view that the time for any final attempt has not arrived.

The history of the official Nomenclature of Diseases is not without interest. The famous Dr. William Farr, who has been said to "have made statistics literature," finding Cullen's system, then in general use in the public services, not up to the knowledge of the time and unsuited for statistical purposes, prepared a "Statistical Nosology" (Registrar-General's reports, 1839-40), and in 1853 wrote a report upon a classification for death statistics to be used in all countries. In 1859 the Royal College of Physicians of London set up a joint committee to bring out a Nomenclature of Diseases, which duly appeared in 1869, and, being "subject to decennial revision," came out again in 1884, 1896, 1906, and 1918, so that in the natural course of events another, the sixth edition, is due next year. Whether any preparations for this are being made we do not know. As it has in the past been brought out for, and at the expense of, the Government, it may well be that the financial conditions are unfavourable. In the meanwhile the revised "Manual of the International List of Causes of Death" gives the medical man clear directions, politely called "suggestions," respecting the way in which death certificates should be filled up.

* One young scientist of my acquaintance who receives 10 R. (£1) monthly gets food from his mother in the country, and the chief of the laboratory gives him a few roubles from his salary of 60 R. monthly. Another, working in the laboratory of Professor Pavlov, lives by raising fancy dogs at home.

† In 1923, when I had the privilege of accompanying Professor Pavlov to the theatre, he told me he had not been for five years. A Russian physician abroad in 1924 told me he had not eaten in any Russian hotel or restaurant since 1917. Another said that his favourite recreation days was working in the laboratory at night.

British Medical Journal.

SATURDAY, JANUARY 29TH, 1927.

CANCER, RESEARCH, AND COMMON SENSE.

THE British Medical Association has been fortunate in obtaining the consent of Sir Berkeley Moynihan to deliver the first of the popular lectures it has instituted and associated with the name of Sir Charles Hastings, the far-sighted provincial physician who founded it nearly a century ago. He and the friends with whom he was associated were careful to define its objects so widely that the instruction of the public comes well within its scope. The President of the Royal College of Surgeons of England, who has often before taken an active part in the work of the Association, made an opportune choice in taking "cancer and how to fight it" as his subject, and we make no doubt that, though addressed to the public, his lecture will be eagerly read by members of the profession. It is published in full in the SUPPLEMENT this week. The discussion of the cause of cancer has both a pathological and clinical side, and on the latter no one can speak from an experience more extensive and varied than the lecturer. Most of us recognize that it has a sociological side also, and we shall have the better grounds for this conviction after studying the Hastings Lecture, and the admirable speech of the Minister of Health (p. 207), which made it plain that he has a sure grasp of the problem and of the way in which it should be attacked.

Increased interest in cancer has been forced on the modern civilized world by the increase in the number of cases, as shown by statistics, and by the fact that, as the lecturer said, probably few families escape it for three consecutive generations, so that nearly everyone knows of some relative who died of it. A demand that the increase shall be stopped and the number of cases diminished is therefore only in the nature of things. The public has lost the old fatalistic attitude towards disease, and is now very well aware that the best hope of prevention lies through knowledge of the cause. It has therefore been ready to listen to suggestions, some of them very dogmatically expressed, on the cause of cancer. Medical literature is encumbered by a mass of writings consisting of positive assertions about the cause of cancer which, when examined, turn out to be no more, or very little more, than assertions and reassertions of individual belief. A theory more or less plausible is propounded: all the facts that are in agreement with it are gathered together, and those which are not are ignored or brushed aside. For some cancer is an infectious disease; this, they hold, is obvious, and point to certain analogies between it and, say, syphilis. To others it is equally obvious that cancer is not infectious, that it is not due to the introduction of some external agent. Some find its cause in overeating, generally of meat; others in a failure of tissue nutrition attributable to a perversion or gradual lowering of the process, and these can point to the fact that cancer, though it may occur at an earlier age, is in the main a disease of later middle life. The public, as has been said, is deeply interested, and these assertions and theories have been finding their way into the newspapers and popular magazines. This is, of course, very natural, and, regarded from one aspect, very desirable, since the public needs to be educated; evil in it is working its own cure, for many of the theories are mutually destructive, and the intelligent layman is now disposed to ask whether any of them are of any value. A distinct change is also, we think, to be observed in the attitude of the skilled journalist, who, though he may publish the confident assertions so profusely made, has grown far less ready to father them and to blame the medical profession for not accepting them and acting upon them.

Sir Berkeley Moynihan discussed with great common sense—if we may use the phrase without appearing impertinent—the knowledge we have, both positive and negative, and drew two conclusions as to what can be done for and by this generation. For the man and woman of to-day the essential fact is that cancer is always at first a local disease—not a general, or, as some quacks advertise, a "blood disease." Therefore the treatment of cancer to-day is by removal of the primary lesion. If we do not yet know how to prevent cancer we know how to prevent its extension in the individual. The lecturer did not tell the public baldly, as some in search of a slogan have done, that "cancer is curable." He said that it may be cured if certain conditions are fulfilled, but that they can be fulfilled only if the individual knows and acts upon ascertained facts. The fear of cancer is very general and very deep, and often has an effect directly opposite to that which common sense would dictate. Elsewhere in this issue is the report of a case (p. 187) in which a woman suffering from a non-cancerous disease endured extreme pain and discomfort rather than go to a doctor for fear that she might be told that it was cancer. This state of apprehension is so common as to be within the experience of every practitioner, and the lecturer quoted with approval Mr. Hastings Gilford's statement in his recent book to the effect that this attitude must be wrong, and that failure to force the real facts into the consciousness of the public causes "the subject to assume forms in the imagination more terrifying than they actually are." As Sir Berkeley Moynihan said, "fear should be the fear of delay." Therefore it is that the Yorkshire Branch of the British Empire Cancer Campaign, the establishment of which with a sufficient capital sum at its disposal is so largely due to his own efforts, has realized the necessity for the education of the public.

His second conclusion is that a strenuous effort must be made at once to discover by research—"ceaseless research"—the cause or causes of cancer. Here much more is being done than even a few years ago. The hand was first placed to the plough by the clinicians and histological pathologists of the last quarter of the last century, who found out, with much labour, what the cancerous process really is. The ground was turned over again by the Imperial Cancer Research Fund, which applied the experimental method; and now research is being eagerly prosecuted in many places and by clinical, epidemiological, and laboratory methods. In London there are, in addition to the fund just mentioned, the wards and laboratories of the Cancer Hospital and of the Middlesex Hospital; in Manchester there is the organization of which an account was given a fortnight ago (p. 116); and for the whole country, or rather for the whole Empire, there is the British Empire Cancer Campaign, of which the Yorkshire scheme is a branch; in Liverpool, as our readers know, a courageous plan for treating cancer, when already present, is being tested. The three methods of research—the epidemiological, the clinical,

and the laboratory, must go hand in hand. Hitherto the clinical has gone ahead, but he who would seek to put it into antagonism with the others will do the cause no service.

CONTROL OF INFLUENZA.

IN February, 1919, during the great influenza pandemic, which surpassed all its predecessors in severity, the Local Government Board drew up a memorandum on the prevention of influenza. On July 1st of that year the Local Government Board became merged in the newly created Ministry of Health, and in the following December, when a further outbreak seemed possible, the Ministry issued to sanitary authorities a revised version of the memorandum. Now, seven and a half years later, in view of the prevalence of influenza in certain countries abroad, and the "possibility" (now unfortunately fulfilled) of the epidemic spreading to this country, a third edition has been prepared, and copies were circulated on January 19th.[1] The returns of deaths due to influenza are a good index of the severity of an outbreak, but the extent of its spread cannot be gauged like that of a compulsorily notifiable infection. It appears from a circular accompanying the memorandum that "neither the incidence of, nor the mortality from, influenza in this country is at present such as to cause serious anxiety." Nevertheless, though the cases are for the most part mild, as compared with those of 1918-19, all the indications, public and private, go to show that influenza is now very prevalent in England, and the number of deaths attributed to it has in fact been rising week by week. A concise statement of present knowledge about this baffling complaint, such as the Ministry of Health has now issued, is therefore timely.

As before, the memorandum is arranged in three parts. A short introduction, historical and epidemiological, precedes some general observations on influenza and the individual action required in times of epidemic, and these are followed by an outline of the steps that should be taken by sanitary authorities to combat outbreaks and assist the victims. The introduction has been brought up to date in various respects, mainly by showing in tabular and graphic form the history of influenza in England and Wales since 1919. The second part contains a good deal of new matter, and we note that some suggestions for personal protection have been modified. Thymol is now favoured for gargles and mouth-washes; face masks are no longer advised; and as for prophylactic vaccines, "such direct evidence as the Ministry has been able to collect does not encourage an optimistic view of their value." But it is in the paragraphs on the bacteriology of influenza that the great uncertainty of our present knowledge of this disease is most clearly brought to light. Negative statements abound. Thus: "No sure means are yet available for distinguishing the 'common or influenzal cold' from true influenza, nor is it yet certain that they are distinct clinical entities." And again: "No conspicuous advance has been made recently in our knowledge of the bacteriology of influenza. Opinion is still divided between adherents of Pfeiffer's theory and those who believe that the true causal agent is some other organism—probably a filter-passer. . . . The present outlook as to the primary causation, therefore, is not particularly hopeful."

If to know how little we know is the beginning of wisdom, then some progress has been made since the last pandemic. We have learnt that our ignorance about influenza is even greater than was supposed. But negative findings in a matter of such great public importance should act as a spur to further extensive and intensive research into the natural history of the disease, and into the character and life-history of its infecting agent. Prophylaxis fights with one hand tied behind its back so long as etiology is obscure. It is true that some attempt is made in the memorandum to answer the question why bacteriological progress is so slow, but this philosophical explanation will give cold comfort to the practical sanitarian. The common-sense advice on what a patient should do when attacked is helpful. Equally sound is the advice to local authorities on the steps they can usefully take during a wave of epidemic prevalence, with its insistence that the most important thing for them to do is to organize the available nursing service and provide help for influenza-stricken households. But all this only emphasizes the need for some practical and efficient method—based on knowledge—for preventing and controlling this readily communicated infection of the upper respiratory passages. It is therefore gratifying to read that since the *Report on Influenza* was published by the Ministry of Health in 1920 other investigations have been initiated under its auspices, and "a comprehensive study is being made of the flora of the nose and throat, with particular reference to the organisms associated with the complications of influenza, and the possibility of correlating changes in their distribution with the occurrence of epidemics." The present outbreak should afford opportunities for this kind of field work on a much larger scale than was possible under the war conditions of the last pandemic.

The essential difficulty of the situation is well put in the following passage: "As yet we do not know the nature of the living virus to which influenza is due. The laboratory has not yet given us a specific form of treatment of influenza or of protection against it." Since, moreover, no drug has been proved to have any specific influence as a preventive, it seems clear that a satisfactory means of checking the spread of this infection must await further and more intensive research.

VENTILATION OF "ALL-ELECTRIC" HOUSES.

WHEN Leonard Hill shut up his devoted hand in the hermetically sealed glass chamber till the percentage of oxygen had fallen so low that a match could not be ignited, he found that the uneasiness produced was at once relieved by the cooling effect of air set in motion by electric fans, and so proved in a convincing manner that the discomforts felt in vitiated air are due to its warmth and humidity, which interfere with the normal heat-loss of the body and so derange its function. The use of fans has been found beneficial for crowded halls, and in warm climates for habitations, but this can scarcely be recommended as conveniently applicable to the ordinary dwelling-house in this country. We therefore have recourse to ventilation, which replaces the warm moist air inside by cool and relatively dry outdoor air. Ventilation is good not only for comfort, but also as a safeguard against the spray infection by which many communicable diseases are spread, since the entering fresh air sweeps all ill things away, including the floating germs. The circulation of air through inhabited rooms has thus a double value. One of the best means to secure it is a flue or shaft opening permanently into the open air. In the form of a chimney its use has hitherto been practically universal in Great Britain for all houses great and small. With a good fire

burning the average chimney may circulate 20,000 cubic feet of air an hour. Without a fire, so long as the chimney retains its heat, a current of air moves steadily up it. Even after it has cooled down the blowing of the wind across its free opening acts as an aspirator for the room and keeps the air in continual movement. In rooms without chimneys it is recognized that an alternative arrangement is necessary. Some building by-laws require the provision of a shaft in the ceiling, leading vertically to the open, to give the chimney effect. In the "all-electric" houses now being erected by certain local authorities, which need no fireplaces and so possess no chimneys, air-bricks set in the walls of rooms are the device proposed. The value of these appliances has been questioned. In view of the well known capricious action of most aids to natural ventilation, it is perhaps somewhat rash to dogmatize beforehand on the probable conduct of the air-bricks, but whether they act as inlets or outlets, or both, they seem, on the whole, unlikely to be such effective exhausts as the chimney or ceiling shaft, and therefore less fitted to keep the air of rooms in gentle and steady circulation. It may be conceded that the cost of special ventilating shafts for these subsidized houses would be a serious item; it may be conceded also that windows are supplied which people can open if they will; yet the impression remains that the "all-electric" house, bereft of its chimney for reasons of economy, will prove to be less adapted for automatic ventilation than the old-fashioned dwelling with its grates and coal fires, which decorate the air of our cities with smoke wreaths and produce our winter fogs. The prevalence of air-communicable infectious disease in "all-electric" houses, should they be erected in sufficient number to afford material for an inquiry, may throw an interesting light on this question in the years to come. *Experientia docebit.*

LABORATORY SERVICES IN AUSTRALIA.

WE referred lately[1] to the measures now in prospect in Australia to carry out the recommendations of the Royal Commission on Health for the more effective co-ordination of the health services of the Commonwealth and its constituent States. An estimate of the advances which have already been made, as exemplified in the provision of serums, vaccines, and other biological products, may be formed from a recent account of the Commonwealth Laboratory Service prepared by the acting Director of the Laboratory Division of the Commonwealth Department of Health. Prior to 1914 Australia was almost entirely dependent on supplies of biological products obtained from overseas. During the war these imports rapidly diminished, till an acute shortage of diphtheria antitoxin brought matters to an issue, and a scheme was devised by Dr. J. H. L. Cumpston for the establishment of laboratories, situated within the Commonwealth, for the production of these substances. After preliminary work during 1917 at the Melbourne Hospital, the Central Laboratories at Royal Park, Melbourne, were occupied in 1918. In 1921 a further movement was begun to set up clinical pathological laboratories in country stations throughout Australia. There are three such laboratories now in Queensland, one in each of the remaining four mainland States, and one in New Guinea, making eight in all. They act in co-operation with the Institute of Tropical Medicine at Townsville in Queensland. The work of the Commonwealth Laboratories at Melbourne includes the preparation of serums for the treatment of diphtheria, anthrax, cerebro-spinal fever, pneumonia, puerperal fever, scarlet fever, gonorrhœa, influenza, and tetanus. Vaccines are produced for the prophylaxis or cure of cholera, dysentery, typhoid fever, influenza, whooping-cough, plague, and other diseases. Insulin also is prepared in large quantities, and the need for a continuously available supply is kept prominently in view. Another staple product is calf lymph for vaccination against small-pox. The laboratory staff carry out epidemiological inquiries, and investigate epizoötics, such as plague in rats, which threaten the health of the community. Milk, food, water, and sewage are analysed; bacteriology is taught, and medical officers and technical assistants are trained in public health work. Among pathological researches the cancer problem has engaged attention. The eight country laboratories perform diagnostic work in bacteriology, biochemistry, and clinical pathology, investigate local outbreaks of disease, and act as local distributing stations for the biological and other products of the central laboratories at Melbourne. Some, having x-ray plant, can extend to surrounding medical practitioners the resources of radiology. Some have also made special inquiries into particular problems—such, for example, as diphtheria at Bendigo, miner's phthisis at Kalgoorlie, lead poisoning at Port Pirie, and a typhus-like disease at Toowoomba. The laboratory system of the Commonwealth is fundamental to the health of Australia. Alike in its centre and in its country branches, it reflects much credit on those who devised it and first set it in motion. In ten years it has won independence for Australia in the matter of biological products—an asset of primary importance whether in peace or war. Centred at Melbourne and ramifying into the States, it suggests to the mind the value of co-operative action, and by its mere existence may serve as a stimulus to that further co-ordination between the Commonwealth and the States for health purposes which the Royal Commission has advised.

THE RATE OF THE CIRCULATION.

MANY efforts have been made to devise a method for determining the rate of the circulation in man. For various reasons the laboratory methods have not been applicable; that of Fick, for instance, needed a sample of blood drawn by puncture from the right ventricle. Several modifications, by which the gas content of the venous blood was obtained indirectly, were devised in order to apply the method to man, but the results were not consistent and reliable. More recently a method involving the inhalation of nitrous oxide was suggested by Krogh and Lindhard. This, however, did not yield consistent results in practice. Quite recently Henderson introduced a method depending on the inhalation of ethyl iodide, which would seem to be easy of application and to give consistent results. It has been used at the London School of Medicine for Women, and Professor Cullis and her colleagues, Olive Rendel (Riddell Research Fellow of the Obstetrical and Gynæcological Unit) and Ellen Dahl, believe that it is capable of wide clinical application.[1] A similar experience has been reported with the same method in Germany. In order to estimate the rate of the circulation the following data are necessary: (1) the volume of inspired air; (2) the concentration of ethyl iodide in inspired air; (3) the concentration of the ethyl iodide in the expired air; and (4) the concentration of the ethyl iodide in the alveolar air. The solubility of ethyl iodide is such that its absorption depends entirely on the flow of blood through the lungs. The amount absorbed in the experiment is far below the threshold of any pharmacological action. It is so thoroughly destroyed in the body that the venous blood reaching the lung may be regarded as free from ethyl iodide. The distribution between the air in the alveoli and the blood is such that the amount in the alveoli needs to be multiplied

[1] *Journ. of Physiol.*, lxii, I, p. 103.

by 2. The amount of ethyl iodide in the various samples of air can be very accurately estimated by passing the air over iodine pentoxide. The difficulty at the moment is to obtain with the apparatus designed by Henderson a real sample of the alveolar air, and Dr. Cullis found it necessary to check the sample so obtained against those obtained by the Haldane-Priestley method; that in use tended to give too low values for the CO_2. Apart from this criticism, which probably can readily be met, the method is said to be easy, readily applicable, and to give consistent results. The actual calculation of the circulation rate is derived from the fraction $\frac{a}{b}$ = circulation rate. The numerator (a) is got by multiplying the volume of inspired air per minute by the difference between the content of ethyl iodide in the inspired and the expired air. The denominator (b) represents the content of the alveolar air in ethyl iodide multiplied by 2. The result is usually expressed as the stroke index—that is, the output per beat in cubic centimetres per kilogram of body weight. For a normal man at rest Henderson got a stroke index of 1.5 to 1.8. In the recumbent posture this rises to 2 c.cm.; when standing it drops to 1 c.cm.; during vigorous exercise it may reach 3.5 c.cm. Dr. Cullis and her colleagues obtained a figure of 1.7 c.cm. for the stroke index of women at rest. The method should have considerable clinical value if further experience justifies the claims put forward.

NASAL OBSTRUCTION AND JAW DEVELOPMENT.

Few structures in the human body have been submitted to so searching a scrutiny as the jaws, a fact which is well evidenced in Dr. Sim Wallace's Cartwright Prize essay on variations in the form of the jaws, which has now been published.[1] To mention only the lower jaw, precise investigations have been carried out to elucidate the why and wherefore of variations as regards size and form, not only of the whole bone, but also, by separate researches, of its individual parts—its body, ramus, coronoid and condylar processes, angle, alveolar border, mental process, mylohyoid ridge, genial spines, and teeth. In many instances these researches have been conducted with a precision which is remarkable; for instance, it has been estimated that the breadth of the dental arch in bottle-fed infants is narrower than in breast-fed children by a fraction of a millimetre. The subject is the more interesting owing to the varied standpoint from which it has been approached. For the anthropologist the lower jaw has always had a great attraction; to the biologist it affords many fascinating problems; to the physiologist it presents numerous instances of the correlation of form and function; while to the medical practitioner its importance in connexion with such conditions as pyorrhoea and oral mal-hygiene is now well recognized. One of the most interesting sections of Dr. Wallace's essay is that relating to the growth of the alveolar processes in the vertical direction and the height of the palate. It has been customary to refer the well known facial deformities associated with the presence of adenoids to the habit of mouth-breathing and the pressure of the cheeks on the dental arches. It has been supposed that when the posterior nares are blocked by adenoids there results a cessation of the rhythmic increase and decrease of pressure in the air sinuses, which is assumed to occur during respiration, and that defective expansion of the maxillae, high palate and narrowing of the face, and other deformities observed are due to this circumstance. The author is inclined to reject this theory for more than one reason. Statistics have shown that in a thousand normal children the facial deformities are almost as frequently met with as in children who had been operated on for pronounced adenoids, proving, apparently, that the deformities and the adenoids are independent phenomena. Dr. Wallace is disposed to attribute the deformities to deficient action of the masticatory muscles in early life, resulting in imperfect growth of the jaws. Defective action of these muscles in the growing period leads to overeruption of the molar teeth and heightening of the alveolar processes anteriorly and of the palate. This, with the defective development in the size of the jaws, leads to the production of the narrow, hatchet-shaped face which has been attributed to the presence of adenoids. The hatchet face is commonly found in cold and damp climates, where the nasal passages become blocked, more or less habitually, long before adenoids cause any obstruction. The congestion of the mucous membrane and the discharge not only impede respiration, but indirectly interfere with the due exercise and development of the muscles of mastication. The practical deduction from these observations would seem to be that the proper treatment both of adenoids and the facial deformities is prophylactic, and should be directed towards the removal of all conditions which interfere with the due exercise of the masticatory muscles in infancy. We have referred to one point only in this interesting essay; other sections, dealing with such subjects as the effects of pressure and tension on the growth of the jaws, the post-natal developments of the jaws, and the mechanism of production of superior and inferior protrusion and the open bite, are hardly less interesting. The whole subject, with its numerous and somewhat complicated data, is handled with exceptional lucidity.

[1] *Variations in the Form of the Jaws.* By J. Sim Wallace, M.D., D.Sc., LL.D.S. London: Baillière, Tindall and Cox. 1927. (Double roy. 16mo, pp. xii + 265; 84 figures. 17s. 6d. net.)

ST. HELENA.

A CORRESPONDENT has sent us a copy of the *S. Helena Diocesan Magazine* for December last, which is edited and printed by the Rev. L. C. Walcott, the vicar of Jamestown. This little monthly of fourteen pages resembles a parish magazine, but it is the only thing in the way of a newspaper that is published on the island. It is well known that St. Helena is a volcanic island whose origin has impressed upon it its picturesque and rugged character. It has a population of little more than 3,500, and, judging from the magazine, the principal occupations of the islanders are growing and preparing New Zealand flax from the familiar *Phormium tenax* and playing cricket, for the programme for a season of less than three months includes twenty matches. The account given of the flax mills displays a darker side of the picture. An editorial paragraph states that the hours of labour are sixty-six a week, yet these long hours are not objected to by the workers, because it is piece-work. But the writer says that these hours have a bad effect, and he attributes the prevalence of weak hearts among the people to this cause. Certainly eleven hours is much too long for a night shift, and probably both employers and employed would benefit by a shortening of the hours of labour. The vital statistics of St. Helena, as far as they can be gathered from the record of baptisms, marriages, and burials for August and September, are satisfactory. There were 15 baptisms, 10 marriages, and 7 burials (3 of females and 4 of males, the latter including an infant 6 days old). Excluding the last named, the aggregate age of the three males was 183, and of the three females 125 years, giving a very unusual ratio, but the numbers are obviously too small to furnish any trustworthy average. Beyond these statistics there is no mention of the health of the island, from which we may conclude that no unusual sickness existed. The editor, however, has extracted from the St. James's Church Books a note of a small-pox scare in 1789 and of the measures then taken to protect the people of the island. The

Governor at that time was Colonel Robert Brooke, who wrote a letter to the vestry meeting warning them of the necessity of taking measures to prevent the spread of small-pox, which had been brought to the island by shipping. He reminds the vestry that: "It was argued I suppose that ships heretofore had come into harbour with small Pox on board and the very Clothes of the Sick washed without infection spreading, that of course no such Distemper could ever get footing amongst us." He went on to recommend unanimity and equanimity and the measures advised by the surgeons, Messrs. Kay and Dunn. These included isolation of the sick in a special hospital and postponement of inoculation of the susceptible population till it was seen if the infection spread, and these recommendations were adopted. We have no information as yet as to the subsequent history of this threatened epidemic. We hope that Mr. Walcott will publish the results of further inquiry in a subsequent number of the magazine. In 1789 the island was a possession of the Honourable East India Company, and flourished on the trade of furnishing supplies to shipping, but after the opening of the Suez Canal and the consequent decline of the sea traffic round the Cape of Good Hope it fell upon evil days, so that at present only about thirty vessels call there annually. The introduction of the phormium flax industry and of lace-making has increased the prosperity of the community. St. Helena, which boasts a St. Paul's Cathedral, is an episcopal see, of which the diocese includes the islands of Ascension and Tristan da Cunha, that lonely island about which an annotation appeared in our issue of January 1st (p. 28). Opportunities of the Bishop's visiting his flock and the newly appointed vicar of St. Mary's on Tristan are very rare, but communication with Ascension, which has a population of over 1,400, is direct and regular.

SLEEPING SICKNESS IN A FRENCH COLONY.

FRENCH Equatorial Africa extends from near the tropic of Cancer to five degrees south of the equator. It touches Lake Chad, and includes the Cameroons and the Middle Congo. As stated in a recent account of French overseas medical services, it is at present the scene of an outbreak of sleeping sickness of very great severity. This disease, transmitted to man by the tsetse fly, though uncommon in French West Africa, is widely endemic in the equatorial colony. In all districts south of Fort Archambault it is creating such havoc as to challenge the resources of the local administration. In Upper Shari, of 101,195 persons examined, 4,518 had sleeping sickness. In Ibenga-Motaba the corresponding figures were 51,679 and 2,996. For individual villages in Middle Logona the endemic index has ranged from 35.71 to 90 per cent. Economically and in general this visitation has had disastrous results. Saiak, for example, once a thriving post and possessed of a factory, is now derelict. Dr. Huot, who is familiar with the country, has remarked that in all seriously infected areas virulent outbreaks of trypanosomiasis are preceded by political disturbance. Exactions by chiefs, rivalry of races, or the inherent turbulence of the tribes produce conditions which may amount to anarchy. Cultivation lapses; regular villages are abandoned, and their whilom inhabitants wander through the bush in continual fear of their enemies. Malnutrition soon overtakes them; their resistance to the fly-borne trypanosome is lowered, and as a result their endemic infection assumes an epidemic form. The view has been held that in these stricken areas people flee from their villages to escape from an epidemic already loosed among them. Dr. Huot's observation is to the opposite effect. The flight precedes the epidemic outburst, and is its determining cause. The campaign against sleeping sickness in French Equatorial Africa was organized in 1921, when the infected territory was divided into centres, each with a mobile sanitary detachment. The prophylactic measures adopted are therapeutic, preventive, and administrative. The therapeutic line of attack has had most success. It is the elimination of trypanosomes from the peripheral blood of patients by six separate injections of atoxyl at intervals of ten days. Its rationale is obvious: a patient so treated, though bitten by a tsetse fly, is not a source of infection. The preventive measures include clearing the undergrowth which the fly frequents, wearing puttees, using mosquito curtains, and proofing river steamers with wire gauze. Among the administrative measures are the resettling of villages, the collection of infected communities in accessible places, the supervision of labour, and the control of migration. The prophylactic centres now number twelve. The medical personnel is forty-two, and will be raised to fifty. The control of sleeping sickness in this wide region, four times the size of France, makes high demands upon the devotion of the officers engaged in the work. The progress of the campaign will be watched with interest in England, which has similar problems in adjacent fields.

THE STEAM CAUTERY IN TREATMENT OF SKIN AFFECTIONS.

AN interesting demonstration was given at the meeting of the Section of Dermatology of the Royal Society of Medicine on January 20th with the steam cautery devised by Mr. H. S. Souttar, on the suggestion of Dr. J. H. Sequeira, for the treatment of large fungating carcinomata of the face difficult to deal with by direct surgery. The arrangement used consisted of a small boiler, heated by motor fuel, the steam from which passed through the flame, and emerged in a superheated condition. An applicator, which could be of any diameter, was screwed on to the end of the steam nozzle, the steam keeping this applicator at a constant temperature of 100° C. Mr. Souttar demonstrated the action of the cautery on a piece of meat, which showed definite coagulation within one minute. He said that penetration took place at the rate of about one inch in ten minutes. He had used it for a tumour of the face six inches in diameter. He showed two cases in which epithelioma had supervened upon lupus, and in which, after treatment in this way, there was no deformity. When a growth of the face was being treated a finger placed in the mouth prevented the process from being carried too far. Mr. Souttar's most remarkable result with it was in the case of a large burn, caused by x rays, on the epigastrium, in which he had to excise a block of tissue 4 inches in diameter. A clean first-intention wound was produced, and there was only a line such as would be left by an upper abdomen operation when the patient returned home. He thought the apparatus might have a wide application in dermatology. Dr. Henry Semon showed four cases which he had treated with Mr. Souttar's apparatus. One was a patient with lupus vulgaris of the face and neck of twenty years' duration; another had epithelioma of the ear of four years' duration, and after diathermy perforation of the cartilage had occurred, and the condition came again; another was a hairy mole, which developed a keloid formation, for which radium was being applied; and the fourth was a case of epithelioma at the external angle of the orbit. He had found that the apparatus quickly checked haemorrhage. Dr. Sequeira said that he could confirm all that had been said of the method by Mr. Souttar and Dr. Semon. He asked whether it would be safe to use the method when ether was the anaesthetic, bearing in mind the serious accidents which had happened with ether when diathermy was carried out. One great advantage of the method was that the operator had it completely under

control. Mr. Souttar, answering several questions, said that the apparatus was commercially available. There was no risk of exploding ether when using the apparatus, as the applicator never rose above the heat of steam; even when oxygen was being used there was no such risk, and the apparatus was being made even safer by introducing wire gauze, after the principle used in the safety lamp for miners. The rate of penetration could be taken, roughly, as inversely proportional to the square of the distance. For such a condition as spider naevus the application would be only momentary. Haemorrhage did not follow when this method was used, and there was absolute control with it. He did not see why it should not be used to cause haemostasis in deeper regions of the body, such as the bladder, and it seemed specially adapted for treating carcinoma of the cervix.

STRANGEWAYS MEMORIAL.

T. S. P. STRANGEWAYS, whose premature death we recently recorded, has left a widow and seven children, the five youngest of whom are still being educated. It is known to many that any part of his income which was not required for household expenses was habitually used by him to assist the Research Hospital. The immediate needs of the family have been met by subscriptions from friends in Cambridge, but a larger sum will be required to complete the education of his sons, the eldest of whom is in his second year at Trinity Hall. During the last thirty years many Cambridge medical men have been taught by Strangeways the essentials of pathology, and may feel that this is an opportunity of expressing their appreciation of these services, of his additions to medical knowledge, and of his scientific work. Cheques should be drawn to Lloyd's Bank, Cambridge, and crossed "a/c Strangeways Memorial Fund." They may be sent to the manager of the bank, Mr. G. F. C. Gill, who has kindly consented to take charge of the account, or to Sir Humphry Rolleston, Southfield, Cambridge, or to Professor H. R. Dean, Dr. M. Donaldson, Dr. G. P. Bidder, Dr. L. E. Shore, or Dr. Cobbett. A meeting will be held at the Royal Society of Medicine at 5 p.m. on Wednesday, February 2nd, at which all those who sympathize with this appeal are invited to be present.

A RETROSPECT WITH A PURPOSE.

PROFESSOR RICARDO JORGE, Director-General of Public Health at Lisbon and delegate from Portugal to the Office International d'Hygiène Publique, who is due to take part in the discussions of the International Sanitary Conference to be held in Paris next May, has, like a knight of old, proclaimed his credentials before entering the lists. He has reprinted in the *Archives* of the Central Institute of Hygiene at Lisbon some previous pronouncements of his to serve as a reminder of the stand which he made in the past on questions proposed for debate at the meeting in Paris. This publication will doubtless be effective for its ostensible object, and at the same time will make a wider appeal, since it reviews in a lucid and cogent manner epidemiological topics of general interest. Professor Jorge is against any tightening of the regulations for the control of sea-borne yellow fever. The disease is in full retreat in its own endemic areas; what need for rigour elsewhere? Stegomyia, its vector, is common in Portugal, yet between 1860 and 1921, though twenty-nine ships brought yellow fever to Lisbon, a quarantine officer and half a dozen dock labourers employed on board the ships concerned were the only persons infected. Of these twenty-nine ships twenty arrived before 1880, none after 1911. This well marked decline is ascribed, among oth *x* causes, to the increased ber of iron ships. The old-time wooden ships were good ding places for stegomyia: it does not survive the voyage in the bilges of iron steamers. Professor Jorge lays stress on the epidemiological distinction between the pneumonic and the bubonic types of plague. Nosologically, he says, there is but one plague; epidemiologically its two forms are different diseases. Pneumonic plague, unlike bubonic plague, is primarily and solely pulmonary. It is transmitted from person to person without intermediary. It is readily controlled by isolation of the sick and contacts. It prevails in cold climates, though not restricted to them. Further, there is no question in its prevalence of symbiosis with any other organism. In particular, it has nothing to do with concurrent influenza. It is usually preceded by bubonic cases, though not invariably. Professor Müller and his assistants died of pneumonic plague at Vienna in 1898 from a direct laboratory infection: there were no preliminary glandular seizures among them. Owing to the fact that these and other pronouncements were originally uttered in course of debate, much of the reprint is controversial in form. The arguable points will come up at Paris in May. In the meantime it may be permitted to refer to Professor Jorge's views on general policy. They are on broad lines. Regarding interference with persons or goods as applied to infected ships, his opinion is that the means should fit the end but should not overstep it. He deprecates needless restriction of trade. "Hygiene," he says, "is a social question, and must keep touch with other social interests. The circulation of wealth is the basis of all well-being, and therefore of health also."

THE EPIDEMIC OF INFLUENZA.

EXPERT epidemiologists find reason to hope that the worst has been seen of the present recrudescence of influenza, although the number of deaths attributed to it have increased. The notifications of pneumonia were declining for the country as a whole in the week ending January 15th. The deaths attributed to influenza in London during the last three weeks were 72, 137, and 197; in the whole of the great towns of England and Wales, 172, 326, and 470. The age distribution of deaths has been that which, with the immensely important exception of the great pandemic of 1918-19, has been usual in outbreaks of influenza—namely, that the brunt has been borne by the elderly. The regional distribution of deaths shows that, so far, London and its environs have suffered more than other parts of the country.

THE HALF-YEARLY INDEXES.

THE usual half-yearly indexes to the JOURNAL and to the SUPPLEMENT and EPITOME have been printed; they will, however, not be issued with all copies of the JOURNAL, but only to those readers who ask for them. Any member or subscriber who desires to have one or all of the indexes can obtain what he wants, post free, by sending a postcard notifying his desire to the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1. Those wishing to receive the indexes regularly as published should intimate this desire.

WE much regret to announce that Dr. T. Ridley Bailey died on the morning of January 25th. At the last meeting of the Council of the British Medical Association a message of sympathy was sent to him at the nursing home in which he had been operated upon. We hope to publish an obituary notice next week.

THE thirteenth annual conference of the National Association for the Prevention of Tuberculosis will be held at the British Medical Association House, Tavistock Square, London, on June 30th and July 1st.

THE HASTINGS POPULAR LECTURE.

CANCER AND HOW TO FIGHT IT.

LECTURE BY SIR BERKELEY MOYNIHAN: ADDRESS BY THE MINISTER OF HEALTH.

ALL the seats in the body of the Great Hall of the British Medical Association House, and all but a few in the back gallery also, were occupied by an audience—chiefly of lay people—on Monday evening, when Sir BERKELEY MOYNIHAN, Bt., President of the Royal College of Surgeons, delivered the Hastings Popular Lecture. The hall seats 700—a figure to bear in mind in view of the opening sentence with which Sir Berkeley startled his audience, that if the law of averages held good, one hundred of those present would die of cancer. The text of the lecture is published in this week's SUPPLEMENT. The perfect elocution of the speaker, assisted by microphone and amplifiers, made every word clearly audible at any point in the hall.

The Minister of Health (Rt. Hon. NEVILLE CHAMBERLAIN, M.P.), who was accompanied by Mrs. Chamberlain, presided, and he was supported by the President of the Association (Mr. R. G. Hogarth, C.B.E., F.R.C.S.) and Mrs. Hogarth, the President-Elect (Sir Robert Philip), the Chairman of the Representative Body (Dr. H. B. Brackenbury), the Deputy-Chairman (Dr. C. O. Hawthorne), the Treasurer (Mr. Bishop Harman) and Mrs. Harman, Mr. McAdam Eccles, F.R.C.S., Mr. E. B. Turner, F.R.C.S., and other members of the Council of the Association. Among others on the platform were the Right Hon. Lord Dawson of Penn, Sir StClair Thomson, Sir Robert Jones, Bt., Mr. G. H. Walmisley (Chairman, Public Health Committee, London County Council), and Colonel Sir James Magill (British Red Cross Society). A telegram from Sir Harold Mackintosh (Chairman of the Executive of the Yorkshire Cancer Campaign), was handed to Sir Berkeley, wishing him, in the name of his friends of the campaign, a great meeting.

The Minister of Health.

Mr. Chamberlain said: We have come here to-night to take advantage of a unique opportunity—the opportunity of hearing the views of one of our greatest surgeons upon a subject which is of the very first importance and interest to the nation. Of all the diseases known to us none is looked upon with greater repulsion and apprehension than cancer, partly because of its nature, partly because of the mystery which surrounds its origin, but most of all, perhaps, because it appears to be marching on in a sort of irresistible progress, taking a greater toll of victims from our midst year by year. In 1850 the deaths from cancer were recorded as about 300 per million living; in 1900 as 800 per million, and in 1925 as 1,336 per million, so that in the short space of two generations or less the death rate from cancer appears to have increased fivefold. These figures are the more remarkable when you contrast them with those pertaining to other diseases. Forty years ago the death rate from tuberculosis was four or five times that from cancer; to-day the cancer death rate is about one-third greater than that of tuberculosis. Making allowances for certain qualifications, these figures still justify the general public anxiety, and make it necessary that we should use all our resources in fighting this great evil. In that fight everybody must take part—the Ministry of Health, the local authorities, the research investigators, the medical profession, and the general public. As Minister of Health I am directed by Act of Parliament to take measures for the prevention and cure of diseases, and also to undertake "the collection, preparation, dissemination, and publication of information and statistics relating thereto." In the case of cancer we cannot at the Ministry of Health do anything in the way of treatment, and there is very little, so far as we can tell, that we can do in the way of prevention. What we do is to collect from every possible source information about cancer, its cause, nature, and action, and the methods of treatment. We get that information from all kinds of sources—researches undertaken by organizations and individuals, hospitals, general practitioners, publications in foreign countries—and it is dissected, compared, classified, and published, partly in the form of technical articles designed for the profession, and partly in the form of official circulars which are accompanied by memorandums setting out the general facts in language "understanded of the people," largely as material for local authorities by which they may instruct the public.

The conclusion at which I have arrived is that the best chance of reducing the mortality from cancer lies in two directions: first, the encouragement of research, and secondly, public education. I have not observed that uniformity of opinion is more general among doctors than among politicians, and I am quite aware that there are differences of opinion about the way to deal with cancer, but it is conclusively demonstrated by figures that cancer in its earlier stages is by no means an incurable disease, and that the chances of cure diminish rapidly if diagnosis and treatment are delayed. What I mean, therefore, by the education of the public is that the public should be enabled to recognize the symptoms which may be those of cancer, and having recognized them should lose no time in betaking themselves to consultation with those who can pronounce with greater certainty. We cannot in that way diminish the incidence of the disease, but we can increase the number of recoveries. I do not suppose that at any time there has been so large a number of skilled investigators at work upon this problem, and it is well to remember that all the great discoveries of the past have been merely the culminating point of a long series of investigations carried on by different people, in different places. It is a rash thing to prophesy, but I will venture to say that with the steady progress in research, with the attention which is being given to the subject in this and in all civilized countries, it is not unreasonable to hope that before another generation has passed the chief terrors of this nightmare will have been removed, and it is possible that cancer may be reduced to the category of those diseases of which man by his own efforts has made himself the master. (Applause.)

Questions and Discussion.

Sir Berkeley Moynihan then delivered his lecture, and at the close a brief period was allotted to questions. It was made plain that this was a lecture for a lay audience, and that any remarks from members of the audience should not be in the nature of expert discussion on causation, prognosis, or treatment. One gentleman in the gallery, whose remark was greeted with applause, complained that Sir Berkeley had urged them to go to the medical man on the first signs of cancer, but he had not told them how those signs could be recognized. Other questioners were eager to "draw" the lecturer on the subject of vegetarian diet. One gentleman wished to know why the mortality from cancer was three times as great among butchers, costermongers, and dock labourers as among clergymen, farm servants, and market gardeners. Others wanted Sir Berkeley to agree that there was an absence of cancer among primitive peoples, and that this was due to their simple life, or, again, that the cause of cancer was chronic constipation.

The lecturer, in reply, said that it was quite impossible at a meeting of that kind to describe the early symptoms of cancer as affecting different organs in men and women. In the Yorkshire campaign, in twenty-six towns, a place had been arranged to which people could go during one week in each and hear lectures and see demonstrations by a medical man or woman and be really instructed as to what these signs were; later it was proposed to take a motor caravan and tour the Yorkshire villages. But one thing might be said in a general way, that where there were lumps, ulcers, fissures that would not heal, the doctor should be seen without delay. There was no lump in the body which one could afford to ignore, especially if it was in the breast and in a woman over 35. As to diet, Professor Mellanby had been asked to make a new inquiry, and to see whether there was any possibility of a connexion between cancer and diet. At present there did not seem to be any such connexion. It had been stated that cancer

did not occur in tribes living away from civilization. He had always been sceptical as to the evidence in favour of that assertion, and Sir Leonard Rogers had stated that malignant tumours were about as common in Bengal as in England. One questioner had asked whether anxiety produced cancer. Anxiety, like other things, such as ill-regulated diet, absence of exercise, or vicious habits, undermined the health of the individual, and made him more likely to be the victim of cancer or of anything else that was going. "One speaker has said that he has a theory as to the cause of cancer. I have never met anybody in my life who had not! Cancer is a subject of such popular interest, and the minds of men are so constituted, that upon these topics, as upon political topics, they arrive at conclusions for which they have no evidence. We who, unfortunately, live with cancer cases are certain with absolute finality of some things, but with regard to others we realize that there is much to be discovered."

Some further discussion was then allowed, and gave an opportunity to dietetic enthusiasts, one of whom even implicated the breakfast rasher. Some of the speakers, each of whom was allowed three minutes, evidently had an animus against the surgeon's knife; on the other hand, two, who had been the subject of operations for cancer, one of them three years previously, spoke as to its benefit. The speakers, with one or two exceptions, were all lay people, but Dr. Louis Sambon said a few words, remarking that early surgical treatment was not only of the greatest importance from the remedial but also from the prophylactic point of view.

Votes of Thanks.

Sir ARTHUR SPURGEON (Chairman of the Public Health Committee, Surrey County Council) moved the vote of thanks to the lecturer, and expressed the hope that in the home counties there would be campaigns similar to that which Sir Berkeley Moynihan had led in Yorkshire. The resolution was seconded by Mr. F. BARRACLOUGH (President of the National Union of Teachers), and was accorded with long-continued applause.

Sir BERKELEY MOYNIHAN said that one of the speakers had probed the secret of his campaign. He had said that if such campaigns were successful he and other surgeons would have to "shut up shop." That was exactly what he (Sir Berkeley) wanted. A very large part of the livelihood he was able to earn he got from operating on cases of malignant disease, but he never knew a more miserable moment than when operating on a patient with regard to whom he had to say "Too late." Surgery could do great things if given a chance. He hoped the campaign would mean that the surgeon would have a better chance until the happy day came when his activities might be abolished. Within its first year nearly £150,000 had been contributed to the Yorkshire campaign, and the effect of the appeal was not finished yet. He himself knew the Yorkshireman better than most; he knew him inside and out—(laughter)—and he had succeeded in getting his hand very deeply into the Yorkshireman's pocket. He concluded with an expression of gratification that the Minister of Health, who on more than one occasion had shown great interest in the work of the profession, had been able to preside that evening.

Mr. R. G. HOGARTH moved a vote of thanks to Mr. Chamberlain. He said that the British Medical Association as far back as 1868 had declared itself in favour of the formation of a Ministry of Health, and for fifty years until that idea came to fruition pressed on successive Governments the urgency of that reform. That was all the more public-spirited of the Association because it must have been apparent that an efficient Minister of Health was bound to exercise powers which would impinge upon the unfettered activities of the profession. If some wondered why they were so quixotic it only showed the single-minded devotion of doctors to the public good. They realized how fortunate they had been since Mr. Chamberlain entered upon his office; they had to thank him for being an enthusiastic and earnest Minister; he had gone far to make up the great shortage of houses, and had carried on an unremitting campaign against the slum dwelling. He had on many occasions encouraged medical and scientific research. In the great campaign to improve the health of the people, which presented an ever-widening front as it moved forward, the office of the Minister of Health was undoubtedly the most important, and to have the power to attack in their fastnesses the ancient enemies of the public health must be one of the most desirable things to a statesman of ability and imagination such as the present Minister. The medical profession was glad to recognize in him an expert municipal administrator as well as a statesman of courage and resource. Also he had been a most courteous and understanding Minister in his relations with the doctors, who were his most indispensable, as they were his most loyal, associates in the supreme cause of public health. (Applause.)

Dr. MORTON MACKENZIE briefly seconded the vote of thanks, and expressed the feelings of the more than 30,000 general practitioners who constituted the British Medical Association in their pleasure at seeing the Minister in their own home.

This vote of thanks was also heartily accorded, and Mr. CHAMBERLAIN, in reply, mentioned that he was associated with the medical profession as a member of a hospital board long before he became Minister of Health, and he learned in those days to have the greatest admiration for the doctors, "coupled with a wholesome respect for their power of candid friendship." He had seen no reason to change that opinion since he occupied his present office, and he was proud of the support which had been given him by the profession in the endeavours he had made for the health of the community. He trusted that the present meeting, which had been very informative and successful, would be only the first in a widespread and vigorous campaign.

England and Wales.

PROPOSED ADVISORY EDUCATION COMMITTEE FOR SOUTH WALES.

AT a moment when the proposals of the Consultative Committee of the Board of Education for the reform of educational administrative areas and those of the British Medical Association for the reform of areas for health administration are, jointly or severally, exciting a good deal of discussion, it is interesting to note any practical action which is being taken for that co-operation in either of these spheres which is recognized as being the first step which can immediately be taken towards the ultimate and ideal unification of the administration of public health and education alike. It is not always easy to get self-contained authorities like county boroughs to realize that they have duties, moral if not legal, to their surrounding areas; nor to persuade a powerful county council that the non-county boroughs and urban districts within its area can help very materially in solving some of the most difficult problems of county administration. On the other hand, some examples of such co-operative arrangements made for the mutual benefit of a large number of local government areas are not far to seek. In the County Palatine of Lancaster, for instance, such arrangements have for some time been operative with regard both to tuberculosis and to mental disease and disorder. At a meeting this month of the Swansea Education Committee Dr. Arbour Stephens, the chairman, put forward a proposal for the establishment of a permanent advisory committee of the education authorities of South Wales and Monmouthshire to deal with all matters within their sphere in which co-operation was desirable. Such a scheme would, he contended, tend to weld the educational forces of South Wales into a coherent whole, as well as to relieve the ratepayers. The matters suggested as the field for such a committee were: arts and crafts, especially those of a rural nature, music, adult education, appointments and vocational selection, and especially the provision for the educational and other care of physically or mentally defective children. The Swansea Education Committee asked for a further development of the idea by Dr. Arbour Stephens, and decided to consider this carefully at its next meeting. There is no doubt

that several of the matters enumerated are of such a nature that they cannot be effectively or economically dealt with by small authorities or in sparsely populated areas, and the resources, financial and other, of all the local government authorities of a district, including county boroughs, are required to meet the needs. In quite a number of instances, as is suggested in South Wales, even the area of a county may be found far too small. Just at present, when there is, or should be, considerable development in the provision for mental defectives, for orthopaedic treatment, and for the care of children with rheumatic heart affections or chorea, proposals or experiments of the nature indicated are of much importance. Clearly something beyond advisory powers for such a joint committee may become necessary, but as an initial step the suggestions of Dr. Arbour Stephens may well be favourably regarded in the area affected.

CENTRAL MIDWIVES BOARD.

The report of the Central Midwives Board for the year ending March 31st, 1926, has been published by the Stationery Office at 6d. It shows a net increase of 2,889 midwives over the number appearing on the roll for the previous year. Of the 62,680 enrolled midwives, 44,777 have passed the Board's examination, 9,357 were admitted by reason of prior certification under Section 2 of the Midwives Act, 1902, and 612 midwives holding Scottish and Irish certificates are also included on the English roll. The trained midwives are consequently 54,746, as compared with 7,934 untrained, the percentage of the former having risen to 87.3 from 86.5 in the previous year. Of the 190 institutions and homes in England and Wales where midwives may be trained, 62 are Poor Law institutions. In addition to these institutions and homes, 64 practising midwives are approved as teachers, and 105 registered medical practitioners as lecturers. Private training accounts for the addition to the roll of 1,319 midwives practising in 1925, or 9.2 per cent. of all practising midwives. The number of candidates entering for examinations during the year was 3,922, an increase of 131 over the previous year, and of the 3,824 who completed the examinations, 3,008 were successful. In view of the lengthening of the training period it has been decided that, for the present, four annual examinations shall be held in place of the six arranged in previous years. During the year under review thirty-four midwives were dealt with by the Board under its penal powers, fourteen names being removed immediately from the roll; six women were censured, two cautioned; in two cases no action was taken by the Board; one midwife was suspended, and in nine instances sentence was postponed. A conference between members of the Board and representatives of local supervising authorities was held in March to consider various points arising out of the administration of the Midwives Acts and the interpretation of the rules of the Board. The Board ruled that midwives living in district nursing association homes were subject to the same rules as midwives in private practice, as regards investigations by the inspectors of local supervising authorities. In the opinion of the Board the professional association of a midwife with an unregistered medical practitioner is undesirable and might come within the meaning of the word "misconduct" in Rule D.1.

Scotland.

LISTER CENTENARY CELEBRATIONS AT EDINBURGH.

As already announced, the celebrations at Edinburgh of the centenary of Lord Lister's birth will be held in connexion with the Annual Meeting of the British Medical Association in July, 1927. A meeting will be held in the Macewen Hall of the University on the evening of Wednesday, July 20th, at which it is expected that Lord Balfour, the Chancellor of the University, will preside. Addresses will be delivered by Sir Watson Cheyne and Professor Tuffier of Paris, and it is hoped that Dr. Harvey Cushing of Boston may also be present. A collection of Lister relics will be shown in the Library Hall of the University; they are in part objects of permanent exhibition in this hall, bequeathed by Lord Lister to the University of Edinburgh, and in part are to be lent by the Wellcome Historical Medical Museum in London. A commemorative prize is being offered by the committee in charge of the celebrations, for competition by students, for the best essay on "The influence of Lister on surgical practice." As a permanent record of Lord Lister's connexion with Edinburgh memorial tablets are to be placed on the two houses inhabited by him at 11, Rutland Street, and 9, Charlotte Square, during his two periods of activity in Edinburgh. A memorial volume on Lister's work and Edinburgh connexions is in preparation; it will include a sketch of his life by Sir George Beatson, an outline of surgical practice prior to the advent of Lister's work by Mr. Alexander Miles, and a sketch of the work of Lister by Professor John Fraser. It will also include two of Lister's papers—his inaugural lecture on "Fermentation and putrefaction," and an address delivered by him to the British Medical Association at Edinburgh in 1875 on "The influence of antiseptics on the salubrity of hospitals." The book will include a series of short reminiscences by ten old students who had personal connexions with Lister as a teacher, and will contain some nine illustrations illustrative of Lister's Edinburgh period.

THE BRITISH FLORA.

A lecture delivered in the hall of the Royal Botanic Garden at Edinburgh by Mr. J. R. Matthews, lecturer on botany in the University, was the first of a series of public lectures to be held under the auspices of the Botanical Society of Edinburgh. Mr. Matthews's subject was "The story of the British flora," and he pointed out that there were three distinct elements in the flora of Great Britain. He showed by maps and lantern slides that over one hundred plants found in the Highlands of Scotland and in the mountains of England and Wales constituted a boreal element closely related to the present flora of Scandinavia. The southern type was confined to the southern counties of England and Ireland, although some of these extended along the western coasts to a northern part of Scotland. On the Continent the same species were found only along the Atlantic coasts of France and Spain and on the shores of the Mediterranean. The third was the Germanic type, which formed the main part of the common and widely distributed plants of Britain, and was well represented in the flora of Central Europe. After discussing the origin and history of these three types of native flora Mr. Matthews expressed the opinion that the present range was apparently the result of past climatic changes. The presence of the boreal species in the Highlands of Scotland was attributable to the great Ice Age, and the same plants in glacial times were known to have inhabited the South of England also.

RESCUE WORK IN MINES.

A lecture on mine rescue appliances was delivered at the Heriot-Watt College, Edinburgh, on January 15th by Professor Henry Briggs, who said that some years ago he had made a series of experiments to ascertain the most economical speed for men walking on the flat and carrying a load of 40 lb. In most cases it was found to be about three miles an hour, or if the going was rough, as upon an underground road, two and a half miles an hour was the most economical rate in food supply and oxygen for the average person. This, he said, was important to wearers of rescue apparatus, who carried with them the means of supporting respiration, because at the most economical rate the caustic soda cartridge by which the carbon dioxide of the breath was removed underwent a minimum amount of exhaustion. The lecturer described a number of modern self-contained forms of apparatus fed with oxygen from a highly compressed supply carried in small cylinders. The earliest of these had been the Fleuss or Proto apparatus, invented by Mr. Henry Fleuss in the seventies of last century and used in 1880 at a fire in Seaham Colliery, Durham; it had had a remarkable record of successful work, particularly in the recovery of miners in Staffordshire after explosions, and on the Western front during the trench warfare period. The apparatus was used, for

example, after the Redding Colliery disaster in 1923. Professor Briggs also referred to the apparatus which had been introduced by himself and used at the Whitehaven disaster in 1921, as well as in numerous places overseas. This had been reported by two committees to be the most suitable type for India, and had taken first place in a competition held in Nova Scotia between British and American apparatus.

Glasgow Students and Hospital Collections.

For some years Glasgow students have held a Charities Day collection, chiefly in aid of the hospitals of the city. This year the collection took place on Saturday, January 15th, with an unusually great measure of success. Over £14,300 in all was collected during the day. Special prominence had been given to the effort by an attempt made by the Local Trades and Labour Council, who, feeling sore over the fact that students had taken the place of various workers during the general strike last year, decided to retaliate by proclaiming a workers' boycott of the Charities Day. This stirred up so much adverse public opinion that the great success of the collection may in all probability be largely attributed to the attempted boycott. Some 7,500 students were engaged in the collection, including students of the various faculties in the University, veterinary students, engineering students, and others. The operations for the day commenced with early morning raids by collectors on tramway cars and other vehicles in the streets. In the forenoon the collectors were organized into a procession, which set out from the University for George Square in the centre of the city. The procession was headed by a pipe band of pantomime Highlanders, and consisted of some 150 lorries showing various tableaux. A message was issued by the Lord Provost commending the students' effort, and a collection in the streets and from door to door proceeded throughout the day. The sale of immunity badges realized £2,150. The sum collected in the present year is larger by nearly £5,000 than in 1926.

Annual Health Report for Edinburgh.

The report on the health of the city of Edinburgh for 1926 by Dr. Robertson, medical officer of health for the city, was submitted to the Public Health Committee on January 18th. The general death rate, 13.5 per 1,000 of the estimated population, was the lowest recorded since the extension of the city boundaries, and compared favourably with the figure for the preceding year, which had been 14.5. The tuberculosis death rate was 0.9, which was lower than that of either 1925 or 1924. The deaths from measles and whooping-cough were 85 fewer in 1926 than in 1925. The infantile mortality figures were also favourable, the rate having been 80 per 1,000 of the estimated births in 1926, as compared with 96 in 1925. There had been 377 fewer cases of diphtheria and 527 fewer of scarlet fever than had been notified in the previous year. The report concluded with a suggestion that a health exhibition should be promoted by the corporation in the early part of 1928, and that to widen interest in it the co-operation of the education authority as well as of other municipal bodies should be obtained in order to make a display which should be interesting to the public and of educational value. The committee approved of the principle of holding such an exhibition.

Royal College of Physicians of Edinburgh.

The annual dinner of the Royal College of Physicians of Edinburgh was held in the Hall of the College on January 14th. Professor George M. Robertson, President of the College, occupied the chair. The toast of "The Secretary of State for Scotland" was proposed by Sir Robert Philip, Vice-President of the College, and acknowledged by the Right Hon. Sir John Gilmour, D.S.O. The health of "The Guests" was proposed by Dr. Robert A. Fleming, Acting Treasurer of the College, and replies were made by the Very Rev. C. L. Warr, Dean of the Thistle, by Mr. Condie Sandeman, K.C., Dean of the Faculty, and by Sir H. Arthur Rose, D.S.O., chairman of the General Board of Control. "The Royal College of Physicians and its President" was submitted by the Right Hon. Hugh P. Macmillan, K.C., and duly acknowledged by the chairman.

Municipal Medical Officers as Town Councillors.

At a meeting of the Lower Ward Committee of Lanarkshire held at Glasgow on December 9th last the question was considered whether a doctor employed as the executive medical officer of the Joint Venereal Diseases Committee who had been elected a member of the Glasgow Town Council at the November election should hold both positions. The medical officer had communicated to a general meeting of the committee his intention of accepting nomination as a candidate for the Glasgow Town Council, and had stated that if he should be elected his services as a councillor would not interfere with the discharge of his duties as executive medical officer of the Joint Committee. The committee expressed the opinion that it would be inexpedient for him to accept election to a public body such as he proposed. A subcommittee was appointed on November 10th last to consider the whole circumstances of the case. The Lanarkshire County Council had the report before it on January 19th, when it agreed that the medical officer must give up his seat on Glasgow Town Council if he desired to continue in their employment.

Ireland.

Public Health Reforms in the Free State.

Public health administration in the Irish Free State is undergoing complete reorganization, and it is hoped that, when the clauses of the Local Government Act of 1925 which deal with this matter have been put into force, there will be a steady improvement in the health of the people. Chief among the provisions of that Act is the appointment in every county, or health unit, of a full-time medical officer, who will supervise the entire health administration of his area, including the medical and dental inspection and treatment of school children. The cost of the reorganized system to the ratepayers will be small, and the Department of Local Government feels that it will be productive expenditure in the best possible sense. In communications to the press Mr. E. P. McCarron, secretary, and Dr. E. F. Stephenson, chief medical officer of the Department of Local Government and Public Health, have made the following statements:

Our public health organization is definitely behind modern requirements, owing largely to the fact that our expert local health officers were primarily employed in treating disease. Heretofore sanitary defects were taken as a matter of course, but with the establishment of the Free State a more searching criticism, from sources both internal and external, has been applied. The rapid progress in health legislation, and especially as regards the protection of food, made in England, Denmark, and other countries, has placed us at some commercial disadvantage, and it is feared that, unless strenuous efforts are made to make good our recognized defects, Irish products in competition with those where hygienic methods are systematically adopted will be prejudically affected, or the markets may be closed on health grounds. It is felt that highly qualified and experienced men are essential to undertake these important health problems and to bring the sanitary requirements to a proper standard. Apart from the public health point of view, which is of the utmost importance, the trade aspect of the question is being daily pressed on the Department. In consequence of representations made to the authorities in the United States, Dr. Tuck, inspector of the Bureau of Animal Industry, was specially detailed to visit this country and report on the conditions under which bacon was prepared for export. Recent proceedings of the British House of Parliament show that a critical watch is being kept on the admission of Irish milk and cream, and uneasiness by leaders of the dairy industry is felt.

The main essentials in public health administration are: (1) sanitary areas of adequate extent, and (2) trained whole-time health officers to control the sanitary inspectors and to administer the laws and regulations impartially. Infection and disease have little relation to arbitrary administrative boundaries, and it is beyond dispute that the best results in the prevention of human suffering and death are achieved in large areas of local control. Experience has shown that, however competent a part-time medical practitioner may personally be, he frequently suffers from certain unavoidable disabilities in his capacity as a medical officer of health. He is individualistic rather than communal in outlook, and his public duties conflict with his interest as a private practitioner, and often bring him into

collision with his fellow practitioners. These two essentials were recognized in the Local Government Act, 1925, and the appointment of whole-time medical officers of health is now not alone a statutory obligation, but is an inevitable corollary to the widening of the administrative area which was accomplished under the provision of that Act. Few reforms have received so much public consideration prior to being embodied in legislation as that of the whole-time medical officer of health. It was recommended by the Irish Public Health Council in May, 1920. Later, in 1923, the whole subject was carefully considered by the General Council of County Councils, who, when local rates generally were at a point higher than at present, proposed the county councils as the appropriate health units, and as regards staffing made the following recommendation. We recommend:

(*a*) That the following health officers should be appointed for each health unit (with assistants, where necessary) under a scheme to be approved of by the Minister of Local Government: (1) a whole-time medical officer of health; (2) a whole-time veterinary officer of health (all veterinary inspection to be carried out by whole-time veterinary officers); (3) provision should be made for the effective medical examination of school children and of the conditions, from a health point of view, under which they receive instruction.

(*b*) That the qualifications of all candidates for surgical, medical, and veterinary appointments by local health authorities and Poor Law authorities be in accordance with regulations to be made by the Minister of Local Government, and that such regulations shall include competitive examinations, practical as far as possible.

A failure to carry out the express requirements of the Local Government Act would lead to administrative confusion, would place the country in a hopelessly backward condition when compared with health reforms undertaken elsewhere, and would leave the health of the people a plaything to infection. The danger arising from neglect of public health administration is all the more serious owing to the facilities now existing for the rapid transportation of human beings, who are the chief carriers of infection. Infection, uncontrolled, results in widespread disease, suffering, disablement, and death, and imposes a heavy burden on the rate-paying public. The detection of the earliest cases of the most common infectious diseases and the adoption of measures to prevent their transmission would save thousands of pounds annually. Diphtheria, which is being eradicated in other countries, is endemic in many districts in An Saorstat, and demands a heavy toll in mortality and rates. Polluted water taken by a common carrier in one county might lead to outbreaks of disease in any number of other counties.

Among the duties of the county medical officers of health, as set out in a recent Local Government Department Order, are:

The effective administration of the sanitary laws, and the safeguarding of the health of the people in respect of housing and other matters.

Inquiry into the origin, causes, and distribution of disease. Periodical inspection of districts.

Taking steps to deal with infectious or epidemic disease.

Direct and superintendent medical officers of health.

Inspection of food, slaughterhouses, dairies, cowsheds, and milkshops.

Supervision of the health of expectant and nursing mothers, and children under 5 years. Supervision of the welfare of blind persons. Arrangements for school medical inspection.

Correspondence.

SYSTEMIC TREATMENT OF CANCER.

SIR,—In your issue of December 11th, 1926 (p. 1135), in an article by R. G. Canti, M.D., entitled "Lead treatment of cancer: an account of a demonstration by the Liverpool Medical Research Organization," the author, in the first paragraph of his conclusions, states as follows:

"Remarkable and impressive as are certain of the cases in which lead alone has been used, it cannot be too emphatically stated that the importance of the research being carried out at Liverpool lies, not in the wonderful individual results obtained (which form only a small percentage of the cases treated), but in the fact that it is the first time in history that a generalized treatment has been found that brings about a local disappearance of a cancerous growth."

I believe that Dr. Canti must have overlooked or forgotten the very considerable number of inoperable malignant tumours of all types that have been reported in medical literature by competent observers, which have disappeared as a result of an attack of erysipelas either occurring accidentally in the course of the disease, or produced by inoculation as a method of treatment. Inasmuch as in most of the reported cases the area affected by the erysipelas was remote from the site of the malignant tumour, one must conclude that the tumour disappeared as a result of the *systemic* action of the streptococcus rather than any local action.

An objection might be raised to regarding these cases of accidental erysipelas as a method of treatment, but this would not apply to the cases of inoperable malignant tumours treated by inoculations of the living cultures of the streptococcus, in which the erysipelas was produced deliberately as a definite method of treatment, based on the results observed following accidental erysipelas. Much less would this objection apply to the results obtained by the use of the toxins of the streptococcus alone or combined with the toxins of *Bacillus prodigiosus*, which was the next step in the evolution of a method of treatment based upon the authentic and indisputable evidence that the streptococcus of erysipelas in the form of a localized attack of erysipelas has a powerful influence upon malignant tumours of all types, even far remote tumours, which influence in a considerable number of cases has been sufficient to cause the complete disappearance of such tumours and to result in a permanent cure of the patient.

In my paper on the treatment of malignant tumours by repeated inoculations of erysipelas, with a report of ten original cases (*American Journal of the Medical Sciences*, May, 1893), I collected from literature 38 cases of malignant disease in which erysipelas had occurred by accident or design. In 23 cases the erysipelas occurred accidentally, and in 15 it was the result of inoculation. This series included 17 cases of carcinoma, 17 cases of sarcoma, and 4 cases of either sarcoma or carcinoma. In the group of carcinoma 3 were permanently cured, 1 was well five years later, and in 10 of the remaining number decided improvement was noted. In the group of sarcoma 7 were alive and free from recurrence from one to seven years after the attack of erysipelas.

Eschweiler, in a monograph published some years later, collected from literature 69 cases of accidental erysipelas associated with malignant tumours; 27 of these were sarcoma, 38 were carcinoma, and in 4 cases the type of tumour was undetermined. In the group of sarcoma 7 showed temporary improvement, in 10 cases the tumour entirely disappeared (one later recurred), there were 9 apparent cures, and in 4 cases the patient remained alive and well from two to eight years. In the group of carcinoma 12 showed improvement, in 8 cases the tumour entirely disappeared (in 3 the disease later recurred), there was no apparent effect in 9 cases, and in 6 cases the patient died of the attack of erysipelas.

In January, 1893, in order to eliminate the risk attached to the use of the living germs, and to overcome the difficulties encountered in trying to produce the desired attack of erysipelas, I began using the toxic products of the streptococcus of erysipelas, or the killed cultures, at first alone, and shortly afterwards combined with the cultures of the *Bacillus prodigiosus*. It is impossible in the short space permitted in your correspondence columns to refer more than briefly to the later developments of the method and the results obtained. It is important, however, to note that in a very considerable number of cases of inoperable malignant tumours, chiefly sarcoma but including all types of malignant tumours, these tumours have been caused to disappear entirely by injections of the mixed toxins of erysipelas and *Bacillus prodigiosus*. Reports of these cases have been published from time to time in the leading medical journals of America. In 1909, in a paper read before the Royal Society of Medicine, London, the method was fully described and the results given. This paper was published in the *Proceedings of the Royal Society of Medicine*, November, 1909, and a full abstract appeared in the London *Lancet*.

The most complete report of the end-results appeared in a paper entitled: "The treatment of malignant inoperable tumours with the mixed toxins of erysipelas and *Bacillus prodigiosus*; with a brief report of 80 cases successfully treated with the toxins from 1893 to 1914" (read before the Third International Conference of Cancer Research, Brussels, August 1st to 5th, 1915). This paper was too long (175 pages) to publish in the medical journals, but it will soon appear in book form with additional cases treated since 1914 and the end-results to date. The successful results obtained in the 80 cases referred to followed the use of the method in a series of 710 cases; in other words, the proportion of successes observed was a little over 10 per cent. In the great majority of cases in which the tumour disappeared under the toxin treatment the cure has remained permanent; fifty-nine of the

patients were alive and well from three to twenty years. These were practicably all inoperable, hopeless cases; and it is important to note that nearly all of them were treated by toxins alone without the aid of *x* rays or radium. In addition, this paper contains a report of 125 cases successfully treated by other men, some of the latter being English surgeons. A brief report of these may be of interest.

An inoperable spindle-cell sarcoma of the abdominal wall treated by Major C. G. Spencer of the Royal Army Medical Corps was well six years later.

A periosteal spindle-cell sarcoma of the ramus of the lower jaw treated by Dr. Frank Kidd of London was well four years later.

A sarcoma of the femur treated by Dr. Deanesly (see BRITISH MEDICAL JOURNAL, May 28th, 1910) was well fourteen years later.

A recurrent inoperable melanotic sarcoma of the neck treated by Dr. H. H. Greenwood of Leeds was well twelve years later.

A far advanced typical Hodgkin's disease treated by Dr. C. E. Preston of Ottawa, Canada, was well eleven years later.

An inoperable recurrent hypernephroma of the kidney treated by Dr. Arthur Connel of the University of Sheffield was well eleven years later.

In a recent follow-up of ninety-three cases of inoperable sarcoma treated with the toxins alone (reported before the Johns Hopkins Medical Society in 1896) I find sixteen patients have remained alive and well from eight to thirty-three years, and twelve from ten to thirty-three years.

It is interesting to note that the dangers associated with this method of treatment—namely, by the mixed toxins, are practically *nil*; I have observed only three deaths in one thousand cases. In addition to cases of inoperable sarcoma successfully treated, a number of inoperable carcinomas have entirely disappeared, the patients remaining well for many years; and also several cases of melanoma—a type of tumour rarely cured by surgery and extremely resistant to both *x* rays and radium—have recovered and remained permanently well.

This letter is written with no idea of detracting from the value of the splendid research work that is being carried out by Professor Blair Bell and his co-workers in Liverpool; but merely to correct the statement of Dr. Canti that the lead treatment is the only systemic method of treatment that has ever caused the disappearance of a malignant tumour. Professor Blair Bell has undoubtedly accomplished a brilliant piece of work; and we are hoping that further investigations will show the possibility of eliminating the risks associated with the treatment, thus adding to the value of the method. There is no question but that we have nearly reached the limit of our ability to control cancer by local methods—that is, surgery and radiation. In spite of the great advances in the perfecting of these methods of treatment, cancer mortality is steadily increasing, and any hope of really controlling the disease must lie along the lines of systemic treatment. The problem of the control of cancer is so great that *I believe all new* research work in every direction should be given every possible encouragement. At the same time, we should not permit our enthusiasm over the new to make us forgetful of what has been accomplished by the older methods.—I am, etc.,

New York, Jan. 3rd. WILLIAM B. COLEY, M.D.

MONGOLIAN DEFECTIVES.

SIR,—I do not undervalue the importance of Dr. Cock's letter on page 120 of your issue for January 15th. But I do not agree that "an organized being *cannot* be a descendant of another whose development is in an inverse order to its own" in respect of such details as those adduced by Dr. Cock. So much, to me at least, is *not* "evident," and zoology teaches us that alternate generations may do some very queer things. Still, if Dr. Cock's view is correct, it does not follow that "man *cannot* be considered as the descendant of *any* simian type." It is quite easy, for the Darwinians have never produced man's hypothetical ape-man ancestor. All that is necessary is to *assume* that this ape-man really did develop in the same order as we do. Why not? I do, however, willingly admit that those who lay it down as an article of faith that the development of the individual man recapitulates, without serial dislocation, the order of development of the race, must be embarrassed by such facts as are brought forward by Dr. Cock; if, that is, they postulate for man ancestors who developed in the order that Dr. Cock says obtains amongst certain apes and not amongst man.

But the many kind critics of my little book who, not having read it, yet criticize it, do not seem quite clear about the views therein expressed. Ever since being an asylum medical officer—now thirty years ago—I have been interested in the homologies that do obtain between Mongolian defectives, Mongoloids who are not defective, orangs, and racial Mongols. These homologies, which have lately been shown (1) by Kurz to extend to the intricacies of the cerebral development of orangs and racial Mongols, and (2) by Gans to the cerebral morphology of Mongolian defectives and racial Mongols, as fourteen years ago I predicted would be the case, cannot, it seems to me, be easily dismissed as "superficial" in the fashion of the author cited by Sir John Lynn-Thomas in the BRITISH MEDICAL JOURNAL for January 15th (p. 94)—unless, that is, good reason is given *why* they should be so dubbed. However, though I am only secondarily interested in the "explanations" of these homologies, it does seem to me that if, as good Darwinians insist, "homologies prove descent"—the assumption underlying the culture-diffusion hypothesis of Professor Elliot Smith—then, unless these homologies be disposed of as "superficial," we are compelled away from strict monogeny and towards some polyphyletic theory of man's descent. Or, alternatively, we can abandon the major premise. Such is the very interesting position now reached—a position worth exploration. And I cannot for the life of me understand why Dr. Clarkson should imply (BRITISH MEDICAL JOURNAL, January 1st, p. 42) that there is any antagonism between an "atavistic" and a "pathological" explanation of the morphological characters of any individual. Nor can I see how anyone can roundly assert of certain morphological characters (as does a commentator in the *Lancet* for December 25th, 1926, on page 1332) that such "are not racial characteristics but pathological stigmata." Why not both? I have always thought—innocently—that while anthropology could discover and tell us much about many homologies, human medicine and pathology—which are but parts of anthropology—might be able to tell us how and why only some of the children who are, so to speak, anthropologically eligible for Mongolism should remain during life as Mongolian defectives or more *intelligent* Mongoloids. The commentator in the *Lancet* says that *every one* of the characteristics of the Mongolian defective marks him as "half-baked." This is to admit their reversionary significance, is it not? Yet, almost immediately, the same writer insists that these signs of "half-baking" are pathological, and not atavistic or racial! Why, then, are *not all* "*half-baked*" children—the phraseology is, I suppose, pathological—Mongolian defectives?

I am certain that no one who has weighed the anthropological issues shares the fears of Dr. Clarkson that, in his so doing, there may be lurking a tendency "to stifle" pathological or physiological research, which *may* be likely, as Dr. Clarkson says, to lead us one day to the truth, but which certainly is long about it. On the other hand, if I may say so with the utmost good humour, no one knows better than I the amusing, quite successful, and very persistent efforts made by pathologists and clinicians, during fourteen or fifteen years, "to stifle" discussion of the anthropological issues. That is why I was compelled—or impelled—to write my little book for a non-medical public! Yet the occurrence amongst us of Mongoloids—not merely of such Mongoloids, dully "normal" in their intelligence, as Dr. Clarkson tells us he has never seen, but so remarkable as the still living statesman who guided the fortunes of France to victory, and the seaman who presided for a time so brilliantly over our sea destinies during the great war—forbids us to narrow the question of Occidental Mongolism down to the petty one of a few imbeciles in workhouses and asylums. And so it is that Aleš Hrdlička,

in his latest work *The Old Americans*, admits the occurrence of Mongoloids, in Germany and "even in England," as a fact susceptible of ethnological explanation. But to reply to all the points raised now by Dr. Clarkson would divert attention from that which was the subject of my letter in your columns for December 4th, 1926 (p. 1080): the fallacy of an "argument" which may be generalized as declaring an atavistic explanation of homologies, between a living individual and (1) a hypothetical ancestor or ancestral group, or (2) an existing group to which he is not known to be related, to be "negatived" unless complete physical and mental resemblance can be (*a*) postulated in respect of the hypothetical ancestry, and/or (*b*) demonstrated in respect of the living individuals whom he resembles, and with whom he shares the completely resemblant though hypothetical ancestry. Such an "argument"—which is dogmatic assertion and not argument—appears to have been unfortunately used by Marfan of Paris in a recent lecture, where—again unfortunately—it is clear that there was no first-hand knowledge of the work of English physicians. This argument is reproduced, with apparent gravity, in the *Lancet* (loc. cit., vide supra), wherein W. J. Langdon-Down is said to have suggested Mongolism to be a reversion to a remote ancestral type, and where the "standing argument" against this view is said to be that if Mongols (? Mongolian defectives) are really throw-backs to Mongolian ancestors (which no one, I think, really suggests), then they (the "Mongols") ought to be physically and mentally as fit as are normal Chinese or Japanese. But why "ought"?

Brief consideration convinces most people that if this "standing argument" is left standing, no idiot "ought" to resemble his grandfather unless each of them is as imbecile as the other and as normal as are the cousins who "take after" the old gentleman. Nay; all evolutionary theory explodes—and here Dr. Cock will support me—for in a world wherein everyone completely resembles his ancestors and his collaterals there must be an end of evolution and "reversion" alike. But it would then be equally impossible for the sons of Ham to claim consinship with the sons of Shem and of Japheth, *and* common descent from Noah—that is, if Professor Marfan, Dr. Clarkson, and the *Lancet* are to be believed.

In conclusion, I would refer any of your readers who, with Dr. Clarkson, may fear that I have too freely translated Gans's work, to para. 510 in the *Epitome* of the BRITISH MEDICAL JOURNAL for 1925, vol. ii. Those who wish acquaintance with the work of Kurž should first read his brief summary in *Anatomischer Anzeiger*, 58 Band, 1924, and afterwards his longer and illustrated memoirs, most of which appeared in *Zeitschrift fur Anatomie* during 1922, 1923, and 1924. The bearing of Sera's work (as Jack Bunsby might have said) lies in the application of it. When we know that things which are equal to the same thing are equal to each other we make real progress in the synthesis of knowledge.

But, after all, the first question is whether or no the homologies in question are to be observed. It is not well to pretend they do not exist, or to declare that they are superficial, just because they are inconvenient, or inconsistent with current orthodoxies. On the other hand, no one conversant with modern trends worries very much about the real or historical truth of Darwinian or other theories as to the *origin of man*. Such theories and hypotheses are useful, in a book-keeping kind of way, as convenient summaries of what we think we know. Personally, I am never afraid of any hypothesis or inference from observed facts so long as it is logically legitimate and practically profitable, and until another emerges that has a better title on either or both of these grounds.

I regret, Sir, the unconscionable length of this letter, but if I can only induce my critics to read my little book I will have no occasion, I hope, to trespass again upon your indulgence. Can we not all agree to continue our observations and not to indulge in "standing arguments" that have no logical or pragmatic justification?—I am, etc.,

London, W.1, Jan. 20th. F. G. CROOKSHANK.

DELAY IN REGISTRATION AFTER PASSING QUALIFYING EXAMINATION.

SIR,—On December 7th last the pass list of the London M.B., B.S. was published. On December 8th the fee for registration was forwarded to the General Medical Council by a newly fledged graduate. The receipt for the fee was received within a few days.

Naturally, as opportunity arose, medical work was undertaken by the junior.

On January 16th this practitioner went to a case of apoplexy. The patient, who had been under the observation of a senior practitioner for several months, but had not been seen recently by him, died within an hour of being visited by the junior on behalf of the senior. To make sure of being a registered practitioner the junior inquired at the office of the General Medical Council as to being able to sign the death certificate. The reply obtained was that the junior would not be registered until January 26th—that is, seven weeks after the publication of the lists and after complying with what was required.

It is stated that the delay is due to the London University not sending the necessary information to the General Medical Council.

This involved application to the coroner for leave to give a certificate by the senior and led to delay in granting the certificate to the relatives. Surely, Sir, this ought not so to be.—I am, etc.,

January 17th. SENIOR.

*** The facts stated by "Senior" certainly seem to involve a distinct hardship, and as the practice of the University of London was not within our knowledge we communicated with the Registrar of the General Medical Council, who informs us that the Council cannot register *on the strength of a pass list, but must wait until the* diploma (in this case the degree) has actually been conferred. We understand that the attention of the University has been repeatedly called to the matter, but that its practice has not been modified. Some delay is no doubt inevitable, but seven weeks would appear to be an unduly long time. It seems to be a matter to which the authorities of the University should give attention.

METHOD OF TREATING ASTHMA BY RADIATION.

SIR,—Several radiologists who have tried the method for treatment of asthma by radiation described in the preliminary note published in the BRITISH MEDICAL JOURNAL of June 5th, 1926 (p. 939), have sent me particulars of certain cases so treated and of their results.

While I have no doubt as to the beneficial effect of general radiation in bad cases of long standing, there are several interesting phenomena on which further evidence is required. I should be much obliged to those radiologists who have tried the method if they would let me have details of the cases they have so treated, the results obtained, and any phenomena that they have noticed during or after the treatment; such details may be sent to me at the Radiological Institute, 32, Welbeck Street, W.1.—I am, etc.,

London, W.1, Jan. 24th. S. GILBERT SCOTT.

THE FOETAL THYROID GLAND.

SIR,—The conclusions at which Dr. Ian Murray arrives in his paper on the thyroid gland of the foetus and newly born (January 1st, p. 5), as to the effect of *post-mortem* changes on the appearances of the colloid and the vesicles, confirm the observations published by Professor Lucas Keene and myself (*Lancet*, July 19th, 1924). We suggested then that the *post-mortem* changes found in apparently fresh thyroid material might be due either to a maternal toxaemia or to extreme congestion of the foetus caused by prolonged labour: in both cases an unstable condition of the foetal thyroid would be induced, and any *post-mortem* change consequently accelerated. The appearance of vacuoles in the colloid varies greatly with different animals when the material is fixed in a fresh condition; for example, an actively secreting rat's gland usually shows

these vacuoles, whereas they are absent in the resting vesicles (see also McCarrison, *The Thyroid Gland*, 1917); in man the material obtained at operation and fixed at once rarely shows vacuoles in the colloid. As an extension of our work on the human foetus special histological examination of thyroid glands has been made, from which it would appear that the staining reaction of the colloid varies greatly with the state of activity of the gland, and that there is a correlation between the *p*H of the colloid and the secretory activity of the vesicular cells. It is hoped that these observations will shortly be completed for publication.—I am, etc.,

London, W.C.1, Jan. 18th. E. E. HEWER, D.Sc.

LAW AND TRADITION OF MEDICAL PRACTICE.

SIR,—In your recent reference to our book *An Introduction to the Law and Tradition of Medical Practice*, which makes no pretence to be more than an introduction to a complete work, you take exception to our views on two or three points of professional etiquette.

You challenge our contention that it is regarded as advertisement for a practitioner to send signed articles or letters to the lay press. It is, however, common knowledge that the practice has led to names being struck off the *Register*, though exceptions have been made in certain cases by the General Medical Council. We pointed out that these exceptions are made without reason stated and without the disclosure of any principle as a basis for them. The recent publication of certain famous articles with the apparent approval of the General Medical Council appears to us to be on all fours with other cases in which members of the profession have been penalized under the heaviest sanction which the General Medical Council can enforce. *Unless it can be shown that the exceptions are based on* a recognized principle, they must tend to discredit the authority of the governing body of the profession.

With regard to tradition generally, it is always difficult to decide the exact time when an unwritten code has grown to the point when it is so generally accepted that it may be reduced to writing and regarded as authoritative. In our book we have not ventured beyond the point where medical men have themselves written on the subject. For instance, you criticize us for saying that it is a breach of etiquette to inform the patient of the disagreement of consultants. In at least one of the older authorities this is laid down without qualification. While we are willing to admit that some modification of the statement may be desirable, the informing of a patient is obviously a matter which must be dealt with with such extreme caution as to warrant a textbook writer drawing attention to it.

It may be that after consulting medical men we took a small step beyond the other textbooks in condemning the employment of unqualified dispensers in all cases. As far as the scheduled poisons are concerned we were on safe ground, and the General Medical Council has laid it down that to employ unqualified dispensers will be treated as infamous conduct in a professional respect. As to the employment of unqualified practising chemists there can be no question that this is contrary to professional etiquette in the same way as co-operating with unqualified dentists, because under the Pharmacy Act a chemist is bound to be qualified. We contend that the employment of unqualified dispensers is contrary to the best traditions of the profession and is a transgression of the spirit of the law.

We have to thank you for your valuable notice and for the opportunity you have given us of correcting several errors in our book.—We are, etc.,

WILLIAM SANDERSON,
Lincoln's Inn, Jan. 20th. E. B. A. RAYNER.

*** By their rejoinder Messrs. Sanderson and Rayner strongly confirm our original judgement that their didactic enterprise has been undertaken with a quite inadequate equipment. They state four propositions, and each of these announces unfamiliarity with medical custom and tradition, and some of them also ignorance or misconstruction of the written word. We will discuss these propositions in detail, as they express misconceptions not infrequent in non-medical circles.

1. It is not true, as the writers allege, that "to send signed articles or letters to the lay press" is condemned by the General Medical Council. What the Council forbids to the practitioner is "advertising, whether directly or indirectly, *for the purpose of obtaining patients or promoting his own professional advantage*," and it is only on proof of one or other of the ambitions indicated in the phrases here placed in italics that an offender will be punished by the Council. Messrs. Sanderson and Rayner would have been spared this blunder if, instead of adopting the ingenuous conclusion that one signed medical article is "on all fours with" all other signed medical articles, they had read the official "Notice" of the Council.

2. It is both incorrect and absurd to affirm that "certain famous articles" in the lay press have the "apparent approval" of the General Medical Council. Such a statement can proceed only from ignorance of the Council's powers and responsibilities in its action as a judicial body. Messrs. Sanderson and Rayner will doubtless allow that in the ordinary affairs of life many illegal and improper actions escape all legal penalty because, either the law does not cover them, or the offended person will not complain, or the available evidence is not adequate. It would scarcely be correct to say that these actions enjoy the "apparent approval" of the High Court of Justice.

3. Reinforced by some unnamed medical writers, and by "at least one of the older authorities," our barrister authors continue to find attraction in the doctrine that "it is a breach of etiquette" to inform the patient that doctors who have met in consultation on his case cannot agree. We will offer them the opportunity of a practical problem: Dr. A. says the leg must be cut off; Dr. B. says it must be left on. What in these circumstances is to happen (i) to medical etiquette, (ii) to the debatable leg? The truth, of course, is that when differences of opinion concern practical action they must be revealed, while mere academic debate and discussion remain naturally within the consulting-room. Every writer we know accepts this conclusion; and inevitably, for it is imposed by the logic of events. Messrs. Sanderson and Rayner protest their right to draw attention to the subject. Admitted—provided they first take pains to save themselves from elementary blunders.

4. Meeting our denial of their affirmation that doctors "must not employ unqualified dispensers," the authors write: "As far as the scheduled poisons are concerned we were on safe ground, and the General Medical Council has laid it down that to employ unqualified dispensers will be treated as infamous conduct in a professional respect." If this proposition is true every medical practitioner—and they are to be numbered by thousands—who employs a dispenser not qualified under the Pharmacy Acts, and allows such dispenser to make up any medicine containing one or other of the substances scheduled in these Acts as "poisons," runs the risk of removal from the *Medical Register*. But the proposition is not true. The General Medical Council has not laid down what it is here alleged to have laid down. What it has laid down is that condemnation will fall on any practitioner (a rare bird) who keeps "an open shop" in which scheduled poisons are sold to the public and employs for this purpose a person not legally qualified to sell scheduled poisons. But a practitioner who does not keep "an open shop" is at liberty either to dispense his own medicines or to employ for this purpose any person deemed by him to be competent for this duty. Messrs. Sanderson and Rayner condemn this practice as "contrary to the best traditions of the profession." Their capacity to define these traditions has so far remained latent; and custom, widespread and of long standing, denies their thesis. They say also that this custom is "a transgression of the spirit of the law," and here they go a little too far. Barristers may, with some show of reason, tell us what is "the law"; but "the spirit of the law" is for philosophers, and to this character our authors will hardly pretend.

The true story of the General Medical Council's condemnation as mentioned above is as follows: Under the Pharmacy Acts no person may keep open shop for the sale or dispensing of the scheduled "poisons" unless he holds a qualification granted after examination by the Pharmaceutical Society. The Act, however, does not apply to

qualified medical practitioners, any one of whom therefore may, if he so wills, keep open shop for the above mentioned purposes. In rare instances doctors have exercised this right, and have sold scheduled poisons across the counter. Next, certain doctors claimed the right to leave in charge of the "open shop" a person qualified neither in medicine nor in pharmacy, on the view that when a "poison" was "sold" the legal "seller" was the legally qualified doctor who owned the "shop," and not the unqualified assistant who delivered the goods. By a judicial decision, however, it was decreed that legally the "seller" of a "poison" is the individual who conducts the sale across the counter and hands the substance to the purchaser. Therefore, if an assistant employed in an "open shop," and not qualified either under the Medical or the Pharmacy Acts, "sells," in the sense above defined, a scheduled "poison," he may be summoned and fined, though the doctor who employs him is not deemed guilty of any legal offence. To meet this position the General Medical Council issued a "Notice" to the effect that a doctor concerned in a transaction such as is here described, though he may escape the law, is liable to be found guilty of infamous conduct in a professional respect.

It is out of a rule framed to meet these narrow and exceptional circumstances that Messrs. Sanderson and Rayner have been able, through wearisome and irrelevant comments on medical etiquette and professional traditions and practising chemists and the spirit of the law, to arrive at this large and quite incorrect conclusion—namely, that doctors must not employ "unqualified dispensers." The statement itself displayed want of knowledge, but the reasons now given in its support combine with other considerations to compel the conclusion that its sponsors are not yet qualified to guide either the medical or the legal profession in the law and tradition of medical practice.

MIGRAINE AND ACETONURIA.

SIR,—May I be allowed to say that my personal experience corresponds with that of Dr. Allison (January 22nd, p. 165)? I have avoided sugars, jams, etc., for the greater part of my life. About sixteen years ago I took a spoonful of marmalade with my breakfast; in less than half an hour an intense headache came on, and continued till I went to bed towards midnight. Sugar in tea or coffee has the same effect, quickly followed by acidity and burning at the pit of the stomach. I am, in addition, very thin and muscular.—I am, etc.,

London, S.W.6, Jan. 21st. J. FLETCHER.

SIR,—May a belated note from a far country, following the paper and discussion on migraine at the Annual Meeting at Nottingham (BRITISH MEDICAL JOURNAL, October 30th, 1926, p. 765), be excused on account of its offering a suggestion for relief in that condition?

I too was a sufferer, one of the fifth generation of sufferers, propagated through the female line, complicated by acute gout, and always precipitated by exposure to cold or irregularity of meals, preceded by a feeling of cerebral discomfort, closely followed by general headache, a boring throb at the back of one eye, subsequent sickness, and gradual recovery, accompanied by free secretion of watery urine. Thirty-eight years ago, when about the age of 40, I read a paper by my beloved teacher and the kindliest of Scots, Sir Lauder Brunton, and from that time migraine held no terrors. The cause, in my case, was the presence in the blood of effete products of digestion, my liver having "gone on strike."

Whether this brought about one of the possible causes of migraine, of which, according to the meeting at Nottingham, we may apparently take our choice—namely, spasm and dilatation of meningeal or cerebral arteries, congenital smallness of the sella turcica, enlargement of the pituitary gland, eye-strain, retinal changes, a passing block of the foramen of Monro, or a lesion in the chiasmal region—I do not know, but I do know that Lauder Brunton could cure it, and I myself (*longo intervallo*) have never known a failure.

As to the etiology of the disease, it may be summed up in two words—"high living"—for I take it to be true that few men have seen a migrainous patient whose grandfather lived on beans and bacon, oatmeal porridge, or potatoes. And this is a point perhaps more easily demonstrated in Australia than at home.

The suggestions as regards treatment were as indefinite as those as to the cause. After the recital of many, which may be included under the title "general," we come to the particular—namely, the administration of luminal for an indefinite period; the result was uncertain; the intravenous injection of "afenil," the technique requiring the greatest care, and the result was also indefinite; and, failing these, an operation for cerebral decompression.

Lauder Brunton's prescription of 20 grains of sodium salicylate and 15 grains of potassium bromide always brought relief in half an hour, saved me many hours of pain, and perhaps even—who knows?—a cerebral decompression!—I am, etc.,

Old Beach Road, Brighton, South Australia, Christmas, 1926. J. W. YEATMAN.

ANTHRAX AT THE ZOO.

SIR,—Having been responsible, on behalf of the Ministry of Health, for investigation of the circumstances of the recent outbreak of anthrax in the elephant house at the Zoo, you will perhaps allow me to correct certain inaccuracies in the article which appeared under the above title in last week's issue of the JOURNAL.

You say that "Thanks, however, to the very prompt diagnosis of anthrax in the animals by Dr. Scott—he had diagnosed it within an hour of the necropsy—immediate and energetic steps were taken," etc. It is true that on the death of the *second* elephant Dr. Scott was able thus rapidly to arrive at a diagnosis of anthrax, subsequently confirmed by cultural and experimental methods. But as regards the *first* necropsy, such diagnosis of anthrax unfortunately was not possible, for the reason that, owing to the length of time that had unavoidably elapsed between the death of the elephant and the necropsy, microscopic examinations revealed only an enormous growth of *B. welchii*. Accordingly the cause of death was tentatively entered as "haemorrhagic septicaemia." Nevertheless, as the appearance of certain of the internal organs gave rise to a suspicion of anthrax, all precautionary measures were taken as if the presence of the disease had been definitely determined. It was not until about a week later, when a man, who had taken part in the work of the first necropsy only, was found to have developed a typical malignant pustule, that it was possible to be certain as to the cause of death in the elephant first affected.—I am, etc.,

London, N.W.3, Jan. 24th. S. MONCKTON COPEMAN.

*** The additional information Dr. Monckton Copeman provides clears up the only point that was obscure. Apparently the *post-mortem* examination of the first elephant took place too long after death to permit the identification of the anthrax bacillus; this was effected by Dr. Scott in the case of the second elephant, upon which the *post-mortem* examination was, we understand, performed before the man who had assisted in the first was known to have developed anthrax.

SMALL-POX AND VACCINATION.

SIR,—If Dr. Killick Millard's letter in your issue of January 22nd (p. 163) is to be understood as it is written, his opinion has apparently undergone considerable change since we last heard from him on this subject. As far as I could understand from his former contributions, Dr. Millard's *bête noire* was not "vaccination." It was not even "infantile vaccination." He believed that recent and efficient vaccination protects against small-pox, and he showed by his practice, as well as by a particular experiment which he quoted, that the *individual infant* is certainly protected by vaccination. He appeared to be doubtful whether the vaccinated infantile community was or was not protected, but he was quite clear in stating that it was "compulsory infantile vaccination" to which he was opposed.

Now Dr. Millard says: "Under these circumstances vaccination proved quite incapable of preventing widespread and fatal epidemics," and in illustration of this extraordinary statement he refers to the Sheffield, Warrington, and Middlesbrough classics. Is this really Dr. Millard's opinion? Is his omission of the qualifying words "compulsory infantile" intentional or unintentional?

Under present conditions in this country in regard to small-pox and its prevention, any medical statement or opinion should admit of no misunderstanding, and should be made only under the clearest sense of responsibility. It is very essential also in dealing with this subject to bear in mind that there are others who quote extracts from medical writings on vaccination, and do so for a reason very different from the reason which has induced me to criticize Dr. Killick Millard's letter.—I am, etc.,

Dartford, Jan. 22nd. A. F. CAMERON.

THE HISTORY OF DIPHTHERIA.

SIR,—I think that both Fleet Surgeon Home and Sir Humphry Rolleston have been led astray—the one by a natural zeal for the memory of his ancestor, the other by reliance upon a speculation put forward by the late Professor Adami. The disease we now know as diphtheria was sharply cut before the time of Bretonneau, and Francis Home was not the first to describe it separately. In support of my statement I would refer to several historians, of whom Bretonneau himself would be the first (see his second memoir, 1821). I am very far from wishing, however, to belittle the value of Bretonneau's work. He put our knowledge of the disease on a firm basis, and gave us a convenient name for it. But though Bretonneau's classical writings were published during the years 1821 to 1826, his views about diphtheria do not appear to have become diffused on this side of the Channel for many years. Nearly twenty-five years after the date of Bretonneau's first memoir diphtheria was not separately described in the great textbook of medicine of those days, Sir Thomas Watson's *Lectures on the Principles and Practice of Physic* (at any rate in the second edition, 1845, which is the one I happen to possess), nor are the words "diphtheritis" or "diphtheria" mentioned in it.

Though Francis Home certainly recorded a few cases of tracheal (and probably also laryngeal) diphtheria, I am sorry to have to say that the publication of his small book of sixty pages led to much confusion. It was the means by which the word "croup" was introduced into the medical literature of this and other countries. "Croup," a vulgar word applied in Scotland to the noise made by frogs, crows, cranes, and children affected with laryngeal spasm and obstruction (whatever the cause), was employed by Home to indicate a definite disease. No one who was a medical student forty to fifty years ago can forget the confusion not only he but his teachers floundered in over the disease and the word "croup." The confusion still lingers. I have asked many a third-year student attending my class at Homerton or Hampstead what he understood by the term "croupous" as applied to pneumonia, and though nearly all of them were acquainted with that use of the adjective, there was only one who could give me a correct answer.—I am, etc.,

Hemingford Abbots, Jan. 23rd. E. W. GOODALL.

INFANTILE PARALYSIS: THE BROADSTAIRS OUTBREAK.

SIR,—I am much obliged to you for inserting my report on the Broadstairs outbreak of infantile paralysis in 1926 in your issue of January 15th (p. 113).

As regards the possibility of infection having been introduced from abroad, I do not wish to emphasize this unduly, and in view of further information I have received I think it is desirable that for the sentence, "At another school the first case, an abortive one, was that of a boy who spent his holidays in Brittany," the following should be substituted: "At another school a boy who had symptoms which were suggestive of the disease had visited Switzerland during the summer holidays."—I am, etc.,

Broadstairs, Jan. 25th A. M. WATTS.

INSURANCE OF MOTOR CARS.

SIR,—You are aware that pressure is being brought to bear to secure a substantial increase in motor car insurance rates in the general market. But for the next twelve months the premiums for the Doctors' Special Policy, issued through the Medical Insurance Agency and underwritten at Lloyd's, will remain unchanged.

In addition the underwriters have, as from the beginning of this year, agreed to cover without further premium medical expenses up to 25 guineas in respect of personal injuries that may be sustained by the assured, his paid driver, or any passenger in the car. Morris-Cowley cars can be covered for the full comprehensive insurance benefits at a special premium of £11, whilst the Morris-Oxford is catered for under the special 13.9 rating.

In order to make clearer the restriction relating to the "named driver" allowance, the wording has been altered as follows:

> "If driven solely by one named driver
> Name.....
> This reduction is not allowed in the case of paid servants or chauffeurs."

The position is thus no longer ambiguous, but our opinion that the choice of this restriction is unwise remains unaltered.—I am, etc.,

L. FERRIS-SCOTT,
Secretary of the Medical Insurance Agency.

British Medical Association House,
Tavistock Square, W.C.1.

CANCER AND TRAUMA.

SIR,—May I trespass upon your space to ask if anyone has met with the development of a tumour in a wound inflicted upon a combatant during the late war? If mere traumatism can induce carcinoma or sarcoma it would be natural to expect examples from so great a wealth of material.—I am, etc.,

London, W.1, Jan. 24th. G. LENTHAL CHEATLE.

Obituary.

EDWARD STEPHEN PASMORE, M.D., M.R.C.P.Lond.,

Medical Superintendent, Croydon Mental Hospital.

ON January 12th there passed away, after a brief illness, one of the most ambitious spirits in psychiatry in the personality of Dr. E. S. Pasmore, medical superintendent of the Croydon Mental Hospital.

Edward Stephen Pasmore was born in 1866, and entered as a student at University College, London, in 1885. He graduated M.B.Lond. in 1890, and became M.D. in the following year and M.R.C.P. in 1897. He first devoted himself to neurology, and served as a clinical assistant to the National Hospital for the Paralysed and Epileptic and other neurological hospitals. In 1895 he took up psychiatry and was appointed junior medical officer and pathologist at Banstead Mental Hospital, where ultimately he became second assistant medical officer, which rank he held when he, in 1903, was appointed medical superintendent of the new asylum then in the course of erection by the borough of Croydon.

Early in his career as a mental specialist he adopted advanced ideals in regard to mental institutions and the treatment of mental disorders, many of which he was able to put into practical application in the mental hospital over which he was called upon to preside in 1903. As exemplifying this it may be recorded that Mr. Akers Douglas, then Home Secretary, on April 21st, 1904, sanctioned the Croydon Borough Asylum being known for the future as the Croydon Mental Hospital; that was a new departure, and it has since been very generally adopted by other local authorities. With this change of name the hospital received an up-to-date equipment for the practice of surgery and other special branches of medical science as adjuncts to the treatment of mental illnesses, which was largely in those days limited to general medicine and moral and personal influences.

From the beginning Dr. Pasmore kept well abreast with the growth of modern psychiatry, contributing here and

there such help as his experience and study enabled him to afford. He made some suggestive contributions to psychiatrical literature, but his best work lay chiefly in practical directions as head of the institution which will for ever be associated with his name. He was a well known figure in psychiatric circles, a fluent speaker, and always both willing and anxious to help in any movement for the better care and treatment of the mentally afflicted. For the past few years he was an honorary inspector of the hospitals of the League of Mercy, and held the Order of Mercy. He was an honorary demonstrator in the psychological department of University College Hospital, and an examiner in psychological medicine for the Royal Medico-Psychological Association, which he joined in 1898.

Dr. Pasmore married, in 1907, Miss G. E. Screech of Yelverton, and leaves a widow, two sons, and a daughter to mourn him. He was buried at Warlingham Parish Church on January 15th.

Dr. F. A. STEWART HUTCHINSON of Hove died from angina pectoris on January 6th, aged 57, at Maloja in Switzerland, where he had gone with a party to engage in winter sport. Dr. Hutchinson was the youngest son of the late General C. W. Hutchinson. He was educated at Cambridge University and the London Hospital, and graduated B.A.Camb. with honours in the Natural Sciences Tripos of 1891. He took the diplomas of the English Conjoint Board in 1895; in the following year he graduated M.A., M.B., B.Ch.Camb., and proceeded M.D. in 1905. He had served as house-surgeon to the London Hospital, resident surgical officer at the Kasr-el-Aini Hospital, Cairo, and assistant surgeon to the Sussex Eye Hospital. Dr. Hutchinson was a member of the Brighton and Sussex Medico-Chirurgical Society and of the Brighton Division of the British Medical Association. A colleague writes: "Hutch," as he was known to his many friends, was the beau-ideal of what many of us would like to be as doctors. Calm, unruffled, with a friendly smile, a wonderful gentleness and sympathy, and an unfailing desire to do always what was best for those who trusted him, it was small wonder that he was idolized by his patients. He never failed them, and in him doctor and friend were indeed synonymous. In the latter days of his war service in France he became subject to disquieting heart symptoms, and though often handicapped by these in the following years, he never allowed them to interfere with his work, or himself to be influenced by them. When off duty or on holiday he was like a schoolboy, full of enthusiasm and gaiety. In the summer he would go off to Scotland to fish or golf or walk over the hills, and for a short fortnight in January he went, year after year, to Switzerland for ski-ing and skating. Hutchinson was an accomplished skater and was one of the oldest members of the famous "Bear" club, which now has its headquarters at Morgins. Though high altitudes would have seemed hardly the best thing for him, he always declared himself to be immensely benefited by these holidays, and no one privileged to share them with him could wish for a more delightful companion. It was on the first day of his stay at Maloja this year that the end came quite suddenly from heart failure. He was out ski-ing with friends, and keenly enjoying the exercise and sunshine when he fell without a word. And so passed, in a way we think he would have wished, a very lovable soul and a very perfect gentleman, to his Maker from Whom, as was truly said by a friend, he was never very far, either in thought or act.

Dr. HAROLD HEBBLETHWAITE of Burley-in-Wharfedale died on January 3rd, aged 64 years. He was the son of the late Mr. John Hebblethwaite, a Bradford merchant, and received his early education at Bradford Grammar School. He then studied medicine at the Yorkshire College, and took the diplomas of M.R.C.S.Eng. and L.S.A. in 1887. In the following year he went to Burley and succeeded to the practice of the late Dr. Murray, whose eldest daughter he married. During the whole of the forty years at Burley Dr. Hebblethwaite had been medical officer of the village. He took great interest in the public life of the district, especially in connexion with the work of the St. John Ambulance Association and of the Sick Nursing Association. Under his supervision the local brigade won outright the Wharfedale ambulance trophy, after having won it three times in succession and five times in all. He had held a commission as major in the old Volunteers, and was afterwards associated with the local contingent of Territorials. At the outbreak of the great war he volunteered for service, and acted as medical officer of the Prisoners of War Hospital at Brockton Park, Staffordshire. In 1910 he had been appointed one of the Burley representatives on the Wharfedale Poor Law Guardians and continued in that capacity up to the time of his death. Dr. Hebblethwaite was medical officer to the Post Office and a member of the Bradford Division of the British Medical Association. He leaves two sons and one daughter.

Dr. DAVID WILLIAMS WHITFIELD, who died on January 4th, after a long illness, was born in Shropshire in 1861, and received his medical education at the Ledwick School of Medicine, Dublin, and in London. He obtained the diplomas of L.R.C.P.I. and L.M. in 1882, and the M.R.C.S.Eng. in 1883. After holding the appointment of assistant medical officer to the Whitechapel Infirmary for eighteen months, he started practice in Manchester, where he remained for seven years. He then acquired the practice of the late Dr. James Procter at Iron Bridge, Shropshire, where he lived for twenty-three years, marrying Dr. Procter's daughter in 1901. During the war he served on the Army Medical Board of the Western Command at Chester, and, after the death of his wife in 1917, commenced to practise at Abbots Bromley, Staffordshire, where he held the appointment of medical officer to the school of St. Mary and St. Anne. Ill health compelled him to retire in 1924, and, after spending twelve months in Devonshire, he went to live near Coventry, where he died. He was a member of the British Medical Association, and shortly before his death wrote the clinical memorandum which is printed in our present issue at page 187.

Dr. BRIAN RIGDEN, who died on January 15th, at his residence in Newnham-on-Severn, at the age of 70, was the son of Mr. George Rigden, who practised in Canterbury from 1837 to 1901. Dr. Brian Rigden was educated at King's School, Canterbury, and University College Hospital; he obtained the diplomas M.R.C.S.Eng. and L.S.A. in 1879. After holding the appointments of obstetrical assistant to University College Hospital, and clinical clerk to the Hospital for Women, Soho Square, he joined his father at Canterbury, and later succeeded him as surgeon to the Canterbury Dispensary in 1901; he retired in January, 1923. Dr. Rigden had been for many years a member of the British Medical Association, and was an ex-president of the East Canterbury Medical Society. He took great interest in the St. John Ambulance Association and was an honorary associate of the Grand Priory of the Order. He was well known also as an antiquary and in particular as an authority on old Canterbury. He leaves one daughter and three sons, one of whom is in the medical profession.

Dr. AUGUSTUS CECIL RENTON, who died on January 7th, at the age of 38, at his residence in Chester-le-Street, was the eldest son of the late Dr. W. M. Renton, and his family have been connected with the medical profession for many generations. He was educated at Epsom College and Edinburgh, where he graduated M.B., Ch.B. in 1912. During the war he held a commission in the R.A.M.C., saw active service in Mesopotamia, and rose to the rank of temporary major. A severe attack of dysentery while on active service considerably impaired his vitality during the following years. He held the appointment of medical officer to the Chester-le-Street Poor Law Institution, and was also public vaccinator, and compensation officer for the Harraton Colliery. Dr. Renton was a member of the British Medical Association.

The Services.

R.A.M.C. PROMOTION EXAMINATIONS.

IT is officially announced that in the examinations in March and October, 1928, of majors of the R.A.M.C. for promotion, the following periods of military history have been selected: The German offensive in 1918 and the final advance in 1918: as covered by the Official History of the War, Medical Services, General History, Vol. III (chap. xii-xvii).

DEATHS IN THE SERVICES.

COLONEL DANIEL O'CONNELL RAYE, Bengal Medical Service (ret.), died at Lacks Yews, Mattingley, on December 29th, 1926, aged 84. He was born at Kilmainham, Dublin, on August 4th, 1842. His mother was a sister of the famous Daniel O'Connell; and, when he was born, was living with her brother, who was then a political prisoner in Kilmainham jail. He was educated at Queen's College, Galway, and in the school of the Royal College of Surgeons, Ireland; he graduated M.D. in the Queen's University, Ireland, in 1865, and took the L.R.C.S.I. in the same year; he became F.R.C.S.I. in 1874. After post-graduate study in Paris and Vienna, he entered the I.M.S. as assistant surgeon on March 31st, 1866, and soon after his arrival in India served in the Daphla campaign on the North-East Frontier of India. On his return from active service he was posted to civil employ in the Central Provinces, where he was for a short time civil surgeon of Nimar, but before long was transferred to Calcutta as *professor of anatomy in the Calcutta Medical College*, and second surgeon to the College hospital. In 1892, when the late Colonel Kenneth McLeod retired, Raye succeeded him as professor of surgery and first surgeon, but two years later he was promoted to surgeon-colonel, and appointed inspector-general of civil hospitals in the Punjab; he retired after five years' tenure of that post. In 1900 the honorary Fellowship of the College of Surgeons was given to him. At the time of his death there were only three retired officers of the Bengal Service senior to Raye, and the great majority of his contemporaries have passed away. But there are still a good many younger men living who served under him successively as resident medical officers in the Calcutta Medical College Hospital, who remember him well as a first-rate surgeon, careful and safe rather than brilliant, and as always a kindly and considerate friend to his juniors in the service.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

AT a congregation held on January 21st the following medical degrees were conferred:

M.D.—J. B. Hance, A. E. Roche, J. H. Hannan.
M.B., B.CHIR.—H. A. Ware.
M.B.—A. W. Spence.
B.CHIR.—*J. L. Morgan.

* Admitted by proxy.

UNIVERSITY OF WALES.

THE following candidates, having already been approved in two of the three subjects—medicine, surgery, obstetrics—have now been approved in the remaining subject as indicated, and have completed their qualification for the degrees of M.B., B.Ch.: *Medicine*, Thomas Jones; *Obstetrics*, Ann C. Evans, Florence M. Wallen.

One candidate satisfied the examiners in surgery, and one further candidate satisfied the examiners in obstetrics, but publication of the names is withheld pending completion of their qualifying scheme for the degrees of M.B., B.Ch.

UNIVERSITY OF DUBLIN.

AT the Later Winter Commencements held in Hilary term, on January 18th, the degree of Doctor of Medicine was conferred on M. D. Fox and Elsie A. Burns.

CONJOINT BOARD IN SCOTLAND.

THE following candidates have been approved at the examination indicated:

FINAL EXAMINATION.—*Medicine*: V. Nath, J. Williams, J. Hall, O. S. Crowthers, J. E. D. Mendis, [illegible] Ralston, J. J. Craig, R. Abrahams, J. S. [illegible] very: A. B. Paul, O. S. Crowthers, [illegible] Cooper, T. G. McIntyre, J. J. Craig, an[illegible] Paul, V. Nath, [illegible] O. S. Crowthe[illegible] T. G. McIntyre, A Lipschitz, J. S. Fernand[illegible] R. Ball. *Medical Jurisprudence*: A. J. Pin[illegible] T. Sodah, N. W. Laing, R. A. F. M. Saunder[illegible], Violet D. Hunter, R. G. McInnes, J. W. Galloway, I. MacG. Chisholm, and N. S. Fraser.

Of ninety-three candidates entered the following, having passed the final examination, were admitted L.R.C.P.E., L.R.C.S.E., L.R.F.P. & S.G.:

E. A. Y. MacKeown, A. S. Arora, H. W. Bambridge, H. T. J. Abeyesundere, S. R. Carthegasam, Emma Hughes, A. A. Razzak, J. H. Sturges, R. J. Ormsby, A. M. Kulatillake, S. Caller, R. G. Paul, E. G. Marcus, E. P. Kelly, Lucy W. MacDougall, D. F. *Jayamaha*, I. G. Sutherland, H. Taylor, B. A. Van der Gert, R. R. MacGibbon, A. Kouchouk, H. G. Hebard, R. A. Paton, C. F. Schilling, A. W. Dunn D. Ross, O. ap V. Jones, L. M. de Silva, S. P. B. Gunawardena, P. J. Bourke, and S. A. Gunawardana.

Medical News.

The Forens Institute of Otology at the Middlesex Hospital will be opened on Tuesday, February 8th, by H.R.H. Prince Arthur of Connaught, chairman of the Governing Body of the hospital.

THE annual dinner of the Hunterian Society will be held at the Hotel Victoria, Northumberland Avenue, London, on Thursday, February 10th, at 7.30. Among the guests will be the Lord Chief Justice and the Lord Mayor and Lady Mayoress of London. The price of the dinner (exclusive of wine) is 12s. 6d. Full particulars can be obtained from W. E. Tanner, Esq., M.S., 38, Queen Anne Street, W.1.

THE anniversary of Sir Francis Galton's birthday will be celebrated by the Eugenics Society on Wednesday, February 16th, when a dinner will be held at the Hotel Rembrandt, at 7.30 p.m. Dr. A. F. Tredgold will give the Galton Lecture; his subject is mental disorder in relation to eugenics.

AT the annual general meeting of the Medical Officers of Schools Association on Friday next, February 4th, Dr. James Collier will deliver an address entitled "Some personal impressions upon the symptomatology and diagnosis of *poliomyelitis*." *The meeting will be held at* 11, Chandos Street, Cavendish Square, at 5 p.m.; tea at 4.30.

A CONFERENCE on maternity and child welfare, under the auspices of the Society of Medical Officers of Health, will be held at Newcastle-upon-Tyne, from February 10th to the 12th. Dame Janet Campbell will preside over the conference, and papers will be read on infant feeding, the development of maternity and child welfare work, and the prevention of stillbirth. On Saturday (February 12th) visits will be paid to various child welfare centres, sanatoriums, and convalescent institutions. Medical practitioners who desire to attend part, or the whole, of the conference, may obtain further information from Dr. A. F. G. Spinks, 20, Victoria Square, Newcastle-upon-Tyne.

THE Post-Graduate Hostel (Imperial Hotel, Russell Square, W.C.) has called a general meeting of vice-presidents and those interested in post-graduate work for Monday, January 31st, at 6.30 p.m. At 9 o'clock the same evening Sir Thomas Horder, Bt., will preside at an address to be given by Sir Arthur Robinson, Secretary to the Ministry of Health, on "*Our duty* to colonial visitors," to which ladies and friends of medical men are invited. On February 2nd, at 9 p.m., Sir William Willcox will discuss parenteric infections. Dinner (5s.) will be served each evening at 8, and coffee and biscuits can be obtained at 10 o'clock.

THE Fellowship of Medicine announces that on February 3rd, at 5 p.m., Mr. Carson will give a lecture on complications of gall stones. A surgical demonstration will be given by Mr. Paterson at the London Temperance Hospital on January 31st at 2 p.m., and a lecture on non-paralytic squint will be given at the Royal Westminster Ophthalmic Hospital on February 3rd, at 5 p.m., by Mr. Brewerton. At the Royal Northern Hospital on February 1st, at 3.15 p.m., Drs. McKinstry and Ellison will demonstrate laboratory methods in clinical medicine. The above lectures and demonstrations are open to practitioners without fee. On January 31st St. John's Hospital will begin a four weeks' course in dermatology. The London Lock Hospital is holding a course in venereal diseases from February 7th to March 5th. On February 7th a course in children's diseases will be held at the Paddington Green Hospital and the Victoria Hospital for Children. From February 21st to 25th the Royal Northern Hospital will hold a practitioners' course in general medicine and surgery; there is no fee for this. In March there will be special courses in diseases of the chest at the Brompton Hospital, in diseases of children at the Queen's Hospital, *in gynaecology at the* Chelsea Hospital for Women, in ophthalmology at the Royal Eye Hospital, in orthopaedics at the Royal National Orthopaedic Hospital, and a practitioners' course at the London Temperance Hospital. Practical courses in anaesthetics and obstetrics can be arranged. Copies of all syllabuses of the special courses and of the general course programme are obtainable from the Secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1.

AT the recent annual general meeting of the International Society of the History of Medicine it was decided that representatives of Germany, Austria, and Hungary should be admitted to membership of the society and take part in the congress to be held at Leyden and Amsterdam from July 18th to 23rd. Canada also is invited to join the Society and send representatives to the Congress.

ON his retirement after forty-two years' service as medical officer of the Driffield Poor Law Institution Dr. A. T. Brand has been presented by the officers, present and past, of the Driffield Union with an inscribed silver cigar-box.

THE department of zoology of the University of Edinburgh is to be rebuilt and £41,000 is already in hand for this purpose. The Education Board of the Rockefeller Foundation has now given an additional £38,000 for the buildings, and the offer was gratefully accepted by the University Court on January 24th. The Board has also given £10,000 for equipment and £26,000 for endowment. The total of the Rockefeller gift is, therefore, £74,000.

THE London Hospital has received from Mr. Bernhard Baron, the tobacco manufacturer, a gift of £25,000 for the endowment of the Pathological Institute bearing his name, towards the cost of which he has already given £10,000.

THE Universities Bureau of the British Empire (50, Russell Square, W.C.1) has published a classified list of students from the Dominions overseas and from foreign countries, who are now studying in the universities and university colleges of Great Britain and Ireland. In all 4,596 names are included: of these 1,754 come from Asia, 1,054 from Africa, 824 from America, 643 from Europe, and 321 from the Pacific. The price of the list is 1s. The Bureau has also published a catalogue of the professional schools, post-graduation courses, and specialist studies in the universities and university colleges of Great Britain and Ireland. Mention is made of special subjects for the study of which facilities are provided in certain universities and colleges.

DR. JOHN MOORE SWAIN, of Long Clawson, Leicestershire, attained his 100th birthday on Saturday, January 22nd. He took the L.S.A. in 1849 and the M.R.C.S. in the following year, and he was one of the first to register under the Medical Act of 1858. The Belvoir Hunt had arranged to celebrate Dr. Swain's birthday by meeting in front of his house, but owing to a heavy snowstorm the meet had to be abandoned.

THE fourth annual report issued by the Local Voluntary Hospitals Committee for the City of Manchester contains the accounts and statistics for 1925 of seventeen voluntary hospitals and kindred institutions of the city. The net deficit of the hospitals for the year under consideration was £10,541 less than that of the previous year. The income increased by £22,650, and the expenditure by £12,109. Statistical information is given about the work of the hospitals, their income and expenditure; their position in regard to investments; the numbers, cost, and nature of disability of out-patients and in-patients; and statements of accounts of the Hospital Sunday Fund, the Hospital Saturday Fund, and Alexandra Day Fund. It is noted with regret that the numbers on the waiting list continue to grow. Two diagrams are inserted to illustrate the relative shortage of ordinary income in comparison with ordinary expenditure, and the growth of the waiting lists in respect of surgical and medical cases.

THE annual report for 1925-26 of the Society for the Provision of Birth Control Clinics states that six new centres have been opened during the year; so that there are now three clinics in London, four in the provinces, and two in Scotland, affiliated to the pioneer clinic at the Walworth Women's Welfare Centre. It appears that instruction or advice was given in 3,299 new cases, while there were 4,454 return visits to the clinics. At Walworth instruction is given to doctors and nurses in contraceptive technique. The report contains several letters from grateful recipients of advice, and the society seems to conduct its activities at a very moderate cost. Several well known persons serve on the committees of the clinics, and Sir Humphry Rolleston is president of the affiliated centre at Cambridge.

THE Astor silver challenge shield for 1926 for the most effective local baby week campaign has been won by Northampton, which won the shield in 1925 also. A banner has been awarded to the Leicester health and baby week committee and certificates of merit to Kingston-upon-Hull, Wolverhampton, Cornwall county health and baby week committee, and Swinton and Pendlebury urban district council. A second shield for smaller areas was won by Halesowen infant welfare centre.

THE late Mr. William Gibson, formerly a merchant at Valparaiso, who died in November last leaving estate valued at £113,176, has bequeathed £2,050 to the Dundee Royal Infirmary. He directed his trustees to divide the residue of his estate, on the expiry of certain life-rents, among charitable institutions subject to a codicil to take effect after the death of his two sisters, directing the payment of a legacy of £25,000 to University College to be expended in equipping a laboratory for study and research in pathology and bacteriology, to be called the Joseph and William Gibson Memorial Laboratory. This legacy is to be the first charge upon the residue.

A DISSERTATION on the work of the International Conference of the Christian Mission in Africa, held last September in Belgium, has been prepared by Mr. E. W. Smith of the British and Foreign Bible Society. It may be obtained from the International Missionary Council, Edinburgh House, 2, Eaton Gate, S.W.1, price 3s. 6d. net. In a note on this conference in the JOURNAL of July 31st last we referred to the present position of medical missionary work in Africa generally, and it may be added now that, besides scattered notes on medical subjects, Mr. Smith devotes a chapter to the medical task of missionaries in Africa.

THE Société Anatomique of Paris celebrated the 123rd anniversary of its foundation by Dupuytren on December 4th, 1803, during the commemoration of the centenary of the death of Laennec, who was one of the earliest and most illustrious members of the society.

THE Ella Sachs Plotz Foundation for the Advancement of Scientific Investigation, during the three years of its existence, has made thirty-five grants to investigators in Europe, as well as in the United States. Researches which are favoured are those directed towards the solution of problems in medicine and surgery. Applications should be sent before May 15th next to the secretary of the executive committee, Dr. F. W. Peabody, Boston City Hospital, Boston, Massachusetts.

A CERTIFICATE of health before marriage has recently been made compulsory in Turkey. In the case of men the examination will be complete, while in women it will be confined to the hands, face, neck, lips, throat, chest, and back.

PROFESSOR WILHELM TRENDELENBURG, professor of physiology at Halle, has been made rector of the university.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the BRITISH MEDICAL JOURNAL must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the JOURNAL, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the BRITISH MEDICAL JOURNAL are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediocra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

QUERIES AND ANSWERS.

CHEWING GUM AND DENTAL CARIES.

"FASTIDIOUS" recalls that much was said twenty years or so ago about decadence in the teeth of the American people. Has it, he asks, been stayed by the habit of chewing gum, which he believes to be practically universal in the United States?

INCOME TAX.

"J. R. H." is engaged as an indoor assistant, and, to do his work efficiently, has found it necessary to buy a motor-cycle combination at a cost of £75, to supplement the drugs supplied by his principal (cost £5), and to expend £20 or so on instruments. What is his approximate liability?

*** Apart from the question of expenses, and assuming "J. R. H." to be entitled only to the minimum personal allowance, his liability would be £330, less one-sixth earned income relief (=£50)—that is, £250; deduct £135 leaving £115, which, at 2s. in the £, creates a liability of £11 10s. income tax. The expense question is governed by the rules of Schedule E, which provide an allowance for expenses (other than capital outlay) incurred wholly, exclusively, and necessarily in the performance of the duties of the employment. Broadly the test usually applied is whether the incurring of the expenses is a condition, expressed or implied, of the terms of employment. We suggest that "J. R. H." should state the circumstances fully to the inspector of taxes and claim the amount expended in running costs and drugs—the motor cycle and instruments represent capital outlay.

LETTERS, NOTES, ETC.

MINERS' SHORTER HOURS.

DR. F. G. BUSHNELL (Plymouth), in the course of a further letter on this subject, writes: The three examples Dr. Allison quotes (JOURNAL, December 25th, 1926, p. 1243) to support his opinion that the strain of seven hours' work is greater and worse for the miner) than eight or nine hours' work are insufficient in numbers to establish a case, and he does not state when these ex-miners became engaged in other vocations. I reassert that reliable statistics as to miners' industrial fatigue are wanting, but extension of hours, as far as the miners are concerned, means an increase in the number of accidents, and its advisability is not confirmed on other grounds by the Samuel Commission. The marked reduction in all accidents in 1919, as compared with previous years, bears out the general conclusions in all trades that excessive working hours result in more accidents, owing to their cumulative strains. It is too marked a reduction to be accounted for by Dr. Allison's assumptions. With regard to his statement that the miners are probably the best paid class of workers in the country and that the increase in accidents in 1923 and 1924 is not due to a "worsening of the miner's wages," figures prepared for the Samuel Commission show that from 1922 onwards the miner's average earnings in real wages have been below the 1914 level, at times by as much as 20 per cent. Owing to short time it will have been even worse for large numbers. This must have had serious effects.

HERPES AND VARICELLA.

DR. ALEX. KING (Yeovil) writes: On January 6th I was called to an isolated farm house, where the family consists of husband, wife, and one daughter of about 12. The wife had a severe attack of herpes zoster. On January 21st I saw the girl with typical varicella. There is not, to my knowledge, any other case in the district; if there were I should almost certainly know.

DR. S. A. MCCLINTOCK (Christchurch, Hants) writes that he has been suffering from a typical severe attack of herpes zoster, affecting the left side of the forehead, scalp, and temple, and the eye, which is recovering from severe conjunctivitis and still has some keratitis. He first felt ill on December 26th, 1926, and the herpes zoster appeared two days later. On January 10th his three children developed typical varicella rashes. Dr. McClintock adds that he now believes that some relation must exist between herpes zoster and varicella, though, in spite of having spent most of his professional life in many places abroad, he has never previously encountered a connexion between the two diseases. No recent case of herpes zoster or varicella in the locality has come to his notice.

DR. W. BOXER MAYNE (Storrington, Sussex) has had two patients under his care who illustrate the connexion between herpes and varicella. In one case a child developed a severe attack of chicken-pox, following an attack of shingles in the mother; and, in the other, a marked eruption of chicken-pox occurred in a wife three weeks after the appearance of extensive facial herpes in her husband. In this second case the patient lived in a particularly isolated part of the country and could not have been exposed to other infections.

RHEUMATOID ARTHRITIS.

DR. W. J. MIDELTON thinks that the case described by "M.B." (January 15th, p. 124) would benefit from continuous counter-irritation. He offers to supply details of the treatment if application is made to him at 112, Charminster Road, Bournemouth.

BROMINE AND THYROXINE.

DR. JOHN W. DUNCAN (Handsworth, Birmingham) writes: Your notes on thyroxine and on the treatment of exophthalmic goitre in recent issues of the BRITISH MEDICAL JOURNAL lead one to wonder about possible bromine compounds. Bromides have been tried in exophthalmic goitre; why not replace the iodine of thyroxine and similar compounds by bromine? Is it not possible that many bromine and bromo-iodo compounds may be made to be used therapeutically?

THE TOOTH-BRUSH.

DR. ERNEST E. MADDOX, F.R.C.S.Ed., consulting ophthalmic surgeon to the Royal Victoria and West Hants Hospital, Bournemouth, writes: After clearing the mouth of pyorrhoeic teeth we have to consider the remainder, which are generally either on the borderland of infection, or at least in dangerous associations. In spite of an unimpeachable radiogram, they are almost sure to go sooner or later, unless energetic steps are taken to prevent it, for the ultimate cause, whether gastro-intestinal or otherwise, is probably still at work. So much more valuable are natural teeth than artificial that we may do our patients good service by advising their active preservation rather than leaving them to their fate. The great thing is to increase the vitality of the gums, for they are the porters to open and close the entrance of mouth organisms to the neck ligament and periodontal membrane. For this purpose I should like to commend the use of a rubber tooth-brush which, instead of bristles, presents a little forest of thin rubber fingers. Though probably designed merely as a substitute for the usual brush, I believe its best role is that of a supplement, since it is admirably adapted for vigorous massage of the gums of a kind to bring fresh blood to their deeper parts. The bristle brush should, in my opinion, be reserved for the crowns, followed by the rubber brush for the gums, for it cannot prick, infect, or irritate the surface like the bristles, and it works the gums about in much the same way as the coarse, hard food of our ancestors. The bristle brush should not be used so often—perhaps once or, at the most, twice a day—and not longer than is necessary to do its cleansing work; but the rubber one should be used, if possible, after every meal, preferably after dipping it in some warm liquid. When first purchased it is rather hard, and should be soaked for some time in hot water. It is needless to add that the dentist should be visited sufficiently often to prevent re-accumulation of tartar and that any "pockets" should be treated *secundum artem*.

SUBACUTE APPENDICITIS.

SIR JOHN O'CONOR (Buenos Aires) desires to add the following to his communication on this latent form of appendicitis published in the BRITISH MEDICAL JOURNAL, September 11th, 1926 (p. 506): In numerous instances deep digital pressure over McBurney's point failed to elicit any pain or tenderness, but—with some f exceptions—an isolated well defined painful spot has been fou on palpating over Munro's point—namely, at the outer border the right rectus muscle in the umbilical anterior superior spi line. The way to search for the spot is (after having failed find a tender spot by examination on the right side of patie to sit on his left side, and when the muscles are off guard c the flexed left finger tips deeply backwards, hugging the palpa outer edge of the right rectus sheath. If there is a "lat appendix" it is 10 to 1 the "bell will ring."

CROPPED HAIR.

DR. F. P. JOSCELYNE (British North Borneo) writes to praise *fashion among women for shingled hair, and continues:* Th may, however, be another aspect to this great sanitary mo ment among women. In some of the villages of Java a Borneo the custom prevails amongst men of allowing the hair grow long; they have practically no moustache and often pubic hair. In other villages the hair is cut short, and h moustaches are quite common. He makes the dreadful sugg tion that the European ladies who are now following the p vailing fashion may be laying the foundations of a fut generation of moustached and bearded females.

THE BRITISH RED CROSS SOCIETY.

COLONEL SIR JAMES MAGILL, honorary organizing secretary the British Red Cross Society, has written a sketch on *The Cross: the Idea and its Development*.[1] He traces the origin of idea to agreements for the care of the wounded made, from sixteenth century onwards, by contending generals. But proposal to accord international recognition of the neutral of the wounded and sick, and of the inviolability of medi personnel and ambulances, was made only a year or two af the battle of Solferino in 1859, and was urged by three writer Dunant in Switzerland, Palasciano in Italy, and Arrault France. An international conference at Geneva in 1863 laid foundations of Red Cross societies, and in 1864 the Gene Convention was formulated. In England the Red Cross Socie which came into being in 1870, was called at first the Natio Society for Aid to the Sick and Wounded in War, a cumbr title shortened later to National Aid Society. In 1898 a conf ence of representatives of the National Aid Society, the St. Jo Ambulance Association, and the Army Nursing Service Rese was held "with the object of considering the advantages wh would accrue in time of war by bringing the voluntary societies into touch with the Army Medical Service time of peace." From this conference the Central Brit Red Cross Committee sprang, and was officially recogniz in the following year. The spheres of activity of the c stituent bodies were defined by regulations. In 1905 Red Cross Council and the National Aid Society joined hands form the British Red Cross Society. A fresh Geneva Conventi was drawn up in 1906, and at the same time the form of Red Cross was definitely ordered to be the Swiss federal colo reversed. In 1908 the British Red Cross Society obtained charter. In the following year a scheme for organization voluntary aid in England and Wales, in connexion with Territorial and Reserve Forces Act, was drawn up, and nea led to disaster, for the St. John Ambulance Association withdre In 1910 a fresh scheme was issued, laying down rules Voluntary Aid Detachments and County Associations. A la part of Sir James Magill's book is devoted to an account of work of the British Red Cross Society during the great war, a a concluding chapter deals with the future of Red Cross wo in peace time and the formation of the League of Red Cr Societies in Paris in 1919. The objects of the Red Cross mo ment now include "the improvement of health, the preventi of disease, and the mitigation of suffering throughout the worl The programme is ambitious, but as the society has now reach years of discretion, its officials are unlikely to hurt the suscep bilities of other bodies with similar objects. Sir James Ma writes as an enthusiast on the successful career of the socie Consequently his readers may find the book lacking in the sp which an historical account of some of the society's difficult might give to it.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical college and of vacant resident and other appointments at hospitals, will be found at pages 35, 36, 37, 40, and 41 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 38 and 39.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 35.

THE EPILEPSIES AND LIFE ASSURANCE.*

BY

S. A. KINNIER WILSON, M.D., F.R.C.P.,

PHYSICIAN TO OUT-PATIENTS, NATIONAL HOSPITAL, QUEEN SQUARE; NEUROLOGIST, KING'S COLLEGE HOSPITAL; CONSULTING NEUROLOGIST, METROPOLITAN ASYLUMS BOARD.

OVER twenty years ago Professor Pierre Marie[1] of Paris, my old chief and teacher, wrote a paper with the arresting title, "At what age do tabetics die?" Those who know the work of this master of neurology will agree that on occasion it has been characterized by a somewhat iconoclastic rending of preconceptions or of established and conventional views from their pedestal; and the above-mentioned communication proved no exception. Marie was at pains to show that tabetics live as long as anyone else, in a general sense—that is to say, there is no clinical evidence that the disease hastens the end. This paper was written in the pre-Wassermann and pre-salvarsan era, so that if his conclusions were warranted by the facts twenty years ago it will, I think, be agreed that they should be even more justified to-day.

From the appearance of Professor Marie's communication I date my own scepticism as to not a few of the views that still are current in respect of the subjects of chronic nervous disease and their expectation of life, and under this category come some of those with whom we are at present concerned. Speaking as a neurologist, I ask myself how often have I seen an actual death from epilepsy; as far as my memory serves me, I have not personally observed any. With the help of the present registrar at the National Hospital, Queen Square (Dr. Arnold Carmichael), I have ascertained that for the years 1902 to 1925 inclusive 1,398 male and female patients were admitted there for treatment with a diagnosis of "idiopathic" epilepsy. Those who died in hospital number fifteen—that is, the death rate was 1.07 per cent. In spite of the fact that only those cases are recommended for admission which exhibit relatively serious symptoms (milder cases being treated always as out-patients) this percentage is insignificant, and far less than the hospital death rate from some other neurological diseases, such, for example, as cerebral tumour. I have not been able to define the immediate cause of death in all the fifteen fatal cases, since this would have entailed a prolonged search; but I can say that the majority died in status epilepticus, and that there were only one or two accidental deaths (for example, from asphyxia)—that is, less than half of 1 per cent. of the epileptic admissions.

Thus the impression is already left in the mind that when epilepsy as a whole is considered it cannot be regarded among the more common neurological causes of death. But this is only one aspect of the question. It may be taken that the neurologist is less likely than other practitioners to accept a diagnosis of "epilepsy," since he is fully aware of the variety of organic conditions which give rise to fits, and has probably had many opportunities of deciding whether a given "fit" should come into the "epileptic" category or not. Before any rational ideas can be obtained of the bearing of the problem of the epileptic on the question of life assurance it is imperative we should clear the ground by preliminary discussion of what is understood by epilepsy—a term that has been in vogue for generations, and enjoys the sanction of long usage.

The Nature of Epilepsy.

The first and the most important of the considerations is that "epilepsy" is a name for a symptom only; and while various "diseases" are still sometimes denominated by reference to a symptom (hemiplegia, spastic paraplegia, locomotor ataxia), the description is completely useless from the point of view of pathology. There are a dozen pathological conditions of which hemiplegia is the expression; similarly, a number of different morbid processes lead to disorder of function exteriorizing itself in the guise of a "fit." We might as well speak of "a case of cough" as "a case of epilepsy." Doubtless the reply will be that there is, as a fact, a nervous malady characterized by recurrent fits, and since we do not know its pathology and cannot give it a pathologically descriptive title it might as fairly be called "epilepsy" as anything else. While this retaliatory comment is justifiable enough, it is precisely here that the danger lies, for routine habits of thought have fixed in many minds the idea that if on rough and perhaps hurried examination organic disease is excluded, the occurrence of an occasional fit is in itself sufficient to substantiate the diagnosis of "epilepsy"—a nervous disease of unknown causation and uncertain prognosis. It is against this mode and habit of transferring to a given case of "fits" our conceptions of the elusive affection called "epilepsy" that I strenuously protest. Over and over again we see cases in which the diagnosis of "epilepsy" has been made on the occurrence of occasional manifestations belonging to the category of "fits," yet the subsequent history of the case belies the diagnosis.

Difficulties at once arise if we essay a definition of "epilepsy," not merely in regard to cases which are shown to have an organic basis, but also in respect of the so-called "idiopathic" variety itself (which, of course, is in reality epilepsy of unknown origin). Taking the latter first, we ask, On what feature or features is the diagnosis established? The answer will doubtless be, The development of fits. We next ask, What constitutes a fit? This question has received many different and sometimes mutually contradictory answers, and no definition of a satisfactory character has yet been evolved. The term has been employed for clinical phenomena ranging from a gross convulsion of a generalized kind, with cyanosis, tongue-biting, and relaxation of sphincters, to twitching of a limb or segment of a limb, even to twitching of a finger or fingers, or of part of the face, without the slightest loss of consciousness. There need not even be manifestations of a hyperkinetic character, since some conditions in which motionlessness is a feature occur in circumstances justifying their description as fits. Further, as is well recognized, recurrent phenomena of another order altogether, so-called psychical equivalents, have been included by many writers in the same category. I have several times seen uncontrollable attacks of "bad temper" both in epileptic subjects and in members of epileptic families not themselves subject to convulsions. Do we not speak of a "fit" of temper? Once more, every practitioner is conversant with the variety known as petit mal, and has also doubtless seen states characterized merely by a momentary "blank" in consciousness, without visible exteriorization of any kinetic kind—so-called *absences épileptiques*; and assuredly he has met with instances of loss of consciousness in which he has been unable to decide whether they were cases of "faint" or "fit."

In view of this disparity and diversity it is hopeless to look for a sufficiently comprehensive and at the same time precise definition of what the term "fit" is in practice used to connote. It is clearly not synonymous with convulsion, and as clearly does not of necessity imply a serious nervous condition. Thus, when we are told that a given individual is subject to fits, or has an occasional fit, we are far indeed from being authorized to assume that such a one is "epileptic" in any sinister sense.

Believing as we must, however, that an "idiopathic" clinical state of recurrent fits, seizures, attacks—what you will—is a common nervous ailment, for which as yet no constant cause has been unfolded, it is highly desirable we should recognize the existence of benign as well as of malignant varieties. In my recent Harveian Lecture[2] on "The Epilepsies" I referred to the case of a lady who had an epileptic fit at the age of 14, when her period of reproductive activity commenced, and another at 44, when it closed. Cases have come under my observation in which no more than half a dozen fits have occurred in a patient's lifetime; often enough the interval between attacks can be measured by years. And other cases are known where there has been one fit only. The truth is that by no means all "idiopathic" epilepsy is of bad prognostic significance, and it would be easy for me to cite personal experiences in regard to the relative harmlessness of many

* A Paper read before the Assurance Medical Society, November, 1926.

such cases and to the satisfactory results of treatment. I am in the habit of stressing two points when called on to gauge the outlook in cases that apparently belong to the class we are for the moment considering: (1) Are there any physical or mental "stigmata" in the individual concerned? (2) Is the family history satisfactory? Speaking generally, if the patient is not weighed down by a bad heredity, and if no physical or psychical anomalies or abnormalities are conspicuous, the prognosis is good and the case will turn out to belong to the benign group. As a matter of observation I am inclined to believe that these considerably outnumber the others, and that the stress laid on neuropathic heredity has been overdone; I consider this variety of the "disease" is constitutional rather than hereditary. In this connexion the work of Douglas Thom[3] is of no little interest. He has studied the records of 1,536 epileptic patients, of whom 1 in 6 was married; 80 per cent. of the marriages resulted in children (553 offspring traced and their history obtained). In only ten cases (1.8 per cent.) did epilepsy develop. Again, Myerson[4] quotes the superintendent of the Massachusetts State Hospital for Epileptics to the following effect: "There are practically no families of epileptics in his institution, numbering 1,500 people, and a thorough search revealed four families of eleven people!" In face of these data we must revise our old conceptions of epilepsy of unknown origin; we are certainly not justified in perpetuating the view that it is commonly hereditary, and, like all hereditary conditions, incurable; or that if we cannot find the cause of the fits in a given case it is to be relegated to a mysterious "idiopathic" class and all hope of amelioration abandoned. Such ideas are utterly out of date.

Turning, in the next place, to cases in which "fits" are found to have an organic basis, there is patently no need to be concerned with any precise definition of the symptom. It is the physiological result of a pathological state, and the latter is the condition of which we have to evaluate the significance for good or ill. Fits are recognized to be, for example, a frequent concomitant of syphilitic disease of the brain and its coverings, of intracranial tumour, of cerebral vascular disease whatever its etiology, of intracranial infections, inflammations, and toxic haematogenous or lymphogenous processes. If a person is over the age of 40 or 45 it is my invariable practice to be on the look-out for an organic basis should his complaint be of occasional fits. The epilepsy of elderly patients has very frequently indeed a vascular origin. One or two fits at intervals, generalized in character and for the time monosymptomatic, may be found to precede the development of cerebral tumour, of general paralysis, or of vascular disease outside the cerebrum. Vascular changes in the brain are a much more common cause of Jacksonian epilepsy than is intracranial tumour.

Clinical and Experimental Evidence.

A little acquaintance with clinical data of this kind is doubly useful; we are able to adjudicate on such cases of "epilepsy" by reference to the morbid process causing the epileptic symptom without getting entangled in any maze of doubt as to what epilepsy is or is not; and at the same time we remove such cases from the vague category of "epilepsy" to the definite nosological group to which they respectively belong. Speaking for the moment from the life assurance standpoint, it is an unequivocal gain if we can assess a given case as one of cerebral vascular disease and not as one which happens, *inter alia*, to exhibit epileptic phenomena.

A second important consideration is of a somewhat different kind. The evidence of the experimentalist can be advanced to prove that epileptic convulsions can be produced in animals which show no signs of disease in any pathological sense. A healthy animal which is being bled to death may develop convulsions *sub finem*, while the respiratory centres are failing. Tetanization of the motor cortex will, under suitable conditions, result in convulsions. By the use of convulsants of the absinthe and thujone class fits can readily be caused in animals which are perfectly normal members of their respective species. According to Cobb and Macdonald,[5] the march of events during a convulsion produced by thujone is very similar to that seen during the epileptic fit. Elsberg and Stookey[6] have prove that these experimental toxic fits can be prevented by th circulation of Ringer's fluid through the brain. The con clusion is obvious—that the phenomena of epilepsy can an do occur in appropriate circumstances in animals which ar healthy and which exhibit no defect of neural structure.

It will, I think, be admitted that in man the greate part of the manifestations of a fit, Jacksonian o generalized, is the result of consecutive discharges o normal, stable nerve cells. I have indicated in the Harveia Lecture[7] (already referred to) the line of argument sup porting this contention, and have there drawn the con clusion that "healthy neural mechanisms may becom epileptogenous, without being in the remotest degre diseased."

If we follow this line of reasoning it may be fairly take as indicating an epileptic potentiality in any mechanis of any neural level in man provided the appropriate factor come into being. In human cases of apoplexy (thrombotic embolic, haemorrhagic, traumatic) how frequently do w not observe a fit or fits in the course of the illness, ye we never dream of regarding these patients as being th subjects of epilepsy. Their fits are the expression of disorder of function which a number of factors have com bined to produce; if the factors are removed the fits cea and leave no trace behind them. When a general paralyti or a uraemic patient has a convulsive attack we never du him an epileptic, although we say his attack has bee epileptic in character; knowing to some extent the causa tion in these particular instances we feel that if it ca be controlled the attacks will stop. If we can operat successfully on a case of Jacksonian epilepsy from cerebra tumour we have good reason for holding that the fits will in consequence disappear. In other words, only one conclusio can be drawn—namely, that any constellation of moto nerve cells may on occasion become unstable; that th cause of this instability is no innate or inherent defect o the nerve cells as such, for we have good reason to believ they are normal; that it is constituted rather by som agent (toxaemia, pressure, etc.) which it is our business t detect and counteract; if we can do so, the neura mechanisms will recover their normal functions. This con sideration should in its turn lead us to avoid confirming in our patients' minds the impression that a diagnosis o "epilepsy" has somehow a sinister significance; this is at present certainly the view of "the man in the street," and it must have been to some extent derived from medical opinion.

Lest these views should be thought to be of merely theoretical interest I may refer to experiences in regard to what has been called "war epilepsy." However much one is disinclined to accept in full the arguments and inferences of Pierce Clark,[7] the late Dr. R. G. Rows,[8] and others who believe that "epilepsy" is a "functional mental illness," curable by "mental methods," there can be little doubt that during the war, and since, most of us have met with cases in which the apparent cause (predisposing? exciting?) of full-blown epileptic fits has been a stimulus belonging to the mental (as opposed to the physical) series. Treatment of some at least of these cases by non-physical means has resulted in an apparently abiding cure.

One case will suffice for citation. The patient was at Dunkirk during the later part of the war, and he and his mates were liable to shell attack from land, sea, and air. On one occasion he had retired to a bomb-proof shelter, which was struck, and he was "buried alive"; when subsequently rescued he was found to be unconscious. Some time after the war was over he was in a cinema in South London with his fiancée. The place was dark and stuffy, and by some association there came into his mind a memory of the dugout at Dunkirk. At that very moment the orchestra began to play Rachmaninoff's well known prelude, which, as he, a student of music, was aware, is supposed to represent the feelings of someone who is being buried alive. Within a minute or two he lost consciousness, and developed a full epileptic fit, with tongue-biting and incontinence. He was treated by psycho-therapeutic means, and has had no further epileptic attack.

Cases of this kind are no war novelty. They were recognized long ere the world conflict caused them to reappear in some numbers. Their significance resides in the apparent causation of physical fits by psychical excitations; if the latter can be checked the physical (neural) mechanisms pursue their normal activity undisturbed.

The practical lesson to be learned from the preceding discussion is, I submit, that the epileptic seizure is a *phenomenon of normal nerve mechanisms, which can be* roused (or, conceivably, released) into abnormal activity as a consequence of the action of factors (or combinations of factors) of different grades and classes. Such an occurrence may be unique in the patient's experience, or may be repeated, may, indeed, become chronic; whether single or multiple, the fit is itself no disease. If we will thus envisage our cases of "epilepsy" we shall be compelled to consider every case solely on its merits, and not by reference to ideas which have for too long a time led to the dismissal of any and every adjudged "epileptic" from the scope of therapeutic optimism.

I may turn now to the application of these considerations to the problem of the epilepsies as it confronts the officers of life assurance societies.

Prognosis as to Life.

In the first place, it seems fairly certain that medical decisions and office practice have been influenced and moulded, in some instances, by traditional conceptions as to the nature of epilepsy. It has been regarded, in its "idiopathic" form, as a chronic and incurable "disease," and its subjects have been held to be uninsurable. Doubtless, also, practice has been determined by the view that an element of risk is inherent in all cases, and forms an insuperable objection to acceptance. Possibly, indeed, the reader may be impatient of any effort to discriminate among the epilepsies, holding that every fit—organic, hysterical, psychogenic, idiopathic—is a risky affair, and its pathogenesis immaterial. The risk, we may be sure, is thought to be one of injury or death. Let us endeavour in some degree to assess it.

According to Sir William Gowers,[9] "the danger to life in epilepsy is not great." Some of us have often seen the most severe fits passed through with apparent impunity, and conclude that in the fit itself the danger to life is minimal and negligible. The contention is rather that risk of "accident" accompanies every fit, in greater or less degree, and I have no thought of denying its existence. Deaths from choking, suffocation, burning, drowning—all are known and admitted. Yet in my experience of epilepsy of the "idiopathic" kind I have only had two cases of accidental death—one from smothering and one from drowning. The National Hospital figures given above indicate how trifling is the risk of a fatal termination by accident. Gowers concludes that "the danger of such accidental death is unquestionably small. The proportion of cases in which it occurs is not ascertainable, but, if all cases of epilepsy are considered, it is minute." With this conclusion I am in cordial agreement; the risk is continually and grossly overrated because its rare occurrence is allowed to colour our conceptions of the seriousness of the "disease."

However, we may approach this question from a somewhat different angle. What is the mean age at death in the case of epileptics? I quote from Aldren Turner's[10] study of the subject the following figures.

TABLE I.—*Epileptics: Mean Age at Death.*

Authority.	Mean Age at Death.
1. Spratling[11]	29.4 years
2. Snell[12]	33.0 ,,
3. Massachusetts Epileptic Institution[13] ...	39.0 ,,
4. Lord[14] (London County Asylums) ...	40.0 ,,
5. Muirhead[15] (Scottish Widows' Insurance Association)	48.0 ,,

So great is the disparity between these various figures that it is clear they must represent very different types of case. To apply indiscriminately such conclusions as these figures offer is obviously not permissible. They are vitiated, moreover, from still another point of view; we have no means of ascertaining the pathology of the cases forming the material, which has been classified solely by a symptom—a most precarious proceeding, as all must admit.

That incompleteness of classification and absence of pathological control are essential stumbling-blocks in the way of reaching any even approximate conclusion as to average duration of life or mean age at death is apparent from consideration of quite another group of statistics. From the Registrar-General's Statistical Review of England and Wales (1925)[16] I find in that year the cause of death certified as "epilepsy" in the case of 1,097 males and 1,026 females. The figures for the different age periods are as follows:

TABLE II.—*Deaths attributed to Epilepsy, 1925 (Registrar-General).*

Age Period (years).	Males.	Females.	Age Period (years).	Males.	Females.
0-1	22	12	45-50	70	68
1-5	39	30	50-55	64	74
5-10	46	18	55-60	70	73
10-15	55	39	60-65	65	68
15-20	87	75	65-70	54	71
20-25	96	77	70-75	43	51
25-30	82	74	75-80	29	37
30-35	83	94	over 80	29	23
35-40	83	67		1097	1026
40-45	80	75			

What can be legitimately inferred from the above table? It should be stated that according to the international agreement on which disease classification is based the group "epilepsy" does *not* include infantile convulsions, for which other statistical figures are supplied. The neurologist at once asks, What is the "epilepsy," separate from "infantile convulsions," which is given as the cause of death of 34 infants under 12 months, or of 103 children under the age of 5? To suppose all are cases of so-called idiopathic epilepsy is impossible. Again, has "idiopathic" epilepsy been responsible for 52 deaths at the advanced age of 80 and over? As long as "epilepsy" remains undifferentiated, just so long will tables of this kind prove nothing whatever. Taking them at their face value, however, and solely for the sake of comparison of age periods, we observe that just as many persons die from "epilepsy" between the ages of 70 and 75 as between 10 and 15, and that more live to over the age of 60, eventually to die as "epileptics," than succumb below the age of 20. I scarcely think figures of this kind favour the traditional views on the subject that still obtain currency.

We may look, in the second place, at the question of the frequency, among nervous diseases, of "epilepsy" as a cause of death—again with the proviso that this particular diagnosis covers as great a multitude of diagnostic sins as does influenza.

I have compiled from figures given in the 1925 Statistical Review (England and Wales)[16] the accompanying table.

TABLE III.—*Deaths attributed to Nervous Diseases (England and Wales), 1925.*

Nervous Disease.	No. of Deaths (Male and Female).
Cerebral apoplexy	27,031
Epilepsy	2,123
Paralysis (unstated — for example, hemiplegia, etc.)	2,098
Meningitis (all kinds)	1,814
General paralysis of the insane	1,539
Diseases of ear and mastoid	1,183
Cerebral tumour	1,035

Incidentally, the valuelessness of these descriptive terms from the only correct classification standpoint—namely, the pathological—is seen at once in their mixed character; "paralysis" is a clinical diagnosis, and so is "epilepsy," whereas cerebral tumour and meningitis are pathological diagnoses. Be this as it may, of nervous causes of death "epilepsy" ranks second, being exceeded only by apoplexy. This seems serious, but only on superficial consideration. How many of the cases of "epilepsy" were syphilitic?

How many due to cerebral vascular disease? How many the result of intracranial pressure, of meningeal or cortical inflammation, even of trauma? In none of these respects can any information be gleaned.

My next table comes from the United States Mortality Statistics (1925),[17] and embodies the figures for the two years 1921 and 1922, given, not in actual numbers, but in death rate per 100,000 of the population of thirty-seven States then in the registration area.

TABLE IV.—*Death Rates: Nervous Diseases (U.S.A.), 1921 and 1922.*

Nervous Disease.	Death Rate per 100,000.	
	1921.	1922.
Cerebral apoplexy	82.7	85.1
Paralysis	6.2	6.5
General paralysis of the insane	6.3	6.6
Meningitis	4.2	3.6
Epilepsy	3.1	3.3
Diseases of the ear	3.2	3.1

According to these statistics, "epilepsy" is not second, but fifth, on the list of killing nervous diseases, and stands practically on a par with diseases of the ear. Since here also no attempt is made to differentiate varieties of the symptom or to distinguish pathological bases for its appearance, the table in reality is valueless; if discrimination were exercised I am convinced that "epilepsy" would rank still lower in the list. As it is, there is, in my opinion, clear justification for a revision of their mental attitude on the part of any life assurance officers who may look askance at cases thought to be "epileptic," and feel inclined to drop them.

In regard to the actual practice of offices I have little information to offer. Aldren Turner,[10] who is one of the very few who have touched this aspect of an important question, cites in his book (1907) the experience of the Scottish Equitable Life Assurance Society. At that time the society had accepted twenty-three proposals, with a personal history of "fits," during a period of fourteen years. He says:

> "It ought, however, to be stated that none of them was a confirmed epileptic, but only persons who had had at some previous period of life one or more epileptic seizures. The records were examined seven years later, when it was found that two persons had died—one from tumour of the brain, the other from uraemia. Of the remaining 21 cases, the eldest was 65 and the youngest 35 years of age. . . . The average age of the 21 surviving cases was 47 years. . . . It is therefore obvious that the acceptance of these cases was a justifiable procedure, more especially as the added years ranged from five to twenty."

The first comment I may make on this interesting experience is, that the two applicants who died were not cases of "epilepsy" at all; one was a case of cerebral tumour, and the other of renal disease. Scanty though these figures are, it is a remarkable circumstance that the only two fatal cases of "epilepsy" were as a fact wrongly diagnosed. A second comment is that acceptance of these "epileptic" cases was justified by the event. Turner adds a further point of some note in this connexion. Persons rarely present themselves for insurance under 21 years of age, and more than 75 per cent. of so-called idiopathic epileptic cases have already developed symptoms by this age. The prospect is distinctly in favour of freedom from the affection as the years go on. Otherwise expressed, if there is a family history of epilepsy and if the individual proposing has not himself developed epileptic symptoms by the age of 21, the chances are greatly against his exhibiting them at a later period. Gowers estimated these chances at 50 to 1 against, and if the reader will refer to the figures quoted earlier from Myerson he will agree that this ratio overstates rather than understates the risk.

I do not hope to be able to do more than disturb a little the preconceptions of any who, accepting precedents and traditional practice, refuse proposals coming from "epileptics" of any kind or degree. Ideas dating from a less knowledgeable era have had so long a start that one doubts if they will be overtaken. Hughlings Jackson once said that it takes twenty-five years for new conceptions of disease to penetrate the mind of the profession, and if this is needlessly cynical, it at least embodies an element of truth.

CONCLUSION.

Summarizing the trend of argument as it makes its appeal to me, I may conclude as follows:

1. Epilepsy is not a disease but a symptom.

2. It is a symptom of abnormal function of normal neural mechanisms.

3. It is caused by a number of differing pathological processes.

4. These processes are the diseased processes which have to be diagnosed; *they* are the "disease," not the "epilepsy."

5. From the standpoint of life assurance it is the disease and not the epilepsy which is to be adjudicated on in the usual way.

6. Among the epilepsies is a group commonly called "idiopathic"—that is, as a fact, epilepsy of unknown origin.

7. This particular variety exists in different forms and degrees, of which perhaps the major part is benign, not malignant.

8. As an aid in differentiation, attention is to be given to the mental and physical "make-up" of the individual and to the family history and heredity.

9. Although heredity is not a negligible factor its influence has been much overestimated.

10. The risk of injury or of death in the fit itself is altogether minute.

11. The risk of injury or of death as an accident arising out of the fit has also been persistently overestimated, and is quite insignificant when epilepsy as a whole is considered.

12. Existing tables purporting to give mortality statistics in respect of epilepsy are meaningless and valueless, since the epilepsy they refer to is undifferentiated.

13. Such as they are, they do not substantiate the view that the life of epileptics is short.

14. If epilepsy of the so-called idiopathic variety does not reveal itself before the age of 21 the chances are greatly against its subsequent appearance in proportion as the years pass.

15. In my opinion a case has been made out for the individual consideration, strictly on its merits, of every case in which fits have occurred that may present itself to the life assurance medical officer.

THROMBO-ANGIITIS OBLITERANS.

BY

SIR W. I. DE C. WHEELER, F.R.C.S.I.,

SURGEON, MERCER'S HOSPITAL, DUBLIN.

THE name thrombo-angiitis obliterans was suggested in 1908 by Buerger for this interesting and remarkable disease, and has been accepted almost universally in the United States. Two cases have come under my care which illustrate the tragic and mysterious nature of its clinical manifestations.

The literature on the subject is sparse, but those who have made it a special study believe that it almost exclusively occurs in male adult Jews, especially in the poorer class of Jew who has migrated from Russia to America or elsewhere. It has been found also in Central and South-Eastern Europe, and appears to have been especially prevalent during the war. The disease is almost unknown among the inhabitants of these countries, but it has been studied by Parkes Weber in London, who admirably describes the condition in the *Quarterly Journal of Medicine* (vol. 9, 1915-16). Most of the original work comes from Leo Buerger of New York. It is sometimes referred to as Buerger's disease.

For no ascertainable reason some inflammatory condition arises in the deep vessels of the extremities, usually the legs, ending in thrombosis and obliteration, as the name implies. At the onset there may be no clinical evidence of the existence of such a condition, but as time goes on—weeks, months, or years—the organization of the inflammatory products proceeds, until finally local syncope and death may supervene. When a point is reached at which the circulation is at a minimum, and a struggle is taking place to maintain the vitality of the part, the pain often becomes unendurable, and sooner or later, in the majority of cases, amputation becomes inevitable, either for the relief of pain or in anticipation of a spreading gangrene. It is to be emphasized that the disease is pre-senile, that it is non-syphilitic, and is not embolic in origin. Frequently the disease in the arteries is accompanied or followed by thrombosis of the veins. The disease does not progress continuously; surprising changes, both for better and for worse, are the impressive features of the variegated clinical picture of thrombo-angiitis obliterans. The attempts of Nature to provide a new circulation, either by collateral anastomosis or by the canalization of the thrombosed blood vessels and connective tissues, is mentioned by all the writers. From a study of the published cases it would appear that this attempt is usually followed in the end by clinical, as distinct from pathological, failure. Thus the disease has a tendency to periodic relapse, and may end fatally when some important vessel is attacked. The two cases in Dublin which came under our care were diagnosed more by a process of exclusion than by anything tangible or concrete which could be obtained from the history or by clinical examination. Syphilis was first excluded; Raynaud's disease and the other angio-neuroses, together with endarteritis obliterans, were then eliminated. The urine in both cases was sugar-free, and there was no cardiac or other discoverable lesion remote from the affected parts. Buerger admits that only in very few cases can the symptoms justify a diagnosis in the incipient stage; it is only when we compare the history with the subsequent events that we can relegate definite signs to the onset of the vascular changes. After all, it is from the healing of the vascular lesion, with the consequent disastrous occlusive thrombosis, that the diagnosis is made. In both the cases here reported, and in nearly all the others recorded, pain in the calf of the leg, of the type known as intermittent claudication, was an early sign. An angry red colour of the foot, when allowed to hang, together with puffy toes, is a constant sign when the disease is well established.

Trophic lesions may be the first sign, and there are acute cases in which gangrene very rapidly develops. The initial symptoms may be too slight to attract attention. Both legs may be intensively involved with thrombo-angiitis obliterans, yet one shows outward signs of disease, the other, to all intents and purposes, appearing normal to the patient, but the pulse is absent in the dorsalis pedis, posterior tibial, and popliteal arteries. Cases suffering only from intermittent claudication have many times been treated for rheumatism, for gout, for flat-foot, and other orthopaedic conditions. Thrombo-angiitis obliterans in such cases is neither thought of nor looked for, but if a careful examination is made, in addition to pulseless vessels, blanching and reactionary redness becomes apparent on changing the position of the foot. A history of thrombo-phlebitis should always be sought. In one case mentioned by Buerger, of a Russian Hebrew, aged 32, all the vessels of both lower extremities, from the femorals down, were pulseless. The redness and the blanching were obvious, but there were no trophic disturbances, the patient complained of no pain, and considered himself perfectly well.

In attempting to classify the disease, Buerger suggests: (1) the typical form in the lower extremities; (2) the same with associated thrombo-phlebitis; (3) the same with involvement of the upper extremities; (4) a form difficult to diagnose in more senile patients who suffer from secondary or complicating arterio-sclerosis. I think that any one of these types may be acute, or subacute and intermittent, or chronic and intermittent.

Weber, in his close study of the disease amongst adult Jewish males resident in London, makes some interesting observations. One of his patients was aged only 1 year, and another only 2½ years, when they migrated to England from the East. He states that the affection occurs almost exclusively among Jews, but that it is not absolutely limited to the poorer classes. In nearly every case there was a history of habitual cigarette smoking (the brand of cigarette had no significance), and he thinks this is a contributory factor in producing the disease. The essential cause of the disease still remains unknown. Weber emphasizes the fact that acquired or inherited syphilis is almost invariably absent. It will be seen later that the two cases which form the basis of this communication might well have served as illustrations for his remarks.

"The characteristic symptoms of the disease are: (1) redness or cyanosis of the foot when it is allowed to rest in the dependent position; (2) pallor of the foot on movement of the ankle-joint; (3) intermittent claudication when the patient walks for a few minutes; (4) absence of pulsation in the arteries of the foot, most noticeable in the dorsalis pedis artery."

Some confusion has arisen owing to the use of the term "erythromelalgia." It was originally employed by Weir Mitchell for vague conditions of an extremity associated with pain and redness or cyanosis. It is not a diagnostic term, and might be applied to frostbite as well as disorders of functional origin, or any of the many angio-neurotic conditions. The disease never occurs in a woman. "The Jewish women," says Weber, "in the East End of London are all abstainers from tobacco; their men folk are notoriously fond of it."

TREATMENT.

The question of treatment can only be discussed in a general way. Each case must be judged on its merits. The pains may reach an intolerable pitch and call for amputation within a few weeks in acute cases. There is a difference of opinion as to whether amputation should be performed high or low. I am convinced that where there is any doubt high amputation is best. It is the well established surgical procedure for gangrene which is spreading beyond the toes. Knowing the pathology of the disease, the rules which guide us in dealing with senile gangrene may be reasonably followed. Sir Anthony Bowlby[1] says that the best course is to wait and see to what extent the collateral circulation is capable of dealing with the part. When senile gangrene is not limited to the toes, but has spread to the dorsum of the foot, amputation should be carried out without delay. The operation should be performed immediately above the knee. Buerger states that in the majority of cases amputation of at least a portion of the leg will become necessary, and that the Stokes-Gritti operation is the ideal procedure. Low amputations have been occasionally successful, but the risk of failure is too great, as is illustrated in both the cases mentioned below.

Conservative Treatment.

Buerger recommends an ingenious method of encouraging the capillary circulation, a method somewhat analogous to the contrast baths recommended by Sir Robert Jones in orthopaedic conditions. Buerger's plan is to induce reactionary hyperaemia in the affected part by a preliminary elevation of the leg followed by its depression into a dependent position. It is effectual in the milder form of cases if the pain can be tolerated. The period of elevation should be the minimum amount of time necessary to produce a frank blanching of the foot; this takes from thirty seconds to three minutes. The leg is then allowed to hang for one or two minutes beyond the time necessary for the induction of a distinct blush. The third position is that of rest with the leg horizontal. The sittings should be repeated frequently during the day. Passive hyperaemia by Bier's suction method has been helpful. The apparatus must be large enough to enclose the front part of the foot; the application is made for five to fifteen minutes three times a week.[2] Ligation of the femoral vein below the entrance of the long saphenous vein has been tried without success.[3] It is difficult to see on what basis some authorities recommend the intravenous injection of sodium citrate. The anti-coagulating action of sodium citrate in the employment of blood transfusion is followed by a coagulating effect in the case of the recipient's blood, and it is now well known that whether sodium citrate is given intramuscularly, intravenously, or subcutaneously, the result is prompt and pronounced shortening of the coagulating time. It is for this reason that injections of sodium citrate are effective in cases of haemorrhage.

Arterio-venous anastomosis has been, for obvious reasons, unsuccessful, and Leriche's periarterial sympathectomy not only failed in both the cases under review, but in every other case on record in which it was tried. For the relief of thrombo-angiitis obliterans the operation should now be abandoned. Alcohol has been injected into the posterior tibial nerve at the ankle for the alleviation of pain with success. The anaesthesia of the sole of the foot and the paralysis of the intrinsic muscles which follows make practically no difference in walking.

The outstanding features in the history of the two following cases were: (1) Neither was a Hebrew; (2) neither had syphilis; (3) both had served abroad; (4) both were heavy cigarette smokers; (5) the first patient lost portions of all four limbs during a period of about ten years; (6) the second case was of the acute variety, and the patient lost the left leg above the knee within a few weeks of the first attack of pain in his calf.

CASE I.

This patient was not directly under my care, but I saw him many times during his three years' treatment in Blackrock Hospital. The case illustrates the tragic course which the disease may follow. Up to date he has had a general anaesthetic on more than thirty occasions. The patient served during the war in the navy, at first in the North Sea, and subsequently in the tropics. He remembers that he was off duty for a day or two at a time owing to cramps in his legs. In 1915 the right foot became particularly troublesome; the big toe, he states, became white and lost sensation. These attacks were transitory. In 1919 he was admitted to the Haulbowline Hospital at Cobh (Queenstown); the great toe of his right foot had become black; it and the neighbouring three toes were removed. He was nine months in this hospital, but the wounds never healed. He was discharged, and remained at home for one and a half years. When at home the great toe of the other foot (left) became black, and he was admitted to a Dublin hospital, where a Syme's amputation was performed in 1922. The stump became gangrenous, and, as in the case of the toes of the other foot, the granulating wounds took eight months to heal. About a year later he was admitted to Blackrock Hospital with spreading gangrene of the right foot (from which the toes had been removed in 1919), and a modified Lisfranc amputation was performed. The flaps became gangrenous, and after many local operations amputation was performed below the knee. Necrosis of the bone followed, which necessitated a further operation, and a femoral sympathectomy was attempted at the same time (May, 1924, one year after admission). In 1925 the left leg (from which the foot had been removed in 1922) showed signs of slowly developing gangrene, and an amputation was performed below the knee eight months later. Once again the flaps became discoloured and gangrenous, and a month later amputation was performed in the lower third of the thigh. Almost simultaneously with the development of the gangrene in the stump of the left leg trouble commenced in the left hand. Blushing and blanching, with excruciating pain in the tips of the fingers, commenced, as in the case of the toes. The tips of the little and ring fingers sloughed off. Three months later the tips of the fingers and thumb of the opposite hand went through a similar but modified process. Mercifully, the spreading process stopped when the tips of the phalanges were protruding through the finger pulps. It became necessary, however, to amputate the first finger of the right hand. His present condition is: Left leg amputated through lower third of thigh; right leg amputated below the knee; right hand, first finger amputated, nails and tips of the other fingers involved; left hand, nails and tips of fingers also affected—the middle finger is missing from an accident in childhood. There is a distinct rubor to be seen on both ulnar and radial sides of both palms. Both radial pulses are good, both femoral arteries are pulsating below Poupart's ligament.

Raynaud's disease cannot absolutely be excluded in the diagnosis of this case, but against it is the fact that the patient was and is a robust sailor who contracted the disease at the age of 25. All the preliminary phenomena were confined to the feet. The gangrenous process was deep and destructive in the lower limbs over a period exceeding ten years. Lewis and Leichert[4] mention a similar case. They suggest ligature of the femoral artery distal to the profunda as a means of forcing and accelerating the development of collateral circulation through more healthy channels.

CASE II.

An officer, aged 28, who had served in Egypt for a number of years, in the middle of August, 1926, was boarding a ship *en route* for home when he had a sudden severe pain in the calf of his left leg. His account of the sudden pain—as if someone had hit him from behind—reminded one of the typical history given when the plantaris tendon is ruptured. On arrival home I saw the patient in consultation with Drs. O'Reilly and Wilson. The condition of the leg was quite characteristic of thrombo-angiitis obliterans. When the foot was in the dependent position it was flushed, and had an appearance as if it had been immersed in very hot water. When the foot was raised to the horizontal position only a few seconds elapsed until it became blanched and marble white. The pain then became excruciating, and could not be borne for more than a minute. When allowed to hang once again the capillary flush rapidly reappeared, and the pain was markedly relieved. The patient slept with the leg hanging out over the side of the bed, supported on a low chair and cushion. The arteries round the foot were pulseless. Nothing could be obtained from the history to throw light on the local condition, and a thorough routine examination gave equally negative results. In making the diagnosis we were faced with the fact that this patient was not a Hebrew; that he was by no means of the poor, half-fed type of patient which usually contracts the disease; in fact, he was a strong, young, athletic officer, fond of polo and pig-sticking, and many other athletic activities. Embolism was excluded in the absence of cardiac defect and of any recent illness. It was concluded also that if the limb survived the first shock of sudden arterial occlusion from embolus, in three weeks all anxiety about collateral circulation would have disappeared. The reverse occurred; each few days marked a further diminution in vascular supply. The diagnosis of pre-senile, non-syphilitic endarteritis obliterans was made, a term which in cryptogenetic cases is interchangeable with thrombo-angiitis obliterans, but not so expressive. We had hoped that, as gangrene had not actually appeared in the first two or three weeks, the collateral circulation would become more and more established in a young, vigorous man, and that the limb would be saved; but, on the contrary, the case was of the acute form; trophic sores developed on the great toe and the neighbouring toe, lymphangitis followed, and the glands became enlarged in the groin. The patient became worn out with pain, morphine had little or no effect, and amputation was performed above the knee on September 18th.

During the course of examination the patient's arteries were *x*-rayed to discover if signs of calcification were present; when the femoral artery was exposed high up to perform the Leriche operation, some days prior to amputation, it felt normal in every respect. The stripping of the artery was not attended with any unusual difficulty, such as has been reported by other writers. It was observed, however, that primary contraction of the artery when the sympathetic sheath was in the process of removal did not occur.

During the three weeks at our disposal from the time of the first pain in the calf to the amputation above the knee conservative treatment, in addition to the Leriche operation, was vigorously employed. Hot-air baths, diathermy, immersion of the foot in heated wax, to mention just a few of the remedies tried, failed to influence the progress of the disease.

Dr. T. T. O'Farrell, who examined the limb after removal, found the popliteal artery blocked by an old thrombus one inch below the level of amputation. Old-standing endarteritis was obvious here and in the vessels supplying the foot. Thrombo-phlebitis, with occlusion and calcification of the deep veins, was also found. Canalization of the thrombi and of the connective tissues completed the pathological picture.

THROMBO-ANGIITIS OBLITERANS IN ASSOCIATION WITH SYPHILIS.

(With Special Plate.)

BY

R. P. SMITH AND D. WELLS PATTERSON.

(From the Pathological Department of the Royal Victoria Infirmary, Newcastle-on-Tyne.)

As comparatively few cases of thrombo-angiitis obliterans have been reported in this country we desire to record the following instance. As will be seen, the symptoms were characterized by pain, coldness of feet, ischaemia, intermittent claudication and erythromelalgia, evidence of trophic disturbances shown by ulceration of leg and gangrene of toe, and, at a later date, extension of the *disease to the other limb.*

The patient, who is of British nationality, is a tailor's cutter, aged 59. Previous to this illness he was always healthy, and he gave no history of syphilis. The first symptoms were noticed *nine or ten years before he came* under observation, when he suffered from paroxysmal pains in the calf of the left leg; at first they came on after standing for some hours at his work, and were relieved on resting. Superficial ulcers developed on the anterior aspect of the lower third of both legs a few years later. *For the past two years the pain had increased in severity*; it was intense after walking, and was situated in the lower third of the left leg and foot. Resting gave relief, but the pain recurred on walking a short distance, say a hundred yards. These symptoms of intermittent claudication were associated with a sense of numbness or coldness, *especially when the weather was cold and* wet, and the foot became blanched and cold to touch. This transitory anaemia rapidly passed off on resting. The family history revealed nothing noteworthy. The patient is married; his wife and two children are alive and well. The latter show no evidence of *congenital syphilis.*

On admission to the Royal Victoria Infirmary, Newcastle-on-Tyne, on May 18th, 1925, an oval ulcer, measuring 1 in. by 3/4 in., posterior to the internal malleolus of the left foot was present; the skin edges were smooth, and its base was granulating, but covered with *purulent exudate. The ulcer was superficial, and did* not extend deeper than the subcutaneous tissue. The skin in the vicinity was pigmented, and showed numerous depigmented scars of previous ulceration. A similar appearance of healed scars was present in the right leg; the left great toe showed a condition of moist gangrene, limited to the toe.

The lower third of the left leg and foot were colder to touch than the rest of the leg, and on allowing the leg to hang down an erythematous blush developed rapidly over the inner border and dorsum of the foot, extending up to the ankle, thus giving the foot the appearance of typical *erythromelalgia. The foot was* most comfortable when elevated and kept cool. No alteration in sensation was detected, and no loss of motor power. *No pulsation* could be felt in either anterior or posterior tibial arteries, and only faint pulsation over the popliteal artery. Later on no pulsation could be felt in this vessel. *The blood gave a strong* positive Wassermann reaction, and the urine contained no sugar. A radiograph taken on May 23rd, 1925, revealed nothing of note in either leg. No evidence of tuberculosis was found in the lungs or elsewhere in the body.

The patient was transferred to the surgical side of the hospital, and on June 25rd Mr. Pybus amputated the leg about a hand's breadth above the knee-joint. There was little bleeding from the stump, and recovery was uninterrupted. The lumen of the femoral artery appeared to be practically occluded.

When seen again nearly six months later (December 14th, 1925) pulsation was *present in the left femoral artery*, and the right foot had rather an erythematous blush over the dorsum and inner aspect, extending to the ankle; pulsation, however, was still present in the anterior and posterior tibial arteries. The patient complained of coldness of the foot, especially on standing, but not of pain. These symptoms appeared to point to an extension of the condition to the right leg. The arms had never been affected. Blood examination on this day revealed nothing noteworthy.

Red cells	4,535,000 per c.mm.
Haemoglobin	90 per cent.
Colour index	1
White cells	5,800 per c.mm.
Blood platelets	363,000 (that is, 100 to 1,250 red cells)

No increase in the fragility of the red cells was present.

Differential count (250 cells counted):

Polymorphonuclears	54.8 per cent.
Lymphocytes	37.2 ,,
Large mononuclears and transitionals...	6.8 ,,
Eosinophils	0.8 ,,
Basophils	0.4 ,,

No abnormality was found in the white or red cells in stained films. No nucleated red cells were seen.

Naked-eye Appearance of Amputated Limb.

Much difficulty was experienced in the dissection of the main vessels owing to the great degree of chronic inflammatory thickening in their vicinity, which caused the venae comites and nerves to be matted together. They appeared like fibrous cords in places. The popliteal artery was occluded by a greyish *ante-mortem* thrombus. The vein was markedly thickened but not thrombosed. Both anterior and posterior tibial arteries were completely thrombosed. The thrombus, especially towards the middle of these vessels, appeared to be organized. One of the venae comites of the anterior tibial artery contained some *ante-mortem* clot, but those of the posterior tibial did not. All the veins were thickened, and the surrounding structures were bound together by fibrous tissue, possibly from an associated periarteritis. The clot in the anterior tibial artery extended down to the commencement of the dorsalis pedis artery, the lumen of which was patent.

Histological Appearances of the Blood Vessels.

The affected peripheral vessels—the popliteal and anterior and posterior tibial arteries—showed completely organized thrombi in their lumina, some of which were partially recanalized. Marked histological changes occurred in all the coats.

The Popliteal Artery.—The vasa vasorum showed endarteritis obliterans (Fig. 1), and around them was distinct infiltration of cells of lymphocytic type, including definite plasma cells. The tissues in the immediate vicinity showed fibrous overgrowth. In the media a degree of fibrosis with interruption of the continuity *of the muscle and elastic fibres, dilatation of vasa vasorum*, and some lymphocytic infiltration was present. The internal elastic lamina was reduplicated in places, and interrupted by small thin-walled vessels passing into the clot. The intima was merged into clot by the process of organization. The thrombus, which occupied the whole lumen, was densely fibrous and completely organized. Between the fibres were deposited yellowish granules of altered blood pigment, and some of the newly formed capillaries had developed into quite large channels.

The Anterior Tibial Artery.—Sections were examined from the upper, middle, and lower ends of this vessel, and from one of its branches. The changes were more advanced in the upper end (Fig. 2), and were similar to those described in the popliteal artery. The wall of the vessel, however, showed much more fibrous thickening, and the vasa vasorum were more dilated. The periarteritis was more prominent. In the middle and lower ends, in addition to the appearances previously described, the adventitia showed a greater degree of cellular infiltration, and throughout the media were foci of epithelioid cells with pale vesicular nuclei and abundant protoplasm, and numerous multinucleated giant cells, with nuclei arranged around their peripheral parts (Fig. 3). These were external to the internal elastic laminae (Fig. 4). A marked degree of lymphocytic infiltration, especially around the vasa vasorum and at the margins of the foci, was present. The thrombus presented the same features as are described above, but just above the ankle-joint in a few places some small calcareous deposits were seen. There was also one large dilated vessel in the *clot; its wall, however, was composed only of endothelial cells.*

The branch of the anterior tibial artery showed a similar appearance to that described above, but no giant cells were seen. The thrombus appeared to have receded from the wall and permitted canalization to take place; some red blood corpuscles were present in its lumen.

No thrombus was present in the lumen of the anterior tibial artery at its junction with the dorsalis pedis artery. The adventitia only showed a slight degree of periarteritis; the vasa vasorum in media were distended, and only a slight degree of fibrosis was present; lymphocytic infiltration was not marked; the intima showed distinct fibrous thickening.

Sections taken from two separate parts of the posterior tibial artery, one higher up in the course of the vessel than the other, showed the lumen to be more or less closed by an organized *thrombus, in the centre of which was present a new channel.* The changes in the vessel wall were pronounced. The adventitia showed marked periarteritis with endarteritis obliterans of the vasa vasorum, lymphocytic accumulations, and occasional focal areas of epithelioid cells and scanty giant cells. The tissues in the vicinity were greatly fibrosed. While lymphocytic infiltration was present in the media, no giant cells were seen. The vasa vasorum were greatly dilated, and the muscle and elastic fibres much atrophied and replaced by fibrous tissue. The internal elastic lamina shows reduplication in places. The intima merged into thrombus, but appeared thickened by fibrous overgrowth. The thrombus had been completely organized by a cellular granulation tissue, and there was a large central opening present, which may possibly be due to recanalization, as in one of the sections it appeared to extend to the intima. This canalization extended almost the whole length of the vessel (Fig. 5). One of the branches showed marked intimal proliferation almost obliterating the lumen, and another branch was occluded by an organized thrombus similar to that previously described.

Sections from all the arteries, particularly where giant cell foci were present, were stained for tubercle bacilli, but, notwithstanding an exhaustive search, none could be detected. Other sections were stained by Levaditi's method for the detection of *Spirochaeta pallida*, but none were discovered.

Histological Appearances of the Veins.

The veins all showed some fibrous thickening of their walls, especially internal to the internal elastic lamina (Fig. 6). Lymphocytic infiltration and endarteritis obliterans of the vasa vasorum were not marked. The popliteal vein and venae comites of the posterior tibial artery were not thrombosed, but one of the venae comites of the anterior tibial artery contained a thrombus composed of fibrin, leucocytes, and red blood corpuscles, which showed early organization at one point.

Histological Appearances of the Nerves.

Both the anterior and posterior tibial nerves were the seat of perineural fibrous thickening, and the fibrosis extended between the various nerve bundles and between individual nerve fibres which appeared atrophied. In places fat could be demonstrated in the nerve fibres.

While the symptoms and appearances described in this case are identical with thrombo-angiitis obliterans occurring in the young subject, syphilis apparently plays no part as an ætiological factor in that disease, and no spirochaetes have been demonstrated (Buerger).[1] In Perla's[2] series of 41 cases 36 gave a negative Wassermann reaction. The term "thrombo-angiitis obliterans" was first employed in 1908 by Buerger, who gave a detailed description of the disease from an examination of 38 cases, but it has been described under various names—such as pre-senile gangrene, non-syphilitic obliterative endarteritis of the Jews, obliterative endarteritis of the young, and endophlebitis and endarteritis, etc., by many of the earlier writers. Russian, Polish, and Rumanian Jews, it is said, are most generally affected. Perla found 41 cases, all Jews, out of 10,000 cases in the records of the Montefiore Hospital, New York, but states that no conclusion can be drawn from this, as 95 per cent. of all the patients there are Jews. Other authors have reported cases among Turks, Chinese, Koreans, and Japanese. The average age of onset is about 30 years, and all the recorded cases have been males; 10 of Perla's cases were tailors. Buerger found the left leg the first to be affected, but Perla the right leg in the largest number of his cases. All the limbs, however, may be affected. Perla described a case occurring in the aorta and coronary arteries as well as in the peripheral vessels of both legs. The disease in all cases originates in the smaller vessels, such as the dorsalis pedis artery, and ascends to the vessels above. The capillaries of the extremity remain free. Professor C. F. M. Saint of Capetown University informs us that he has seen a considerable number of these cases in South Africa in recent years; in certain cases the disease involved both upper and lower extremities.

The histological appearances of the present case show a condition of thrombo-angiitis obliterans with an associated phlebo-sclerosis or phlebo-thrombo-sclerosis, which would appear, in view of the positive Wassermann reaction and the exclusion of other causes, to be of syphilitic nature. Tuberculosis is reasonably excluded from the absence of tuberculous lesions elsewhere. There was no evidence of a generalized miliary tuberculosis or of a tuberculous lesion in the immediate neighbourhood from which direct infiltration could arise. As has already been stated, no tubercle bacilli were detected in the lesions. Such extensive giant cell formation as was present in our case is uncommon in the smaller arteries in syphilis. Buerger described giant cell formation as occurring in the intima, internal to the elastic lamina, and also in the thrombus, and regarded these cells as probably phagocytes assisting in the process of organization. No giant cells were present in any of Perla's cases. It is possible that some of Buerger's cases were of syphilitic origin, as no Wassermann tests were performed, the disease having been excluded on the ground that no spirochaetes were found.

The condition is distinguished from gangrene due to injury, with resulting thrombosis, and thermal gangrene following prolonged exposure to extreme cold, by the fact that these develop in forty-eight hours. The absence of sugar in the urine excludes diabetic gangrene. In arterio-sclerotic endarteritis obliterans the vasomotor phenomena, blanching and hyperaemia, are infrequent, and gangrene supervenes early and progresses more rapidly. Again, physical manifestations of impaired circulation are few prior to the onset of gangrene. Raynaud's disease is distinguished by its sudden onset with local syncope or regional ischaemia, involving the fingers, more rarely the toes and other parts; by short duration of sensory and vascular manifestations; their intermittent character and absence of arterial occlusion between the attacks.

The changes in the vessel walls in the present case would account for the thrombus formation with all the other related symptoms, gangrene, etc., and the sclerosis of the nerves for the atrophic disturbances. The feature of such cases is the slow progressive thrombus formation, with periods of remission of symptoms and the comparatively late onset of gangrene.

We have difficulty in accepting Buerger's view of a primary thrombosis with secondary change in the vessel wall. It seems more probable that the toxic agent which has caused the condition set up the changes in the vessel wall primarily and that the thrombosis occurred secondarily. No doubt when existing thrombosis has altered the current of blood in an artery abnormal eddies may precipitate thrombosis in other parts of the vessel where there may be no obvious disease in its walls.

The thrombosis in the present case would appear to have originated in the popliteal artery and to have spread progressively downwards to the anterior and posterior tibial arteries, rather than to have ascended from below.

Perla agrees that luetic endarteritis, leading to occlusion of the peripheral arteries of the extremities, while rare, can only be distinguished from thrombo-angiitis obliterans by the presence of other evidences of syphilis.

LIPIODOL IN PULMONARY DIAGNOSIS: ITS USES AND LIMITATIONS.

(With Special Plate.)

BY

F. G. CHANDLER, M.A., M.D.CANTAB., F.R.C.P.LOND.,

PHYSICIAN (WITH CHARGE OF OUT-PATIENTS), CHARING CROSS HOSPITAL, AND TO THE CITY OF LONDON HOSPITAL FOR DISEASES OF THE HEART AND LUNGS, VICTORIA PARK;

AND

J. M. YOUNG, M.B., CH.B.N.Z.,

LATE HOUSE-PHYSICIAN TO THE LATTER HOSPITAL.

LIPIODOL, a compound of iodine and oil (poppy seed) introduced as a diagnostic aid by J. Forestier, is non-irritant to the tissues of the body and opaque to the *x* rays[*]; when injected into the bronchial tree it will flow to the utmost limit of the ramifications and fill the alveoli, rendering both opaque and clear cut. It might be thought, therefore, that by its use bronchiectatic and emphysematous dilatation would be seen, lung cavities demarcated, the position of lung abscesses determined, the site of a broncho-pleural fistula demonstrated, and the existence of a foreign body in the bronchus or a tumour shown; that we should be able to distinguish between an abscess, an old empyema cavity with a fistulous opening into the lung, and bronchiectasis—a problem which not infrequently confronts us; we might also expect to diagnose with greater ease conditions which are notoriously difficult in the early stages—such, for example, as new growths—and be able to assess the significance of the constant clicking basal râles that from time to time puzzle us. How far this expectation has been realized we shall endeavour to show by the cases described below. We have injected lipiodol in over fifty cases at the City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, and it will be seen that while in some instances information of great value was obtained, in others no help was given; or the information obtained was sometimes of a negative character, by which is meant that the examination with lipiodol having excluded bronchiectasis we are driven to search for other conditions which give rise to a similar clinical syndrome.

Methods of Injection.

Several routes for injecting the lipiodol have been used by different workers: (1) through the crico-thyroid membrane; (2) through the trachea below the isthmus of the thyroid gland; (3) the bronchoscopic route; and (4) the transglottic, by means of a laryngeal syringe; a rubber tube extension is sometimes employed, or a weighted catheter which can be passed into the right or left bronchus at will. We have used the first method almost exclusively.

Technique.

A. *Apparatus.*—(1) A 20 c.cm. glass syringe. (2) A special needle made by Allen and Hanburys (bluntly bevelled, 3/4 in. in length, No. 15 Birmingham wire gauge), or a small trocar and cannula which has been made for us by the same firm,† with a bore of one millimetre only, which is quite sufficient to permit the passage of the oil; or the curved trocar and cannula used by Dr. Armand Delille, like a minute tracheotomy tube, which can be fastened in position by tapes round the neck. (3) Syringe and needles for novocain and cocaine.

B. *Lipiodol.*—Temperature raised to 100° F. by immersing the metallic container in hot water. This decreases the viscosity, and allows the oil to flow easily.

C. *Patient.*—(1) Cocaine idiosyncrasy should be tested beforehand by giving an eighth of a grain of cocaine either subcutaneously or by mouth. (2) No food for three hours before the injection. (3) Morphine for adults (one-sixth of a grain hypodermically); tinct. camph. co. in the case of children is perhaps advisable if cough is troublesome. (4) The patient is propped up by pillows over which the head is extended in order to expose the crico-thyroid region. The operator stands on the right side of the patient. (5) The site is prepared with spirit or ether, and not with iodine, as this is opaque to the *x* rays.

D. *Anaesthesia.*—(1) A few minims of 2 per cent. novocain are injected intradermally over the crico-thyroid space (larger quantities may obscure the landmarks). (2) Into the trachea 0.5 c.cm. of a 5 per cent. solution of cocaine is injected, a stouter needle being used to avoid the possibility of the needle breaking should the patient cough. The thyroid cartilage is steadied by the left hand, and the needle inserted through the crico-thyroid membrane. To make sure that the needle is in the larynx air should be drawn into the syringe. The cocaine is then injected slowly, but should the patient cough it must be injected quickly, and the needle rapidly withdrawn.

E. *Injection of Lipiodol.*—Having filled the syringe the needle is introduced through the crico-thyroid membrane. The piston is then withdrawn, and air should enter freely. This test is essential, and should be repeated during the injection. The position of the patient may now be altered according to the part of the lung to be injected. If this is the right lower lobe the above position is satisfactory, as the lipiodol tends to gravitate into the right bronchus; if the left side, the patient should be placed gently inclined to the left; if the apex, the patient should be breathe deeply through the mouth and to suppress swallowing movements and cough. We have injected between 15 and 20 c.cm. of lipiodol as a rule. The procedure should take about five to ten minutes. After the injection any lipiodol on the skin should be wiped off with ether, a collodion dressing applied, and the patient should be radiographed as quickly as possible, both in the horizontal and vertical positions. The manipulation of the patient should be gentle, as otherwise coughing may be induced and part of the lipiodol may be dislodged before an *x*-ray picture has been obtained.

Effect on the Patient.

Using, as we have done, a very small amount of cocaine solution there is very little, if any, discomfort. Sometimes there is a feeling of constriction; this is relieved by a sip of water. The injection of the oil appears to cause no discomfort, but the patient may complain occasionally of the taste and smell of the lipiodol. In sensitive subjects the symptoms of iodism may occur. This happened in one of the Victoria Park cases, when a characteristic rash appeared. In another case an attack of asthma seemed to be precipitated. Apart from these we have seen no harmful effects, although over fifty injections have been made.

The Normal.

A knowledge of the normal picture is obviously the first essential. Figs. 1 and 2 we consider normal.

The following are illustrative cases.

CASE I.—*Early Bronchiectasis.* (Fig. 3.)

A girl, aged 12, who had been treated for two or three years as a case of tuberculosis owing to cough, expectoration, and haemoptysis, and abnormal signs over the right upper lobes; tubercle bacilli, however, were never found in the sputum or the faeces. Lipiodol injection showed the condition to be bronchiectasis.

CASE II.—*Gross Bronchiectasis.* (Fig. 4.)

A woman, aged 26, when between the ages of 6 and 8 had pneumonia on three occasions. At the age of 9 she was treated in hospital for bronchiectasis. On the present occasion she was admitted complaining of increased cough and sputum since an attack of "congestion of the lungs," eighteen months previously. Her fingers and toes were clubbed. She was expectorating 12 to 20 ounces of offensive sputum in the day. A radiogram showed a large dense shadow at the right hilus, and an opacity above the inner part of the right diaphragm. The bases were fairly clear. Two lipiodol injections were given; Fig. 4 shows the picture after the second. Large masses of lipiodol are seen at both bases, and the gloved finger type of bilateral bronchiectasis revealed.

† Latterly one of us (F. G. C.) has used this trocar and cannula exclusively.

CASE III.—*Bronchitis and Emphysema.* (Fig. 5.)

A man, aged 29, was severely gassed in 1917, and had since complained of recurrent attacks of bronchitis. The chest was barrel-shaped, and there were signs indicative of bronchitis and emphysema. No tubercle bacilli were found in the sputum. A radiogram showed increased striations at the right base. An injection of 18 c.cm. of lipiodol was given through the crico-thyroid membrane. Fig. 5 shows abrupt terminations of the outline of several bronchi and a peculiar flocculent distribution of lipiodol in the alveoli.

CASE IV.—*Chronic Lung Abscess.* (Fig. 6.)

A boy, aged 12, was sent by Dr. Trower to Charing Cross Hospital. He had had pneumonia at the age of 6, and since then had always had a cough. Three months before admission he had "influenza," and since this illness the cough had become more troublesome and the sputum had increased and had become offensive. The fingers were clubbed. Anteriorly the right side of the chest was impaired to percussion, and the breath sounds were harsh but distant. Posteriorly similar signs were obtained over a more limited area below the angle of the right scapula. The daily sputum amounted to 10 ounces, and had an exceedingly offensive odour. No tubercle bacilli were found, although repeated examinations were made. A radiogram showed an opacity in the mid-zone and base of the right lung. Towards the outer part of the centre of this shadow there was a circular area of lesser density. Lipiodol was injected. This went almost entirely into the left lung, and showed a normal bronchial and alveolar outline. Bronchoscopy was therefore performed by Mr. Davis, and an attempt made to fill the right bronchial tree with lipiodol. Again it failed, but Fig. 6 shows the substance outlining the bronchi up to the diseased area, but going no further. The injection thus excluded bronchiectasis, but failed to differentiate between pulmonary abscess and empyema with a broncho-pleural fistula. The case, however, seemed to be one urgently demanding operation. This was done by Mr. Clogg, and a large pulmonary abscess cavity was found, which was successfully drained.

CASE V.—*Empyema Cavity with Broncho-pleural Fistula.*

We were anxious to know if lipiodol would demonstrate a broncho-pleural fistula. A case of old chronic empyema of three years' standing was therefore taken, in which 20 ounces of offensive pus had been coughed up one week before admission to hospital. The lipiodol did not appear, in this case, to enter the old empyema cavity.

CASE VI.—*Contracted Left Lung. ? Pressure on Main Bronchus.*

A man, aged 49, had had repeated attacks of malaria and bronchitis; he had lost 2 st. in weight. He was admitted with bronchitis and bronchopneumonia, and the heart was displaced to the left. After the acute attack subsided he was left with dullness all over the left side, with bronchial breathing, and absence of adventitious sounds. The heart was in the left axilla. The *x*-ray picture showed a dense opacity all over the left side, with the right lung invading the left side of the thorax and the heart drawn to the left axilla; it gave no clue to the cause of the condition. The Wassermann test was strongly positive. The diagnosis of pressure on the left main bronchus by aneurysm or gumma suggested itself, and lipiodol was injected in the hope that further light would be thrown on the case. A very interesting picture was obtained. Through the opacity could be seen the denser shadow of the lipiodol; the main bronchus appeared to be immensely enlarged, as though flattened out; the bronchi springing from this were enlarged and blunt-ended; they appeared to be uniformly enlarged, but with no bronchiectatic dilatations, and ended abruptly without any of the usual alveolar arrangement of the lipiodol.

CASE VII.—*Diabetes and (?) Neoplasm of Lung.*

A man, aged 54, was admitted with diabetes, cough, occasional haemoptysis, and pain over the right side of the chest, which had been present for two months. There was slight clubbing of the fingers and dullness on percussion at the right base and absent breath sounds, but no adventitious sounds. There were no tubercle bacilli in the sputum. The radiogram showed a vague shadow, suggesting a possible growth. Lipiodol, however, freely entered this dull "silent" area and had a normal distribution, thus giving no help in the diagnosis.

CASE VIII.—*Bronchiectasis.*

A man, aged 53, in 1921 suddenly coughed up half a pint of stinking pus and collapsed. From this he recovered. In January, 1926, he again coughed he had a large haemoptysis. He was brought to hospital; the chest was up pus and fainted. He was obtained, and an operation for explored; a little pus was performed. No empyema was discovered. A little empyema was injected, and a bilateral bronchiectasis was later lipiodol revealed.

The Positive Findings.

In bronchiectasis we get positive evidence of dilatation of the bronchi. The picture appears to be pathognomonic and unequivocal (Figs. 2 and 3). It is the only positive method of proving the diagnosis. It is well known that, as a rule, the ordinary radiogram gives little help in diagnosing bronchiectasis. Either very little can be seen,

or the shadows thrown are similar to those obtained in many different pathological conditions, or the lesion may come behind the heart shadow. The first two points are demonstrated in Case I. Here the physical signs were like those of chronic tuberculosis, and the radiogram could be interpreted in various ways. Lipiodol injections proved the condition to be bronchiectasis. Frequently constant clicking râles are heard at one or both bases. If these are due to bronchiectasis we believe that proof positive can be obtained by the use of lipiodol.

Lipiodol will flow into a tuberculous cavity and outline it or fill it; but as a rule such cavities are obvious on the ordinary radiogram. It would be of value, however, in differentiating a large superficial tuberculous cavity from a localized pneumothorax. We have avoided injecting tuberculous cases as far as possible owing to unfavourable reactions having been reported.

Limitations.

Is there any other picture obtained after lipiodol injection which can be considered unequivocally pathognomonic? The answer is doubtful. Fig. 5 shows the picture obtained in a case of apparent chronic bronchitis and emphysema, and it is in accordance with the appearance described by the French writers on the subject. Frequently the information obtained is of a negative character. In cases of lung abscess and old empyema cavity it has been our experience that the lipiodol stops short at the periphery of the diseased area. This is shown in Fig. 6 (Case IV). We have seen the same thing in other cases.

Apparently, therefore, it would not help us to distinguish between a superficial non-tuberculous lung cavity and a localized pneumothorax, or between a pulmonary abscess and an old empyema cavity. What is obtained, however, is the knowledge that bronchiectasis does not exist, and this may be of value both in diagnosis and treatment. In Case IV lipiodol was also injected through the drainage tube into the abscess cavity; it outlined the lower part of the cavity, and this was all. None appeared to go through the bronchi.

We have injected lipiodol in cases of new growth of the lung, old empyema cavity, tuberculosis, and other conditions mentioned above, but apart from the filling of a tuberculous cavity no special help was given, nor did we obtain what may be called a pathognomonic picture. By this we do not mean to suggest that the method has failed. With an enlarged experience, both in the number of cases and in interpretation, more knowledge may be obtained. It would seem that a distortion or misplacement of a bronchus ought to be made manifest. All that we say is that, except in the cases mentioned, we have not hitherto obtained any strikingly helpful radiograms. Case VI, however, certainly gave a distinctive picture, but though tending to confirm a tentative diagnosis based on inferential reasoning, it did not give positive evidence of the actual underlying cause of the condition.

Summary.

1. Lipiodol injection will apparently enable us to diagnose and localize bronchiectatic dilatations with certainty: moreover, in many cases it is the only method of proving the diagnosis.

2. It enables us to distinguish bronchiectasis from lung abscess, from empyema with a broncho-pleural fistula, and from tuberculosis.

3. With regard to the diagnosis of lung abscess and empyema with a pleural fistula, the help is of a negative character. The lipiodol does not appear to enter the pulmonary abscess, but stops short of it; nor does it easily flow through the bronchial fistula into an empyema cavity.

4. Tuberculous cavities fill readily, but it has been suggested that injections are undesirable in cases of pulmonary tuberculosis.

5. In our opinion the method described is simple and harmless, giving invaluable help in certain cases, but possessing limitations.

We are indebted to Drs. Leggett, J. V. Sparkes, and Russell Reynolds for the skiagrams, especially to Dr. Sparkes, by whom most of the radiological work was done.

Fig. 5.—Chronic bronchitis and emphysema. Case III.

"VOLVULUS NEONATORUM."

BY

NORMAN M. DOTT, F.R.C.S.Ed.,

SURGEON, ROYAL EDINBURGH HOSPITAL FOR SICK CHILDREN; ASSISTANT SURGEON, CHURCH OF SCOTLAND DEACONESS HOSPITAL.

THE following case appears worthy of record, as it is, so far as I know, the first of its kind to be recognized from clinical observation and to be successfully treated by operation. The case was one of the disease which I described in 1923 as "volvulus neonatorum."[1] In this condition the normal rotation of the midgut fails to occur during development. In consequence of this the mesentery fails to acquire its secondary attachment to the posterior abdominal wall, and the entire small intestine and right half of the colon depend as a mass from a narrow pedicle at the origin of the superior mesenteric artery. The condition obviously predisposes to a volvulus of this enormous extent of bowel. The accident usually occurs within a few days of birth—probably as a result of the first peristaltic efforts of the intestine in response to feeding. The volvulus is peculiar in that the third part of the duodenum is acutely obstructed by being tightly twisted round the pedicle while the less fixed colon does not suffer. Since the involved bowel has a free exit below through the colon, it does not become distended, but collapsed. The blood supply is but slightly impaired, causing only a moderate cyanosis of the intestinal coils.

Of the diagnosis I wrote as follows:

"In these cases I think a correct diagnosis is . . . possible . . . The child is apparently normal when born and remains so for some days. Meconium is passed, and if the onset of the volvulus has allowed time, food residue appears in the motions in due course on the third or fourth day. With the onset of volvulus there may be shock, though this was observed in one case only. Vomiting begins early . . . The vomit is soon deeply stained with bile, for the obstruction lies below the duodenal papilla. . . . The upper half of the abdomen becomes distended by the stomach and duodenum, while the lower part becomes recessed from collapse of the intestines. . . . Melaena may or may not be evident."

It was pointed out that the above syndrome defined the condition clearly from all other possible causes of alimentary obstruction of the first few weeks of life. It was suggested "that reduction of the volvulus would be the most hopeful line of treatment. The intestinal mass would have to be delivered and untwisted."

A female infant, aged 8 days, was admitted to the Royal Edinburgh Hospital for Sick Children on May 20th, 1926, having been referred to us by Dr. Sharp of Musselburgh on account of intestinal obstruction. The birth was natural. Abundant meconium passed. Natural light yellow food residue appeared in the motions on the third day, and a normal motion was passed on the morning of the fourth day. The baby took the breast well until the fourth day, when she had a sudden fit of crying, holding the breath, drawing up the legs—apparent abdominal pain. There was no pallor. From this time she refused to suck. She vomited with increasing frequency, at first clear fluid, then yellowish, and latterly dark green flaky material. There had been complete constipation. There was little further pain until the morning of admission, when it seemed to recur and persist. On the morning of admission a small quantity of blood-stained mucus was passed per anum.

Examination.—A well developed infant; the eyes sunken, the mouth dry, the face drawn, and the skin generally lax and folded from rapid dehydration. A severe degree of toxaemia was obviously present. The upper part of the abdomen was prominent from gastric and duodenal dilatation, the lower part was flat. Small quantities of dark green flaky material were regurgitated at intervals of a few minutes. The rectum contained traces of blood-stained mucus.

Provisional Diagnosis.—From the clearly defined sequence of events of the history, and the facts observed on examination, a confident diagnosis of "volvulus neonatorum" secondary to an error of intestinal rotation and fixation was made. It will be noted that this was based on evidence of acute obstruction to the duodenum below the bile papilla and of post-natal origin.

A large continuous subcutaneous infusion of glucose-saline solution was administered, operation being postponed for four hours in order to re-establish the fluid and carbohydrate equilibrium.

Operation.—Ether anaesthesia. Right paramedian incision. The stomach and duodenum were enormously distended with fluid and gas, the pylorus being widely dilated. The distension ended abruptly where the third part of the duodenum crossed in *front* of the superior mesenteric vessels and was sharply twisted round them in a clockwise direction. In this case the caecum had crossed the mid-line from left to right and was loosely adherent over the right kidney (incomplete or "mal-rotation"). The lowest coil of the ileum with its free mesentery was loosely

wound around the pedicle of the volvulus and was free from constriction. The entire jejunum and ileum were implicated in the volvulus. They presented an extraordinary appearance, being *deeply cyanosed, quite collapsed and empty, and massed into* a compact bunch, which depended freely from the narrow pedicle of the superior mesenteric axis. The mass of congested, collapsed bowel could be most accurately likened to a conglomeration of bluish earthworms. The mass was rotated in an anti-clockwise direction through about 360 degrees. A few light, recent adhesions were present about the constricted portion of the duodenum; these were readily separated and permitted the organ to come into its natural position behind the mesenteric root. So soon as the constriction of the duodenum was relieved by untwisting the volvulus, the gaseous and fluid contents of the dilated stomach and upper duodenum passed rapidly down the jejunum and had entered the ileum before the bowels could be returned to the abdomen. Since the infant was seriously ill from four days of acute duodenal obstruction, it was thought unwise to prolong the operation by fixing the replaced intestines. It was hoped that this would occur naturally in the course of post-natal development. The abdomen was closed. The operation had been a very easy and rapid one.

Progress.—No further vomiting occurred, and the infant took the bottle well within three hours of operation. An uninterrupted convalescence ensued and she was discharged from hospital on the fourteenth day. She has been seen at regular intervals since. She has progressed quite normally; there has been no vomiting, no evidence of abdominal pain, and a steady gain in weight. At the last report (November 23rd, 1926) the child appears a particularly robust little girl of 6 months, weighing 12 lb. 12 oz.

I regard this case with peculiar satisfaction, as it represents to me the outcome of former embryological and pathological researches in practical diagnosis and operative cure.

HAEMATURIA FOLLOWING INSULIN INJECTIONS.

BY

JOHN HENDERSON, M.D., CH.B., F.R.F.P.S.G.,

VISITING PHYSICIAN TO GLASGOW ROYAL INFIRMARY.

IN 1923 and 1924 I noted several cases of diabetes mellitus in which the use of insulin injected in the usual manner was associated with a transient haematuria. I could not trace any records of similar cases, and on inquiry of other physicians who had a large experience of insulin administration I did not get any corroborative information. While noting the facts I decided to await further confirmation, as apparently the occurrences were simply coincident and of no serious moment. Since then, over many hundreds of similar injections in private and hospital practice, and in many cases with large daily doses, I have never met with a similar experience. I have also been watching the literature of the subject for any reference to the occurrence of haematuria in similar circumstances, but without avail till in the *Epitome* of the BRITISH MEDICAL JOURNAL of October 23rd, 1926 (para. 364), I found J. Güdemann reported as having described a case of haematuria following insulin treatment. As the history of the case was there given it need not be repeated here. Güdemann referred to two other cases, and stated that all his own cases of haemorrhage after insulin treatment occurred in a period of four and a half years; he thinks it probable that haemorrhages after insulin treatment occur more frequently than has been believed hitherto.

As such occurrences have not apparently been noted in this country I wish to refer to three cases, in all of which a very transient haematuria was observed.

CASE I.

A boy, aged 13, was admitted to my ward on October 23rd, 1923, in a state of coma, and on that day he had 20 units of insulin on two occasions. He made a rapid recovery from coma, and next day felt very well, though he had very decided haematuria. Microscopic examination of the urine showed, in addition to blood corpuscles, a few hyaline casts. The haematuria cleared up completely within twenty-four hours, and did not recur, though he had regular daily doses of insulin during the remainder of his residence. He is still under regular supervision at intervals, and though regular doses of insulin have been given, no similar occurrence has been observed. He is well developed and sturdy.

CASE II.

A man, aged 32, with advanced diabetes, had three attacks of haematuria during one month. He started insulin treatment in my ward on September 20th, 1923, and was at one time having 50 units daily. He developed severe haematuria on October 30th, and had recurrences on November 5th and November 27th. On each occasion the attack persisted for a few days, was not associated with any discomfort or signs of kidney disease, and cleared up completely.

CASE III.

A man, aged 59, had marked diabetes, requiring a daily dose of 40 units over a prolonged period. In May, 1924, in a nursing home, he had an attack of haematuria lasting twenty-four hours. Here also there were no associated symptoms of renal disease, and no feelings of discomfort.

I am tempted to add a fourth case of haemorrhage in similar circumstances, though it was not haematuria.

The patient was a man, aged 73, who had suffered from diabetes for some time, but had not had insulin. When I saw him with his doctor on June 8th, 1924, he was on the verge of coma and became comatose before he reached the nursing home. With insulin in considerable doses he recovered consciousness completely, but four days thereafter he had a cerebral haemorrhage, with resultant hemiplegia, and died.

These cases all occurred within a period of about eight months, and, it is of interest to note, rather earlier than those referred to by Güdemann. I have no explanation to offer as to the cause of such haemorrhage, as the conditions of administration of the drug were at all times as nearly as possible the same, and, of course, in the cases in the ward others were having the same insulin without any haemorrhage. It would be interesting to know if other examples are on record of similar occurrences during insulin administration.

STUDY OF AN ANAEROBIC STREPTOCOCCUS.

BY

C. E. JENKINS, M.R.C.S., L.R.C.P.,

PATHOLOGIST TO SALFORD ROYAL HOSPITAL.

ANAEROBIC streptococci have been described before, and according to Douglas's observations they were sufficiently common in war wounds to render anaerobic culture of pus so obtained a matter of practical importance.[1] But the occurrence of these organisms in civil practice in England is sufficiently rare to justify record.

The streptococcus now described was isolated from an abscess in the lumbar region. The films showed chains of eight to ten cocci; no other organism was seen, and an examination for tubercle bacilli by the Ellermann and Erlandsen concentration method was negative.

Cultural Features.

A serum nutrient agar slope was inoculated, but no growth followed. As it was assumed that the inoculation was at fault a second slope was used, with a like result. The pus was then put on a "plain" agar plate and incubated anaerobically. A profuse growth was obtained in eighteen hours. The colonies were round, discrete, and about 0.5 μ in diameter. On inoculating a slope from this plate and incubating it aerobically no growth was obtained. The anaerobic subcultures grew well. An aerobic culture made from the fifth anaerobic culture showed a feeble growth in twenty-four hours which did not improve with further incubation. This was the only aerobic culture obtained, as attempts to repeat aerobic cultivation from later anaerobic subcultures have all failed. The addition of serum to the agar plates does not seem to influence the growth. In plain agar stabs and in gelatin at 22° C. the organism grows as a granular line along the length of the stab. The gelatin is not liquefied.

It should be explained that unless otherwise stated all further descriptions of growth and fermentative reactions refer to anaerobic cultivation.

The organism rapidly lost its chain formation in artificial cultivation, and so was tested in tomato extract media.[2] A tube of tomato broth was inoculated from a nutrient beef broth culture that showed clumps only in films made from it. Next morning a thick turbidity was present in the tomato broth, and a film showed nothing but chains of 12 to 16 cocci. The same result was obtained with a tomato slope, except that the chains were a little shorter. The thickness of the growth in the broth and on the slopes has since proved that tomato extract is much the best medium for cultivating the organism. The individual cocci do not show any great tendency to produce involution forms. The organism is, of course, Gram-positive.

Fermentative Reactions.

No gas was produced with any sugar, but the acid production, when obtained, was sharp, appeared within twenty-four hours, and did not change with further incubation up to five days. Acid was

produced in glucose, maltose, saccharose, lævulose, raffinose, salicin, inulin, dextrin, galactose, isodulcite, and arabinose. No change occurred in lactose, mannite, dulcite, adonite, sorbite, or inosite. Litmus milk was unchanged after seven days' incubation.

Ehrlich's rosindol reaction was negative when tested on a six-day nutrient beef broth culture. It was not possible to examine the reaction in peptone water as the organism does not grow in this medium.

The streptococcus does not haemolyse blood, nor does it appear to have any reaction upon neutral red. It is not soluble in bile.

Vitality.

The vitality of the organism is not great. It lives in tomato broth for about ten days and for seven days in beef broth. It is killed by exposure to a temperature of 60° C. for fifteen minutes.

It is well known that certain strains of the enterococcus exhibit a preference for anaerobiosis when first isolated, but the present organism differs from the former in several important particulars. Its sugar reactions bear no resemblance to Dible's typical strain[3] nor to any of the three variants. A further and more important distinction is that the enterococcus has great vitality and is thermo-resistant.

These facts, coupled with the ability to form chains, justify us in regarding the organism as a true streptococcus.

Its further classification presents some difficulty, as it does not conform exactly to any of the standard varieties. It approximates most closely to *Streptococcus equinus*, but it ferments raffinose.

Its preference for anaerobic conditions of growth seems to be fairly inherent and is not lost by artificial cultivation, if I may judge by the fact that, although a feeble growth was obtained from a culture made from the fifth generation of anaerobic cultures, the power was not retained or passed on in further generations of subcultures.

EXCISION OF LARGE ANGIOMA OF THE LIVER IN A DIABETIC.

BY

HERBERT H. BROWN, O.B.E., M.D., F.R.C.S.,

CONSULTING SURGEON TO THE EAST SUFFOLK HOSPITAL.

IT is becoming recognized that operations upon diabetics can be performed without undue risk, provided the glycosuria is in abeyance at the time of operation. I think that the following case may be of interest owing to the age of the patient, who had been suffering from diabetes for several years, the extensive nature of the operation, the absence of undue shock, and the uninterrupted recovery.

On June 17th, 1925, the patient, a maiden lady aged 76, was admitted under my care at a nursing home. She had been suffering from diabetes for several years, and the urine on a restricted, but not strict, diet contained at least 5 per cent. sugar.

She had a large hard globular myomatous uterus of about the size of a pregnancy in the sixth month, and what appeared to be a pedunculated myoma in the left hypochondrium. As she was suffering from considerable discomfort and pain in the lower limbs I had suggested that it might be advisable to remove the tumours. She was thin and looked frail, but was not emaciated. The specific gravity of the urine was 1040, and it contained 5 per cent. sugar. She was put upon a strict diet.

On June 19th the urine (sp. gr. 1020) contained a trace of sugar. On June 20th the administration hypodermically of 10 units of insulin once daily was begun. On June 23rd three doses of 10 units each were given. On June 24th the urine was quite free from sugar; insulin twice daily was begun. From this date to June 30th the urine continued to be free from sugar and the patient's condition was satisfactory.

Operation.

On June 30th, under chloroform anaesthesia as light as was possible, the abdomen was opened; the upper tumour was found to be a large dark purple lobulated mass attached to the lower edge of the left lobe of the liver by a peduncle of liver substance which was about 3½ inches broad and 1½ inches in thickness. The transverse colon was lying between the tumour and the big uterine myoma.

I removed the liver tumour by cutting through the pedicle and suturing the anterior to the posterior edge. The haemorrhage was very insignificant, only one artery in the middle of the pedicle had to be secured, and the excision was rapidly performed. I then removed the uterine myomatous mass by amputating through the cervix in the usual manner. The liver tumour, which was a cavernous angioma, weighed 1 lb. The myomatous uterus, which was partially calcified, weighed 3 lb. The whole operation took less than an hour. There was very little haemorrhage and no perceptible shock.

The patient had a fairly comfortable night, but vomited several times; she was given sips of water and weak tea. Next day she felt comfortable except for a tendency to vomiting; the urine contained 5 per cent. sugar, and was loaded with acetone; rectal saline and sodium bicarbonate were given. On July 2nd she was given feeds of water, coffee and toast, milk, diabetic bread, cauliflower, and 15 units of insulin was administered during the day. She felt much better; the sugar was much less, but the acetone was still abundant; there was no aceto-acetic acid. Next day milk was added to the diet, and on and after July 4th 15 units of insulin was given three times daily and more liberal diet. The acetone was much less. On July 7th she was allowed a fairly liberal diet, including custard, and mutton or sweetbread. Neither sugar nor acetone was present in the urine. Insulin was reduced to 12 units three times daily on July 9th, and this quantity was given twice daily. She left the nursing home eighteen days after operation. She felt well and comfortable, and the urine was free from acetone, but sometimes contained a little sugar.

The patient is now, eighteen months after the operation, in fairly good health, but as she is not careful about the diet the urine constantly contains sugar.

The tumour of the liver was a cavernous angioma of the kind described as due to dilatation of existing blood channels and atrophy of liver cells. These tumours may be multiple, but are more often single. The edge of the liver near the falciform ligament is not an uncommon situation, and they are sometimes pedunculated, as in this case. A microscopical section showed large intercommunicating cavernous spaces lined with endothelium and separated by fibrous tissue; no trace of liver tissue could be seen except in the pedicle.

Death has been known to occur from rupture of an angioma of the liver, and a few cases have been removed by operation. But the condition seems to be uncommon, though possibly less so than might be expected from the small number of cases recorded.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

AN OCCUPATIONAL SWELLING.

A PROFESSIONAL violinist was brought to consult me about a swelling below the angle of the jaw on the left side. It had been noticed for the last three or four years, and had increased slowly in size, but gave rise to no pain or discomfort.

The appearance of the swelling, which is shown in the accompanying photograph, suggested an enlargement of the tonsillar lymph gland. However, the enlargement was entirely due to a thickening in the subcutaneous tissues, adherent to the overlying skin, but freely movable over the deeper structures. It was firm, had no definite edge, did not fluctuate, and was not translucent. The overlying skin was normal, and there was no enlargement of the lymphatic or salivary glands on either side. The tonsils were small and healthy.

This is apparently a fibro-fatty pad developed in response to repeated pressure, analogous to that which is seen on the shoulders of deal porters. It is situated exactly on the area of skin which rests upon the edge of the violin when this is steadied between the angle of the jaw and the left clavicle. I have not seen a description of this condition.

W. H. OGILVIE, M.D., M.Ch., F.R.C.S.,
Assistant Surgeon, Guy's Hospital.

THE TEMPERATURE IN PULMONARY TUBERCULOSIS.

As there is some doubt whether the terminal temperature in pulmonary tubercle is tuberculous or septic, may I be allowed to quote three cases which appear to support the former view?

Case 1.—The most typical case of a swinging temperature I have seen was in the terminal stages of tuberculosis in a patient in the Royal Victoria Infirmary. The sputum was swarming with tubercle bacilli, whilst septic organisms were few.

Case 2.—An adult patient at the Stannington Sanatorium had a persisting subnormal temperature up to her death. Here the septic organisms were numerous, whilst the tubercle bacilli were few.

Case 3.—On September 18th, 1926, a man, aged 31, was admitted to the Harton Hospital, South Shields, with marked signs over the left upper lobe in front. The expansion was limited, the percussion note impaired, and marked pleural and pulmonary crepitations were present. He is losing weight, has a distressing cough, with abundant sputum, yet the temperature from September 18th to November 7th, night and morning, has been along the line of 97°. Only on nine occasions in seven weeks has it risen above 97°, and only once has it reached 98°. The respiration rate has averaged 24 night and morning, whilst the pulse rate has varied between 76 and 96. Dr. A. J. Slade reported on the sputum as follows: "Whilst the tubercle bacilli are one per ten fields, such fields contain cocci of pneumococci and staphylococci types which are too numerous to count."

The temperature of pulmonary tuberculosis would therefore seem to depend upon the numbers and activity of the tubercle bacillus, whilst the terminal temperature is probably due to excess of tuberculin or other products of the tubercle bacilli.

T. M. ALLISON, M.D.,
Visiting Physician to the Wingrove Hospital, Newcastle-upon-Tyne.

TRAUMATIC ULCERATION OF THE AORTA.

THE following case seems of sufficient interest to be placed on record.

A native woman, aged 28, was admitted to Omdurman Civil Hospital on June 3rd, 1926, complaining of pain in the region of the right lower chest, in which region she had been struck by her husband three days previously. She stated that the pain commenced shortly after receiving the blow; she "thought that she had swallowed a small bone" five days before admission to hospital. The only signs presented were some tenderness to pressure over the tip of the sixth rib, which was fractured, and slight dullness over the right base around the site of the blow. On June 5th the patient had a sudden haemoptysis and died. The Syrian medical officer informed the police, and the husband was placed under arrest.

Post-mortem Examination.—The base of the right lung was found to be congested, with marked discoloration at the site of the fracture. A meat bone, one square inch in size, was discovered impacted in the oesophagus at the level of the bifurcation of the trachea. The oesophagus in the immediate vicinity was grey-black in colour, and ulceration extended through its coats into the arch of the aorta. Death was due to haemorrhage following ulceration into the lumen of the vessel.

The case is of interest in that the woman, other than "thinking" that she had swallowed a bone seven days before her death, produced no symptoms indicative of the presence of a foreign body in the oesophagus. In view of the *post-mortem* findings the husband was, needless to say, released.

Khartoum. JOHN SIMONS.

MELAENA NEONATORUM.

THE following cases occurred in my practice here, and are of interest on account of the rarity of the condition.

A primipara, aged 30, at the beginning of February last gave birth to a particularly fine male child; it had been expected in November. On the day after its birth it vomited bright red streaks of blood, and the stools were noticed to be black and tarry. The child seemed extremely ill, and its condition looked so urgent that I administered 0.25 c.cm. of pituitrin, which seemed to act like a charm; the bleeding at once ceased and the child became well.

The second case occurred last October. A primipara, aged 37, gave birth to a healthy male child; on the fourth day thereafter signs of intracranial pressure appeared and the stools became black. The following *mixture* was given: gelatin 30 grains, sodium chloride 2 grains, water to 3 oz., 1 drachm every hour, together with 1 minim of adrenaline solution 1 in 1,000 every hour until three doses were taken, and then every two hours for another two doses. On the sixth day 10 c.cm. of blood were taken from the father's arm and injected intramuscularly; this was repeated on four successive days, when the child became well. This child was also expected six weeks earlier.

Stornoway. J. G. GRANT.

Reports of Societies.

THROMBO-ANGIITIS OBLITERANS.

AT a meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland on November 26th, 1926, Mr. R. C. B. MAUNSELL in the chair, Sir W. I. DE COURCY WHEELER read a paper on thrombo-angiitis obliterans, which is printed at page 225.

Dr. T. T. O'FARRELL showed a series of lantern slides illustrating the various points mentioned by Sir William Wheeler, and added that the trouble in this case had started in the great toe, and had spread upwards. The tissues were oedematous, and there was some exudation of blood. The upper part of the popliteal artery was normal, but the lower part was thrombosed. Most of the arteries of the limbs, with the exception of the peroneal, had fibrosis of the muscular coat, and several of the veins showed commencing calcification. Attempts at canalization of the clot were found here and there in the tibial vessels.

Mr. R. C. B. MAUNSELL said that he was interested in the suggestion made by Sir William Wheeler that possibly *very heavy cigarette smoking had something to do with* the disease; he personally thought that smoking was now too common a thing to be attacked and put down as the possible cause of any disease. Both the patients described had been Irishmen, but they had both been abroad; this suggested to him that the infection might be bacterial. He referred to a communication of a similar sort made to the Academy some years previously by Mr. Lane Joynt, but in this case the veins had been thrombosed all over the body.

Mr. C. J. MACAULEY asked if, in the first case described, the possibility of Raynaud's disease and peripheral gangrene had been considered, and, in the second case, whether the condition appeared simultaneously in the arteries, or if it had come first in one and then in another. He thought that the disease might have originated from an embolus, and asked how it differed from a thrombus, what was the average number of cases in which it occurred in both limbs, and what was the average time to be expected to elapse before recovery took place.

Mr. W. PEARSON referred to a case which he had treated about three years ago, and which was somewhat similar to those described by Sir William Wheeler. The patient was a farm labourer, aged 38, who previously had been perfectly healthy, who had never been abroad, and never smoked cigarettes, but always a pipe. The gangrene was dry, but spreading rapidly, and affected the left limb. Mr. Pearson performed a supercondyloid amputation, and the man had remained quite well ever since. The Wassermann reaction in this case had been negative, and there had been no sign of any arterial disease in any other part of the body.

Mr. H. S. MEADE referred to two cases of arterial gangrene which he had treated. One patient was a sailor, and a heavy weight fell on his toe, which was very painful, and later became black, when he was admitted to hospital. There was a definite red line of demarcation on the ankle-joint. Leriche's operation was employed, and post-operative relief from pain was immediate. The second patient was an old woman, aged 80, who had gangrene, and great pain. Leriche's operation was performed, and immediate relief followed; the date of the operation was nearly two years ago, and there had been no recurrence. Both these operations had been performed under *local anaesthesia*.

Sir WILLIAM WHEELER, in reply, said that in making the diagnosis embolism was discussed, but was not seriously entertained. In the first place, obstruction from an embolus might produce the symptoms described in a young man, but if the limb survived the first few days the collateral circulation would be rapidly established and all anxiety would have disappeared within the first fortnight. As a matter of fact, the circulation in the second case became more precarious daily for three weeks, until gangrene finally appeared. In the second place there was no discoverable lesion from which an embolus would come. The pathological examinations later proved the correctness

of this point of view, and established the fact that a true thrombo-angiitis obliterans existed. Raynaud's disease was difficult to exclude as a possible explanation of the first case. Nevertheless, Raynaud's disease commencing in the toes, in a strong man of 25 years of age, was exceptional, and the patient was the exact reverse of the type of individual in which the Raynaud syndrome was to be found. No pathological examinations were made, and he did not definitely exclude the possibility of Raynaud's disease. In the second case the diagnosis of thrombo-angiitis obliterans was certain. It was made before operation, and the pathological examinations were conclusive. He had had a fairly large experience of the Leriche operation. It produced many of the effects claimed, but the physiological reasoning on which the operation was based was open to criticism, and was not satisfactory.

Carcinoma of the Pelvic Colon Treated by X Rays.

Mr. H. S. MEADE showed a specimen of carcinoma of the pelvic colon, involving the bladder, from a woman aged 69, sent to him for cystoscopic examination in March, 1926. The clinical details were as follows.

The patient had been operated on twelve years previously for uterine prolapse. Last June she was in a motor accident and suffered from shock. Immediately after the accident she noticed that she was obliged to sit sideways when she wished to pass water. This passed off, but she still remained very nervous. At the time of examination she complained of frequency of micturition, with scalding pain. This trouble dated back a year and a half, and had been growing steadily worse, so that she had to pass water every hour both day and night. She had had medical treatment, but was not cystoscoped before she consulted Dr. Meenan. Albuminuria was present and a few leucocytes, but no sugar. An attempt to cystoscope her was unsatisfactory, owing to her nervous state and the small capacity of her bladder, which held half an ounce. Any attempt to dilate her caused extreme pain, but there was no sign of inflammation. The patient was kept in bed and gradual dilatation tried as she refused an anaesthetic at first.

Ten days after admission she was cystoscoped. The bladder dilated up to eight ounces easily, and examination showed no sign of inflammation except the congestion of the trigone so common in the female bladder. Chromocystoscopy with indigo carmine showed the dye coming from the right kidney in five minutes and from the left in four minutes. Before catheterizing the ureters a rectal and bimanual examination was made and a mass on the left side of the pelvis in the region of the left broad ligament was found. This mass extended above the brim of the pelvis and appeared to be well fixed. A sigmoidoscope was passed and a carcinoma of the pelvic colon was found.

Owing to the age of the patient, the fixity of the growth, and her terror of operation it was decided to treat her with deep x rays, and eight days later she received a full treatment, estimated by Holdfelder's field selector and calculated by Solomon's iontoquantimeter, and administered in two portions on successive days. The factors were: wave-length, A.U. 09; field, 12 by 10 cm.; focal skin distance, 30 cm.; filter 0.5 mm. with 2 mm. aluminium.

Irradiating from the front, one field was over the left Poupart ligament and the other over the right on the first day. On the second day one field was through the centre of the sacrum from the back, with two smaller ones on either side of it. The factors for the smaller fields were: 6 by 8 cm. at a focal skin distance of 23 cm. The exposure for the larger field was sixty minutes, and for the smaller one thirty-five minutes. The treatment was borne well, without radiation sickness or nausea. The dilatation of the bladder had relieved the frequency, which, however, returned in a milder form one week after the x rays, but passed off in a few days. The patient said that she was much better, and there was a definite shrinkage in size of the tumour. The irritability of the bladder returned three weeks later, but was relieved by bladder sedatives. Five days after this the deep x ray was repeated, reversing the fields with the same factors. No other disability followed the x-ray treatment, excepting the usual transient anaemia, which readily responded to haematinics, and a feeling of tiredness which lasted a few days. Ten days later the patient thought that she was passing gas from the bladder, so she had another cystoscopical examination; on the left upper lateral side of the bladder a small area of inflammation (1 cm.) was found, in the centre of which there was a pinhole fistula. There was no sign of any gas, or any evidence of faeces in the urine or the bladder. The patient, a fortnight later, was in great distress, passing large quantities of gas, especially on micturating, which was accompanied by a whistling sound that could be heard at some distance, and over which she had no control. It was decided that the best thing to do was to perform a colostomy to prevent the entrance of faeces into the bladder.

The patient was operated on under gas and oxygen anaesthesia, and on opening the abdomen it was found that the growth was lying on the left side of the bladder. The uterus was retroverted and atrophic. The left tube and ovary were fixed to the growth, and were oedematous, as was also the colon, the latter being reduced one-third in size. It was also more mobile, so it was decided to remove it. To do this it was necessary to remove over one-third of the bladder with it. The bladder was closed with three layers of sutures, and a muscle-splitting colostomy was performed. A catheter was inserted in the caecum for the introduction of saline, the abdomen was closed, the pelvis was drained, and a Poussin catheter was inserted in the bladder. *With the exception of a slight attack of phlebitis* in the third week, the patient made an uninterrupted recovery.

On opening the intestine a comparatively large, very soft and mucoid, tumour was found projecting from the bowel wall. Sections taken through the wall of the intestine, including part of the apparently normal mucous membrane, showed the following microscopical characters. The mucous membrane where present was comparatively normal, but at one place there was intense inflammation at its junction with the tumour. The new growth was composed of greatly distended and irregular glandular acini *filled with mucoid material*. The acini were found invading the muscle fibres, but mitotic figures were scanty. Throughout the muscle there was much chronic inflammation, and the surface showed distinct peritonitis of a subacute type. The specimen was a "colloid carcinoma," and in this case was associated with a considerable amount of inflammation. Sections taken through an adherent piece of bladder showed much inflammation, but no carcinomatous element could be found in this piece of material.

The patient reported later that she was, and had been for three months, in a splendidly healthy condition, appetite and digestion excellent, and sleep better than for years. All organs were acting normally, and the appliance gave very little trouble. She had put on over a stone in weight, and had completely lost her nervousness.

Mr. Meade said that the specimen was shown in the first place on account of the difficulty of diagnosis. Even when the growth was found the patient gave no definite symptoms of carcinoma. She had been constipated, passed some mucus and blood, and had some pain over the left side of the abdomen, but was rather indefinite about these signs. The second reason was the reduction in the size of the growth by the deep x rays, rendering operable a clinically inoperable case. Mr. Meade added that such growths might involve the bladder and a fistula be present; this should not deter from attempting their removal.

Clinical Cases.

Mr. MAUNSELL showed a girl, aged 17, who had a large tumour, practically filling the upper abdomen, depressed in the middle, and filled out on each side. It was dull, and appeared movable. By an x-ray examination a diagnosis of dermoid tumour was made. Mr. Maunsell opened the abdomen in the middle line, and found the stomach pushed up, and below the stomach huge veins crossing the tumour, and below the tumour was the colon. The tumour burst, and fluid came out. Mr. Maunsell then opened it freely, and found inside it a foetus, apparently attached over the right kidney, one limb being adherent over the aorta. It was growing between the two lairs of the transverse mesocolon. The uterus and ovaries were normal, and the girl made an uninterrupted recovery. He also showed a case of diffuse haemangioma of the liver in a man, aged 26, who had come to Mercer's Hospital in the middle of the night, last summer. Two days previously he had developed progressive weakness and abdominal pain. He became absolutely blanched; the distended abdomen was opened, and there pure blood was found. A bleeding point was looked for unsuccessfully, but the blood seemed to be coming down from the liver. Next day the patient was transfused; he did well, and after a slow convalescence he was allowed up, but never had a perfectly normal temperature. One day while up he again felt faint, and was put back to bed, and from then had a higher temperature. An x-ray examination showed that the diaphragm was higher on the right side than on the left, as in a case of subdiaphragmatic abscess. A needle was inserted, and bloody fluid withdrawn. A rib was resected, and only blood escaped. A tube was then inserted, and the patient apparently bled internally, and died.

Mr. C. J. MACAULEY referred to a case somewhat similar to the one described by Mr. Maunsell which had been brought before the Academy some years previously by Mr. Blayney, but in this case the haemangioma had not infiltrated so much through the liver as in Mr. Maunsell's case.

MOBILITY AND PROLAPSE OF THE ASCENDING COLON.

AT the last meeting of the Royal Medico-Chirurgical Society of Glasgow, the President, Dr. JOHN COWAN, in the chair, Mr. R. B. CARSLAW read a paper on the importance of undue mobility and prolapse of the ascending colon as a factor in the causation of various abdominal conditions, based on the results of 242 cases treated by colopexy.

Mr. Carslaw first showed lantern slides illustrating the various stages in the development of the intestinal canal and its mesenteries, the commoner bands and membranes found at different sites, and the chief anatomical features of importance; he also exhibited *x*-ray photographs of the appearances seen in normal persons, the commoner variations from normal, and the characteristic appearances in persons when the ascending colon is abnormally mobile. The anatomical results of this undue mobility were then summarized. The speaker referred to the two "types" of individual with faulty body formation who suffered commonly from the condition of prolapse—namely, the "virginal" and the "maternal." The clinical symptoms were discomfort after food, with more or less flatulence, passing into actual pain, which was characteristically variable and inconstant. Later, there was loss of appetite, increasing flatulence, and frequent bilious attacks, with headache, nausea, and malaise. Constipation might not be present at first, but was invariably present in the later stages. Finally, toxic phenomena appeared, such as progressive wasting, pigmentation of the skin, chronic mastitis, and, most important of all, mental changes. These symptoms occurred in groups, justifying the classification of the patients into clinical types, as, for example, "gastric," "*duodenal*," and "right iliac fossa." Mr. Carslaw considered that there was no such disease as chronic appendicitis, and emphasized the distinction between recurrent attacks of true inflammatory appendicitis and the condition of choked appendix, with appendicular colic, not accompanied by inflammation. Some authors had described "renal" and "biliary" types associated with attacks of renal and biliary colic, but in the speaker's series these symptoms were additional to the other symptoms, and the patients were not classified in a separate category. Mucous colitis and chronic duodenal ileus were mentioned as occasional late results. The relation of gastric and duodenal ulcer to prolapse of the ascending colon was briefly considered. Treatment was discussed under three headings: preventive, curative by suitable diet, laxatives and exercises, and operative. In Mr. Carslaw's opinion the correct operative procedure was to correct the undue mobility and prolapse of the caecum and ascending colon by Waugh's colopexy. In certain cases fixation of the caecum was sufficient, but in others not only must the whole ascending colon be fixed, but it was necessary to suspend the right half of the transverse colon as well. The restriction in the undue mobility seemed to him to be, perhaps, even more important than the correction of the prolapse. Division of any developmental membranes should also be performed, and if there was kinking of the gall bladder, with stagnation of its contents, it might be necessary to suspend or even to drain it, after division of its ventral membrane. The appendix, if present, was removed, except in those cases of severe mucous colitis, when an appendicostomy should be performed in addition to the colopexy. If there was marked hepatosis the correction of this might be helped by shortening the round ligament; the right kidney and the uterus should be left alone. After demonstrating a number of *x*-ray films showing the results of operation, Mr. Carslaw reviewed the clinical results of 242 consecutive colopexies performed between March, 1920, and July, 1926. In the great majority of cases the symptoms disappeared within a few months of the operation. The appetite, which had usually been very fickle, rapidly improved, and patients often reported their great satisfaction at being able to eat anything and everything. The relief from the distressing and often embarrassing flatulence was also greatly appreciated. The former bilious attacks, especially in the duodenal type of case, persisted for some months, but were much less frequent and severe. Although the characteristic pain, either after food or in the right iliac fossa, soon disappeared, in some cases a considerable degree of discomfort was felt in the right side of the abdomen; this worried the patient for about a year. The recovery from constipation, no matter how obstinate it might have been, was one of the most satisfactory results. A degree of constipation persisted, but as a rule the condition was absolutely cured. Another satisfactory result, noted in many cases, was the disappearance of menstrual irregularities; this occurred too frequently to be mere coincidence. There was usually a rapid improvement in general nutrition, with steady increase in weight, and the mental outlook was brighter. Of the 212 patients who were satisfied with their present condition, 44 were in his opinion not cured, although very much improved, as they still had some discomfort, occasional flatulence, some degree of constipation, or had failed to put on weight. The remaining 168 were absolutely cured, and that the cure was permanent could be seen from the number of years which had elapsed since the operation. Mr. Carslaw concluded by giving details of a number of the cases and of those classified as failures.

Mr. A. MCLENNAN said that he, in 1925, had performed colopexy, according to the method of Waugh, in 20 cases, but the reason for opening the abdomen had been that the appendix was suspicious. He believed that the appendix ought to be removed on suspicion, and he disagreed with Mr. Carslaw's contention that no such thing as a chronic appendix existed. The benefits which followed from colopexy were sometimes extremely striking. It was always difficult to explain the benefit which the fixation of the colon could achieve when the mechanics of the colon were considered. A remark about the dragging of the ascending colon upon the liver seemed rather absurd, because one of the clinical signs of ascites was that the intestine floated upwards. The weight of the ascending colon was a negligible quantity, and he failed to see how it could be an influential factor in the causation of duodenal ulcer, gall stones, or any other out-of-the-way disease. It had been thought that the kidney pushed the ascending colon down, but Mr. McLennan did not think that the ascending colon ever pulled the kidney down. He had been in the habit, since at least 1905, of fixing all caecums that he thought were excessively mobile. He had followed up several of the cases so dealt with, and he thought the procedure had resulted in considerable benefit. Another advantage was the obliteration of the intercolic membrane. Mr. Carslaw wanted them to believe that the drop in the ascending colon was the initial process in enteroptosis; it was an absence of muscular energy which followed the prolapse. He did not think Mr. Carslaw was correct in saying that children had highly placed ascending colons. A great deal had been made of the cause of most of the ills of humanity being the upright position, but Mr. McLennan thought the majority of the ills were due to the want of the upright position.

Mr. W. A. SEWELL thought that the practice of colopexy by Mr. Carslaw and others had been in a sense an experiment. It had been an attempt to find out whether Waugh's teaching was true, and whether by means of colopexy a cure might be found for the many and various symptoms associated with ptosis of the abdominal organs. Colopexy, like gastro-jejunostomy, colectomy, and even laparotomy, had had to run the gauntlet of criticism; it was often denounced most bitterly by those who had little knowledge of the operation beyond two or three cases. If critics would inform operators of their failures, much useful information would be obtained. In an inquiry of this kind a definite conclusion could only be reached by analysing a large number of cases over a considerable period of time. Since 1920 in the Victoria Infirmary Mr. Sewell had operated on, or been associated with Mr. Macrae in, 127 cases where colopexy had been performed. Of the 127 patients he had been able to trace only 69, and of

these 32 were perfectly well, 16 much improved, and 21 were failures, 4 of whom had died at a later date from acute meningitis, tuberculosis, excision of gastric ulcer, and cause unknown. He had deliberately treated two cases by colopexy where the pylorus was under suspicion, but a gastro-jejunostomy was required later and resulted in marked improvement. Some had criticized the operation because the patient had been diagnosed as a case of appendicitis; since the appendix was removed when the colopexy was performed, they argued that it was really the appendix which was at fault. Some of these patients were found on admission or at a later date to have an appendix normal in size and appearance; but in addition there was a large, loose caecum which could easily be pulled out of the wound. The true diagnosis in these cases was, in his opinion, a volvulus of this loose caecum. Those who followed their cases to the operation table must have seen the large, loose, mobile bowel and the apparently normal appendix. The removal of the appendix was an integral part of the operation of colopexy as described by Waugh, unless it had been removed previously. Lichty reported in 1923 on a series of 400 cases of "chronic appendicitis"; 225 were cured, therefore in 175 there had been a mistake in the diagnosis. Colopexy was not an alternative to gastro-jejunostomy for cases of pyloric ulcer, but it was an attempt to prevent the formation of ulcers, to remove the pull of the loaded ascending colon in that and other regions, and to cure the symptoms accompanying local and general visceroptosis. Mr. Sewell thought that colopexy undoubtedly lessened and often removed the pain associated with "floating kidney," and certainly restricted its movements. The results of the operation were by no means perfect, but they were encouraging, and the operation of fixation of the unduly mobile caecum and ascending colon was worthy of further investigation.

Mr. DONALD DUFF said that common dyspepsia, constipation, gastric ulcers, mesenteric ileus, and even dysmenorrhoea had been put forward as results of a mobile colon. Mobility of the caecum and ascending colon were normal conditions, and a fixed colon would be the abnormal condition. They had heard much about the presence of bands about the lower ileum and caecum as being of developmental origin, and Lane's ileal kink had been shown on the screen as one of these. Mr. Duff had had pieces of these bands removed at operation, and *B. coli* had been grown from practically all of them, proving that the bands were inflammatory in origin and secondary to constipation. A mobile caecum had been frequently discovered at abdominal operations, but every case he had seen of such a condition had also a last kink well developed. If developmental error was the cause of mobile colon, as claimed by Mr. Carslaw, it was curious that women should have been selected by Nature for the exhibition of this deficiency in the proportion of over 3 to 1, as stated in Mr. Carslaw's statistics. These figures, in fact, proved that the enlargement and mobility of the caecum were secondary to the constipation which was prevalent in the female sex, and due not to developmental error but to bad habits. Mr. Duff had been able in many instances to cure these cases of obstinate constipation by division of the bands alone without colopexy. Colopexy could not be adequately performed without division of Lane's bands, but it was the division of the bands and not the colopexy which produced any good result.

Mr. ROBERT TENNENT said he had been much impressed by the results of colopexy and by the benefits that had accrued therefrom. His own cases had nearly all been of the right iliac fossa type. Hardly a week passed in hospital without an urgent case being admitted labelled "appendicitis," the main symptom being pain in the right iliac fossa. In some cases these patients had been dismissed without operation, and later had been readmitted. On operating, it was invariably found that there was a very mobile caecum, and in these cases simple removal of the appendix would probably be nearly valueless. Appendectomy for so-called "chronic appendicitis" was useless if a mobile caecum were present. Mr. Tennent said he had traced about 60 cases where caecopexy had been performed, and he was very pleased with the results. He had rarely performed an exploratory operation with the idea of colopexy, but he had tried colopexy in cases where he had opened the abdomen for some other condition. In these cases he was convinced that the operation had been well worth while. He had also been struck by the fact that in the few cases of colopexy in males the results had been very unsatisfactory. In each of these cases the patient had probably suffered from what Mr. McLennan called defective innervation of the colon, for great dilatation was present. In such cases no beneficial results whatever had occurred. He thought that the point regarding the frequency of incidence of a loose colon in the male and female was explainable. A certain number of the women had had repeated pregnancies, which probably had an effect in loosening the colon. With regard to the transverse colon, Waugh's main point was that the ascending colon was the first part of the bowel which had to propel against the force of gravity. The transverse colon was in a better mechanical position for dealing with the contents than a mobile ascending part, which had a lot to do with chronic duodenal ileus. Mr. Tennent stated that he had seen several of Mr. Carslaw's cases at the second operation who, at the first operation, had had very marked duodenal dilatation; the correcting of the ascending colon had produced very beneficial results.

Dr. JOHN RITCHIE gave details regarding some thirty of his patients upon whom Mr. Carslaw had operated, and said that it was impossible to be apathetic or indifferent when the state of these patients before operation was contrasted with their present condition. Brief notes had been taken of nearly every case from time to time, going back in some instances to 1907. The patients fell readily into the groups referred to by Mr. Carslaw. Thus, some had pain at a varying period after meals, with flatulence, eructations, gurglings, and splashings. Some had pain a considerable time after meals, with attacks of vomiting. One had such severe pain that a pin-hole perforation of a duodenal ulcer was suspected. One had mucous colitis in addition to other symptoms. In some cases the pain was referred to regions other than the abdomen, as, for example, the heart, the back, the pelvis, and the leg. Many suffered from depression, sleeplessness, and obstinate constipation, and some had had previous operations. His notes in many cases extended over a considerable period of years, showing the patients to be never long off the sick list. He considered the results in practically all his cases to be most satisfactory, relative or absolute health being restored by the operation.

Dr. WALLACE ANDERSON said that all the patients in his series, operated upon in each instance by Mr. Carslaw, were drawn from the east end of the city, where the conditions, domestic, environmental, and social, must be distinctly less favourable to complete and speedy convalescence from any abdominal operation than elsewhere. He considered that seven of his eleven cases were complete "cures," inasmuch as the patients were now free from symptoms, and quite able to carry on their previous duties. Of the remaining four, two patients admitted improvement, being able to work, but not being so well as they ought, and hoped, to be. One of the seven "cures" was a patient who, prior to operation, had a course of medical treatment lasting six weeks, in one of the infirmaries, for "duodenal ulcer," with no real benefit. The others had had variable amounts of medical treatment at home, without apparent improvement. The remaining two cases of his series had both had operations prior to that of colopexy. One of them had had gastro-jejunostomy performed some years before, with no remission of symptoms. The result of his colopexy was not yet certain, as he was still in hospital, recovering from a secondary operation, undertaken for the purpose of replacing the original gastro-jejunostomy. Dr. Anderson had therefore classified him in the meantime as a "failure," although he hoped ultimately to be able to remove him from that category. The last case he considered a complete failure. The patient was a typical "abdominal woman," who, prior to coming under his care, had had two abdominal operations, presumably gynaecological in nature, with no benefit. As she was no better after colopexy, Dr. Anderson had her admitted at a later date to the Eastern District Hospital, where she improved for a time on treatment for "migraine." She was subsequently sent to the Western

Infirmary, in which institution she underwent a further abdominal operation. Her present condition was unknown to him. It had been argued that, as the appendix was removed as a routine in the operation of colopexy, it was therefore impossible to be certain that any subsequent improvement was due solely to the fixation of the ascending colon. Against this argument Dr. Anderson was able to state that in all his cases the appendix was to all appearance normal, and that in no fewer than twenty-nine of Mr. Carslaw's cases appendicectomy had been performed prior to the colopexy operation. Though not a panacea, the operation of colopexy had a definite place in abdominal surgery, and deserved the careful consideration of surgeons and general practitioners.

Dr. W. M. KNOX stated that during the previous five years he had had a series of eighteen patients operated on for this condition. Ten of these cases were of long standing, and there were symptoms of chronic gastro-intestinal intoxication, such as mucous colitis, anaemia, anorexia, constipation, and nervous symptoms. All these patients had undergone prolonged medical treatment, such as dieting, rest for varying periods, and intestinal antiseptics, with only temporary relief. All welcomed operative treatment as a possible escape from their prolonged suffering, and with only two exceptions the results had been satisfactory. In three other cases the appendix had been previously removed without any amelioration of the condition, but after colopexy recovery was complete. The remaining five cases were of the gastric type of comparatively short duration and were completely cured. Dr. Knox concluded that even in long-standing conditions operation proved beneficial; that unsatisfactory results followed the removal of the appendix without colopexy; and that an early operation was necessary in order to obtain the best result.

Dr. DOUGLAS RUSSELL asked why there were 10 per cent. of these cases associated with duodenal ulcer if a mobile caecum was such a very important factor in the causation of duodenal ulcer. There seemed to be a discrepancy somewhere. Many of the cases were said to be associated with defective innervation, but his opinion was that it was the mentality of the patient that was at fault. Dr. Russell exhibited an æ-ray film of a patient with a mobile caecum treated by colopexy four years previously. The film showed the caecum lying in the deepest part of the pelvis and the stomach atonic and greatly ptosed. Yet the patient was undoubtedly cured by operation although the colopexy had been a complete failure. The difficulty was to estimate, in the "mental" type of patient, whether they were likely to benefit by operation. Such patients could be diagnosed almost at sight, by their flabby aspect and stance, due to a wide sigmoidal curve of their vertebral column.

Mr. JAMES TAYLOR said it had been suggested that the various bands occurring in connexion with the bowel were congenital in nature and were not acquired as the result of the traction downward of the loaded intestine. It was perfectly true that there were congenital bands, because the bowel must be supported in some way even in the child. But the bands that Lane had so aptly described as the "crystallization of lines of force" developed within the congenital folds. The one at the terminal ileum was most often seen, not because it was actually the commonest, but because it occurred in the region of the abdomen that was most frequently explored by the surgeon. It would be seen that this band was a dense white fibrous fascia occurring between the layers of the mesentery, and the under surface of this mesentery had to be cut through to allow this band to be divided. It was a structure which had formed in a congenital fold. The benefit that resulted from colopexy might be due to the straightening out of the terminal ileum. Viewing this part of the bowel as forming a very acute arch with the caecum and last inch of the ileum on one side and the next portion of the ileum on the other, Lane obtained his result by dividing the band supporting the summit of the arch, while Waugh, by fixing the caecum and ascending colon at a higher level than they were before, brought the outer limb of the arch into line with the inner limb. As Lane also straightened out the kinked pelvic colon, colopexy was really a modification of part of Lane's operation.

THE DICK TEST.

AT a joint meeting of the Manchester Medical Society and the Pathological Society of Manchester on January 12th, Dr. A. A. MUMFORD in the chair, Dr. D. SAGE SUTHERLAND opened a discussion on the clinical value of the Dick test and the preparation and use of scarlet fever toxin and antitoxin.

Dr. Sutherland stated that in 30 cases of definite scarlet fever during the first three days of the rash distinguishable blanching was obtained with dilutions of immune serum up to 1 in 5,000 in from twelve to twenty-four hours. In two doubtful cases of scarlet fever, where no blanching was obtained, the subsequent clinical symptoms confirmed the diagnosis as being other than scarlet fever, and in three cases where the rash was definitely due to another cause no blanching was observed. Among the members of the nursing staff at Monsall Hospital 15.3 per cent. were found by the Dick test to be susceptible to scarlet fever, and were immunized before being detailed for duty in scarlet fever wards: 23 per cent. were found susceptible to diphtheria, and were protected by immunization. During the last six months no cases of scarlet fever or diphtheria had occurred among nurses thus protected. Of 354 diphtheria patients who were Dick-tested on admission to hospital, 55.9 per cent. were found susceptible to scarlet fever. The proportion of susceptibles was found highest—83.3 per cent.—at the age period of 1 to 2 years. Of 589 scarlet fever patients who were Schick-tested on admission for susceptibility to diphtheria, 56.5 per cent. were found susceptible. The proportion of susceptibles was highest at 5 years of age, reaching 75 per cent. The standard of immunity of diphtheria patients to scarlet fever was lower than that of patients suffering from scarlet fever to diphtheria up to the age of 5 years. After 7 years the reverse applied, and in both diseases the standard of immunity was much lower than among an average healthy community. A table of Dick tests with a standard dilution of 1 in 1,000, classified according to day of disease, on 566 definite cases of scarlet fever on admission to hospital, showed, in a survey of 463 patients during the first five days of illness, that 83.6 per cent. were Dick-positive. Of those giving negative reactions during this period, 36 had intensely marked rashes, which may have masked the reaction. On the second day of rash 86 per cent. were found to be positive reactors, and, by including possible masked reactions where the rash was intensely marked, this percentage of positive reactors could be raised to 95.5. It was suggested that the remaining 4.5 per cent. of negative reactors might be accounted for by rapid development of immunity during the incubation and invasive period of the disease. These figures closely approximate to those of Zingher of New York. Dick tests on 150 early cases of scarlet fever, at successive short intervals, demonstrated the establishment of immunity in 90 per cent. of cases at from nine to fifteen days, the remaining 10 per cent. becoming negative in from two to three weeks. In a scrutiny of nearly 800 cases of scarlet fever during the last five months, in about 20 cases where the diagnosis of scarlet fever was undoubted, and where susceptibility, as indicated by the Dick test, had persisted beyond four weeks, a reinfection or relapse had in nearly every case occurred, at periods varying from four to six weeks, followed in a few days by a Dick-negative reaction. It was noticed that these cases were marked in the primary attack by a very slight degree, or absence, of pyrexia, the other symptoms, including subsequent desquamation, being characteristic. It was recommended that such cases be actively immunized to establish immunity by the twenty-first day. Three hundred skin doses of toxin were sufficient to change a positive to a negative reaction, and this dose was unattended by any constitutional disturbance. A Dick test on all cases at the onset of illness and on the twenty-first day was recommended. The use of the test was summarized as follows. A very strongly positive reaction early in the disease and again late in convalescence was against the diagnosis of scarlet fever. A definite negative reaction during the first two days of rash should warn the practitioner that he was not dealing with a case of scarlet fever. The Dick test should be applied to the diagnosis of sore throat and pyrexia

associated with definite cases of scarlet fever in the same family. The test was useful in determining the establishment of active immunization and in estimating the potency of antitoxic serum. In the diagnosis of scarlet fever the test should be interpreted in relation to the susceptibility of healthy individuals at the age period of the patient. The test was specially useful on the occurrence of scarlet fever in a diphtheria ward. The Dick test made on admission would indicate without delay the susceptible patients, and protection could be immediately rendered by a prophylactic dose of immune serum. During the last year, on two occasions, in a diphtheria ward of fifty beds, an outbreak of scarlet fever had been followed by no secondary cases when such a course was adopted. It was recommended that in surgical wards where exposure to scarlet fever was suspected, patients who had not previously suffered from scarlet fever should be Dick-tested before operation and prophylactic serum administered where the reaction was positive. The value of immunization in case of extensive burns was indicated, even in the absence of exposure to the infection of scarlet fever.

Dr. R. A. O'BRIEN called attention to the importance of the protection of nursing staffs in fever hospitals and the 10 per cent. incidence of scarlet fever in some hospitals. At Monsall both diphtheria and scarlet fever were in process of disappearing since Schick and Dick testing and immunization had been introduced. Among the nurses, apparently 40 out of 45 with a previous history of scarlet fever gave a negative response to the Dick test, and 18 out of 19 nurses with a previous history of diphtheria gave a negative response to the Schick test. The Dick test during the first three days of the attack of scarlet fever was positive in the Monsall series in 217 out of 251. It was noted, however, that 28 of the negative reactors had very vivid rashes. Presumably in such cases the capillaries were dilated to their fullest extent by the circulating toxin, and no local introduction of the Dick test amount of toxin could increase this dilatation. In other words, these patients presented a "universal Dick-positive response." If these 28 cases were deducted, the test was positive in 217 of 223 patients, or 97 per cent. The figures for the test applied up to the fifth day of the disease were 388 positive and 27 negative ("vivid rashes" being eliminated), or 93 per cent., whereas from the sixth day onwards the percentage dropped to about 60. All such collections of figures showed that measurable immunity developed rapidly in the average patient at or about the fifth day; this agreed with clinical experience. The Schultz-Charlton test was positive in 35 successive cases admitted and tested during the first three days of the rash. The test was obviously of considerable use in practice, and it was now in routine use in several hospitals in the examination of all "doubtful" cases of scarlet fever. Blanching in this series had been obtained with serum diluted to 1 in 4,000. Evidently a reasonably good serum for clinical use would in this dilution produce blanching in the great majority of patients tested during the first two days of the rash. The clinician had thus in his hands a method of rough measurement of the clinical value of any serum he proposed to use for treatment. The comparison of the Washington Dick toxin with that in use in many places in this country suggested that in corresponding dilutions the two toxins were of nearly equal potency. The comparison would be resumed later when a further sample of the American toxin was available. Apparently, among some 600 to 800 patients convalescent from scarlet fever at Monsall, about 20 gave a positive response to the Dick test at or after the third week of convalescence. The Monsall plan of giving a small injection of toxin to such patients found to be Dick-positive on the twenty-first day, and the resultant negative Dick reaction a week later was of great interest to the immunologist, and probably of equal interest to the administrator. It might prove to be a better treatment than giving passive immunity to such patients with antitoxin. "Second attacks" of scarlet fever during the stay in hospital caused a considerable amount of trouble to all concerned. Dr. O'Brien showed figures illustrating the results got by the Parish-Okell rabbit test, which promised to be of considerable use in the titration of antitoxin and, possibly, in the identification of pathological haemolytic streptococci.

HELMINTHS AND DISEASE.

AT a meeting of the Section of Comparative Medicine of the Royal Society of Medicine, held on January 26th, the President of the Section, Sir D'ARCY POWER, in the chair, Dr. T. W. M. CAMERON contributed a paper on the helminth parasites of animals and human disease.

Dr. Cameron said that parasitology, better perhaps than any other branch of medicine, served to draw attention to the close interrelationship existing between curative, preventive, and comparative medicine. Apart from the case of *Hymenolepis nana*, all cases in which man acted as an intermediate host to animal parasites must be considered as accidental, as the parasite was side-tracked and unable to continue its life cycle. Some forms did, however, often thus occur accidentally in man, and these included some of the most dangerous of human parasites. The most serious of these was the hydatid cyst, a parasite only too common in Britain. Dr. Cameron had recently drawn attention to the modern conception of the life-history of this form,[1] and he only desired to consider its epidemiology on this occasion. The adult form lived in carnivorous animals, especially the dog; but there was evidence to suggest that the fox was a common carrier in Britain at least. Practically any animal might harbour the cystic stage, but the sheep was most commonly affected, and so the disease was commonest in pastoral countries, such as Iceland, Australia, South America, and North Africa. There infection reached very high figures, and in some as many as 100 per cent. of the animals were infected. In sheep and cattle, however, unlike human beings, infection was generally in the lungs, not the liver. The disease in man was usually studied in adults between the ages of 20 and 40, but it was in childhood that the great majority of the infections took place. Owing to its slow growth, the cyst was not diagnosed until adult life, except when for mechanical reasons, such as infection of the eye or brain, diagnosis was early. It had generally been considered that the commonest means of infection of man was through the drinking water; but the recent work of Ross in Australia suggested that this was not so and that personal contact with dogs was more important. In Iceland, infection was attributable to the peculiar habit of herding ewes in limited areas near the house, where the fleeces became soiled with the droppings of the dogs, and so the eggs were transferred to the hands of the women and children; the men meanwhile had taken the rest of the flocks to the hills.

Two species of *Taenia* occurred in man, the commoner being *Taenia saginata*, in spite of the prevailing belief that *T. solium* was more frequently found. This last species did occur, although it was very rare, especially in Britain. The larval stage of both of these forms could live in man; and this was particularly the case with *C. cellulosae*, which often chose such unusual habitats as the eye and brain. A similar cysticercus was occasionally seen in sheep in Britain, but this was the larval stage of a dog worm which could not be transmitted to man. *Dibothriocephalus latus*, although common in Europe, was probably now absent from Britain. Its second larval stage occurred in fish, and in Switzerland cats probably acted as reservoir hosts. The larval stage of a related form was often found in man in the Far East under the name of *Sparganum mansoni*. There was some doubt about the unity of this species, the adults of which were found in dogs and cats. Another important species was *Trichinella spiralis*. How long the disease called trichinosis had been recognized was unknown, but it was probably the chief cause of the Mosaic injunction against the use of pork—an injunction which had been drawn from even older Semitic civilizations. It was first recognized in London, in 1828, and about fifty years later was responsible for international complications between Germany and the United States, and was the direct cause of the present efficient American system of meat inspection. The importance of the parasite was slight where pork was overcooked before use; and epidemics were practically confined to persons who ate raw or smoked sausages. Dr. Cameron here drew attention to the frequent diagnosis

[1] BRITISH MEDICAL JOURNAL, November 20th, 1926, p. 940.

of "typhoid" or "ptomaine" poisoning in acute cases and of "rheumatism" in chronic cases of the disease. Symptoms in the pig were generally absent, and the flesh to the naked eye was unchanged. Rodents were often infected, but in them the symptoms were often very severe, and this suggested that these animals might be accidental hosts. The distribution of the disease in Britain was unknown, although it did occur. It must be remembered that symptoms were directly proportional to the numbers of worms swallowed, and slight infections probably showed no symptoms at all, were unlikely to come to the attention of the physician, and were still less likely to be diagnosed. One of the commonest of the remaining parasites of dogs liable to be transmitted to children was *Dipylidium caninum*, a tapeworm, the intermediate stage of which occurred in fleas. The diagnosis of this parasite in children often subjected the physician's tact to a considerable strain and caused him unnecessary anxiety owing to confusion with *Echinococcus*. Children were also occasionally infected with the several species of ascarid worms of dogs and cats. In certain cases parasites found in animals were morphologically indistinguishable from those in man, but cross-infection experiments proved negative. In these cases it was possible that biological strains existed. This was the case in *Ascaris*, *Necator*, and possibly *Trichocephalus* of the pig and man, and *Hymenolepis nana* in mice and man. Until these strains had been more thoroughly investigated it was better to consider the animals as potential carriers to man. A list of parasites of man and animals showed that with few exceptions all the human forms were found in animals. The exceptions were the pinworm, related forms of which occurred in monkeys, *Filaria bancrofti*, the Egyptian *Schistosomes*, and the human *Taenias*. In all of these cases, however, closely related species occurred in domestic animals.

In conclusion, Dr. Cameron drew attention to the probable evolution of human parasites. Many of these were apparently of herbivorous origin in early evolutionary days, but a few were apparently from carnivorous animals. He referred to Darling's notion that the geographical distribution of the human hookworms suggested that two strains of anthropoids had originally existed—one from holarctic regions and one from Ethiopian regions. The first was *Ancylostoma duodenale*, which occurred in the Caucasian and Mongolian peoples; and the second was *Necator americanus* (which, in spite of its name, came from Africa), and it was found in negroid people. The first was of carnivorous origin, the second of herbivorous origin. He considered that the parasitological evidence suggested that man had in the course of his evolution had occasion to change his diet. The parasites which, in modern times, man might acquire from animals were only very seldom acquired from herbivorous animals. The usual hosts of these forms were dogs, cats, and pigs. He thought that the strong resemblance between the parasites of man and the pig were due to diet and the facilities that the animal had for acquiring parasites passed in faeces.

Sir D'ARCY POWER noted that he had seen two human cases of trichinosis, both of which had originally been diagnosed as acute rheumatism. He suggested that fish would be a probable source of infection of our pre-human ancestors, as this was a large part of their diet.

Dr. NICOLL pointed out the comparatively small number of parasites which monkeys had in common with man, and remarked on the surprising lack of knowledge about the parasites of man; this was a matter that should be much more studied.

Professor R. T. LEIPER drew attention to the fact that a number of parasites of man in Central Africa were common to man and monkeys. He thought that man's parasites had probably been influenced by three factors: change of food, association with domestic animals, and simian forms. It was peculiar that none of the parasites of the horse ever occurred in man, considering the close relations which used to exist between man and this animal.

LIGHT TREATMENT IN SURGICAL TUBERCULOSIS.

AT a meeting of the Section of Electro-Therapeutics of the Royal Society of Medicine on January 21st, Sir HENRY GAUVAIN gave an address on light treatment in surgical tuberculosis, based chiefly on his experience at Alton and Hayling Island.

Sir Henry Gauvain said that the sun was not to be regarded as a specific treatment or a cure for all forms of surgical tuberculosis, but rather as an aid to, and an accelerator of, cure in suitable cases. Residence under conditions generally regarded as ideal for the practice of sun treatment neither protected individuals from infection nor necessarily aided in treatment, and the disease, even in these circumstances, might proceed to a fatal termination. Tuberculosis was endemic in Switzerland, and the sun treatment of patients in the high Alps by no means necessarily resulted in cure or even amelioration. No adequate explanation of the *modus operandi* of light in the amelioration of tuberculous disease had as yet been advanced. Certain specific effects followed light treatment, but these did not offer a sufficient explanation of the benefits which might follow insolation or of the failure of light treatment in many cases. He advocated a wider consideration of the action of sunlight. Given adequate light of the right therapeutic character and intensity the only unchanging phenomenon in sun treatment was the reception of stimuli which were constantly changing. The importance of these changing stimuli was emphasized, and in this way an explanation of the value of insolation in districts not notably sunny was afforded. Sun treatment for its general effects in surgical tuberculosis was more suitably administered in the constantly changing conditions found in temperate climates than in the comparatively more stable conditions found in many tropical regions, where the intensity of the light might be much greater. The benefits of insolation, after a certain intensity of light was obtainable, were derived, not from the action of light alone, but from the shock of varying stimuli eliciting favourable responses. As an example of one of these favourable responses was instanced the effect of cold air on the nude body in increasing basal metabolism. The varying responses of individuals to insolation were discussed. They were noted clinically, and the optimum dosage of sunlight could not be determined accurately by physical measurements of light intensity or the observation of isolated physiological effects. The best guide was afforded by clinical observation and experience. Pigmentation of the skin, inasmuch as it was protective and allowed more prolonged exposure to light and cold air, was an advantage. The patient's individual power of response should be carefully studied, as on that depended much of the success of insolation. Practical methods of improving heliotherapeutic treatment in England were suggested and the value of combining with it suitable artificial light treatment was discussed. Artificial light treatment for surgical tuberculosis owed much of its lack of success to the non-recognition of fundamental essentials. Constant intensity of light with regular exposures under the unvarying conditions found in a light department could not be expected to produce optimum benefits. A certain minimum of light, varying with the individual, might be considered as essential for the conduct of light treatment, but after that greater importance was attached to varying intensities and times of exposures, in this way simulating more nearly light therapy under natural conditions. Local light treatment of superficial lesions should be governed by entirely different rules of application. As an example, in lupus vulgaris light was of value by its direct bactericidal action, its thermal effect, and the favourable inflammatory response which suitable exposure elicited. The value of general light treatment in any particular district depended only in part on the intensity and nature of the sunlight available. For some individuals very intense light was the reverse of beneficial, particularly in the case of cachectic patients with little power of response. What was of much greater value was the application of varying light and other stimuli, graded and varied according to individual needs. Patients able to

respond well would do well under intense stimulation, whereas with weaker cachectic and elderly patients great caution should be exercised and only slight stimulation was at first appropriate.

MORTALITY FROM MAMMARY AND UTERINE CANCER.

AT a meeting of the Section of Epidemiology and State Medicine (Royal Society of Medicine), held on January 28th, with Dr. S. MONCKTON COPEMAN in the chair, a paper was read by Dr. MAJOR GREENWOOD and Dr. JANET LANE-CLAYPON on "The possibility of effecting a reduction in the present mortality rate from cancer of the breast and of the uterus."

The paper, which was read by Dr. Greenwood, presented a great amount of admirably arranged statistical matter, obtained from various sources, national and local, concerning on the one hand the deaths from cancer at these sites, and on the other the number of hospital applicants and operations. The authors combated one statement, not *infrequently made, that a considerable proportion of* inoperable cases of cancer must be accepted as permanent. This was based on the assumption that many patients were unaware of their condition until the condition was too far advanced for effective surgical treatment. It was shown on the basis of a number of cases that on the average a period which could be measured by months elapsed between the recognition of an abnormality by the patient and her submission to medical examination. In cancer of the breast this mean alleged duration—alleged, that is, by the patient—was eight to twelve months. A lump in the breast was nearly always discovered by the patient herself; occasionally, when there was complaint of pain, the lump was discovered only by the examining surgeon. It was remarkable for how long a time some patients would endure their symptoms before calling in medical aid, but the point was established that there was avoidable delay both in cancer of the breast and of the uterus. The authors showed a table giving the death rates from cancer at these sites for different ages, and remarked upon the steady tendency for the mortality to increase with advancing age. It was a disturbing fact that this increase in England and Wales contrasted with what was found in other countries. In Holland the rate of mortality from cancer of the breast underwent three phases; it rose rapidly from 35 to 55, then there was a slight slackening until 70, after which there was again a rapid rise. An elaborate investigation carried out in Holland furnished no satisfactory proof that surgical intervention was in fact more frequent or more timely than in England and Wales. The deaths in this country from breast cancer in relation to age periods showed that about 47 per cent. occurred after the age of 60, and 24 per cent. after the age of 70. It was possible to compare these proportions with figures relating to the ages at which treatment was sought by applicants at hospitals in six large county boroughs. Only 17.6 per cent. of the applicants were over 60, and less than 3 per cent. were over 70. In London it appeared that not more than 50 per cent., perhaps not more than 30 per cent., of women dying from cancer of the breast had been operated upon, and similar statistics from certain large towns were only slightly better. Evidently a great number of women died without seeking or obtaining radical treatment; a good proportion of these, of course, would be older women. Some interesting figures were obtained in Leeds illustrating the advantage of early operation. In cases in which early operation had been done for cancer of the breast (eighty-seven cases), 56.9 per cent. were surviving after ten years. Of all cases operated on at whatever stage (357), 25.9 per cent. were surviving after ten years; but in untreated patients the number surviving after six years was negligible. The authors then went on to discuss various necessary qualifications and assumptions, but broadly their opinion was that, without any fresh accession of scientific knowledge, and merely as a result of education and administration whereby cases might be brought forward earlier and facilities for operation made more available, the deaths from cancer of the breast might be reduced to half the present number. No revolutionary improvement in the art of surgery need be postulated, but annually many thousands of lives might be saved. It was a question of the respective parts played by administrative action, whereby more hospital provision might be made for operable cases, education of the public, and education of the practitioner. Surgeons as a whole had been unduly despondent as to the possibilities of their art under these conditions.

Sir JAMES BERRY described the paper as the best contribution to the subject of cancer of the breast that he had heard for many years. It showed the striking way in which the mortality incidence of cancer varied directly with age, and it bore out what he had said at the annual dinner of the society, that, without decrying laboratory and pathological research, there was another kind of research—namely, clinical research on case records available in hospital reports, Government publications, and other sources of information, which might be studied with advantage.

Sir LENTHAL CHEATLE said that the mortality of breast carcinoma could be reduced if cases were obtained early *enough. Operations took place too late.* He considered that diffuse nodularity of the breast, except in very thin breasts, was not of great importance, for with increasing age every breast might be described as nodular, but localized nodularity was highly important, and a sign often neglected.

Mr. SAMPSON HANDLEY said that in some respects the authors had been unduly pessimistic. They appeared to think that the saving of life by operation was not likely over the age of 70. He did not agree with that. Old people nowadays often stood severe operations very well indeed. He agreed that breast cancer could be detected much earlier if women were more observant, but, of course, there were cases where no lump at all formed, and yet the disease disseminated into the gland. On the previous day he saw a patient who had discovered a lump in her breast, which proved to be carcinoma, as a consequence of the warning given in Sir Berkeley Moynihan's Hastings Lecture three nights before; the lecture had probably saved her life. His experience was that pregnancy kept breast cancer in check, but that it "romped" as soon as the child was born and lactation began. The facts which the public required to know about cancer were few and simple: that early cancer was curable, that the important thing was to seek early advice, and that early cancer was almost always painless.

Dr. STANLEY WYARD (Cancer Hospital) thought that it begged the question to speak of getting cases in the early stage. In the majority of cases, by the time the disease was diagnosable it was no longer local. He was sceptical about the desire of the mass of the public for education, or its capacity for accepting it.

Dr. WILLIAM CRAMER asked whether it was proposed to operate on every suspicious case; this might mean operating on five patients for one who was found to have early carcinoma or even a condition potentially malignant.

Dr. F. J. MCCANN suggested that the only way to get patients earlier for observation was to propose a medical overhaul once a year. Every woman over 35 should pay an annual visit to a doctor for examination in view of possible breast or uterine cancer. All irregular bleeding in women demanded a careful local examination. All excessive bleeding at the menopause should give rise to a suspicion of cancer, and all bleeding after the menopause should be assumed to be due to cancer until the contrary was proved. He regarded the thickening of the cervix seen in multiparous women over 40 years of age as a pre-cancerous condition.

Dr. T. H. C. STEVENSON referred to the great rarity on death certificates of a differentiation between cancer of the uterus and of the cervix. This differentiation during the last sixteen years had been made in so few cases that it was not worth mentioning. The uterus was the one important site of the body as to which the official returns showed an actual decline in mortality from cancer at the present time. Was this due to improved diagnosis?

Dr. JANET LANE-CLAYPON, in replying, said that data as to the growth of cancer of the breast during pregnancy were very slight. More cases properly reported under this

head were wanted. She had particulars of several cases in which she really did not know whether the primary site was the breast or the uterus. They had been operated on for the one and had died of the other. She thought cancer of the breast secondary to that of the uterus must be very rare, whereas there were more cases of primary breast cancer and secondary uterine. She was sorry that Dr. Wyard was so very pessimistic. She hoped as time went on they would be able to disprove some of his pessimism. She admitted, with Dr. Cramer, that early diagnosis was somewhat difficult, but the greater difficulty was to get hold of the patients sufficiently early.

CARCINOMA OF THE STOMACH.

AT a meeting of the Forfarshire Medical Association at University College, Dundee, on December 19th, 1926, the President, Dr. R. C. BUIST, in the chair, Dr. CHARLES KERR opened a discussion on carcinoma of the stomach.

Dr. Kerr, dealing with the medical aspect, said that the past thirty years had shown little advance in the diagnosis apart from the chemical and radiological examinations. In cases of acute type pain was usually the prominent feature; the subacute onset was associated with apparently causeless indigestion. In the chronic type there was a history of prolonged dyspepsia suggesting gastric ulcer, while palpable tumour and pain were usually late in appearing. Anorexia, increasing weakness, and fatigue were early symptoms, and in a patient of cancer age should cause hesitation in giving as a diagnosis simple gastric ulcer. In cancer of the stomach the first duty was early diagnosis, and a careful history was the first essential. In indigestion, if treatment was not followed by rapid improvement, it was no longer safe to assume that a simple ulcer was present; blood examinations, test-meals, and x-ray examination must be added.

Mr. JOHN ANDERSON, from the surgical standpoint, referred to the common occurrence of cancer of the stomach. In Dundee, in 1924, there were 83 deaths from cancer of the stomach and oesophagus (40 males, 43 females), 30 per cent. of all the deaths were due to cancer, and there was an incidence rate of 1 in 2,000 of the population. He was satisfied that there was definitely an acute type of cancer of the stomach, distinguished usually by haemorrhage followed by anorexia. In the chronic type indigestion was associated with offensive gastric flatus. Several recent patients had voluntarily stated that the gas tasted like petrol. Anaemia was an early symptom, and blood could generally be found in the faeces if carefully looked for. Symptoms in cancer of the pyloric half of the stomach were of two types. If the tumour was at the pylorus they were those of obstruction; if in the pre-pyloric region those of gastric ulcer. Dyspepsia in a man over 40 indicated a radiological examination, and an exploratory operation if there was suspicion of organic defect. Mr. Anderson then discussed the operative treatment with illustrative cases, and added that no case should be pronounced inoperable without an exploratory operation.

Dr. GEORGE MILLN discussed the diagnosis from the point of view of radiology, and emphasized the need for repeated examinations, and for co-operation between the radiologist and the clinician.

Professor PATRICK said that in some cases pyrexia and leucocytosis were factors in the diagnosis. Dr. CARRUTHERS referred to the presence of lactic acid and enlargement of the supraclavicular glands as diagnostic points. Dr. FOGGIE discussed the diagnosis from anaemia. Enlargement of the supraclavicular glands he regarded as indicating an advanced stage. Mr. R. C. ALEXANDER stressed the need for exploratory operations, even in some cases in the absence of x-ray confirmation. The CHAIRMAN suggested as a summary that it was wrong to wait for pain, tumour, or emaciation, but in the case of a patient over 40 with indigestion cancer must not be excluded unless some other condition was definitely present.

AT a meeting of the Buxton Research Society held at the Devonshire Hospital, Buxton, on January 19th, with the President, Dr. C. W. BUCKLEY, in the chair, Professor W. TOPLEY of Manchester University gave an outline of the conclusions arrived at from a survey of the bacteriology of rheumatic disease. He laid stress on the fact that infection with streptococcus must be regarded as a necessary and important factor in the etiology of all types of rheumatism. He summarized the present problems, both from the point of view of the pathologist and the clinician; and suggested lines of investigation where co-operation between them might well lead to important discovery. A discussion followed, in which most of the members present took part, on the action and scope of vaccines in the treatment of rheumatic disease.

Reviews.

CANCER: A FRENCH VIEW.

NOTWITHSTANDING the great advances in our knowledge of cancer which have been made in recent years, it has still to be confessed that we are ignorant of the cause of the disease. That is to say, if we take the two extremes of a series of phenomena, for instance, the application of x rays on the one hand and the appearance of cancer on the other, we are still unable to fill up the interval with a complete series of comprehensible steps connecting the one phenomenon with the other. In these circumstances it is desirable, in investigating the subject, that as far as possible all observed facts bearing on the question should be borne constantly in mind; and in this connexion a volume such as that of MENETRIER on cancer[1] cannot fail to be of service. Observations and researches have been so numerous that in default of an ability to take a bird's-eye view of the whole subject there is some danger of adopting a narrow and one-sided opinion.

Menetrier gives an excellent and very full summary, written for the most part on historical lines, clearly indicating the directions taken by research. There are eight sections, dealing respectively with the cancerous process, the chemistry, the biology and the experimental production of cancer, the stages of the cancerous process and its effects on the organism, its clinical course, its etiology, and pathogeny.

It is nearly twenty years since the first edition of the work was published, and it is interesting to note how far ideas have been modified during the intervening period. Menetrier claims that the views on the pathogeny of cancer which were expressed in the former edition have been corroborated by subsequent researches. He then held, and still holds, that cancer is a pathological process which is secondary to the action of multiple and non-specific irritative processes. Cancer has, he says, been produced experimentally by various agents which are, for the most part, non-specific—namely, by physical agents such as x rays, by chemical agents such as tar, and by parasitic irritants, as in the case of spiroptera. He does not exclude parasites as a cause of cancer, but he regards their action as non-specific and analogous to chemical and physical irritants. As to the *modus operandi* of these various irritants, Menetrier considers that, acting as they mostly do over prolonged periods, they cause the development, by a kind of pathological cellular selection, of a new race of cells endowed with the autonomous and agressive properties characteristic of the cancerous process. The prolonged irritation is held to bring about changes in the tissues which constitute an alteration in the environment of the cells and, by a process of adaptation in the more resistant cells, leads to the production of a race of cells possessing cancerous properties.

In view of recent observations a special interest attaches to his opinion regarding the Rous sarcoma. This is now generally regarded as a genuine neoplasm, but Menetrier appears to accept this view in a somewhat modified form. He quotes an observation of Peyron to the effect that although the tumour may be definitely regarded as a neoplasm, its metastases, and especially those situated in the viscera, appear to be due to infection by the virus in the circulation, rather than to the transport of cells from the primary growth. The tumour, therefore, according to

[1] *Nouveau Traité de Médecine et de Thérapeutique.* XIII. *Cancer: Généralités* Par P. Menetrier. Deuxième édition. Paris: J. B. Baillière et Fils. 1926. (Roy. 8vo, pp 432; illustrated. 48 fr.)

Monetrier, exhibits the characters of a special infective disease rather than the typical cancerous process. It has a close analogy with neoplasms as regards its histology, but in its mode of dissemination it exhibits the mechanism of general infections rather than that of autonomous proliferations.

CLINICAL ASPECTS OF VENEREAL DISEASES.

Modern Clinical Syphilology,[2] by Dr. JOHN H. STOKES, professor of dermatology and syphilology, Philadelphia, is the result of work begun five years ago under the stimulus afforded by the Conference on Venereal Disease Control of the United States Public Health Service held at Washington in 1920. In his preface the author describes the book as a "monographic adventure in co-operative syphilology." It is monographic in that the writing is from the pen of one observer; it is co-operative in so far that it is the result, not only of personal observations of the author, but of those of fellow workers at the Mayo Clinic. The material of the book is, however, to a very large extent original, and there is, indeed, a cohesion about it that would have been lost had the author merely acted as an editor. Another feature of the book is that it is written particularly from the clinical point of view. Case histories are given in support of statements in the text. The result has been an increase in vividness and a gain in interest. The various paragraphs are given appropriate headings, and to each is appended a summary of conclusions. In this way the value of the book as a work of reference is enhanced. Indeed, it would be possible for the student to absorb the essence of Dr. Stokes's writing by referring only to the excellent tables, digests, and summaries scattered throughout the book. Naturally when originality is the keynote of a work there are statements which are open to criticism, and in order to keep within the limits of a single volume Dr. Stokes has been compelled to compress, so that he appears to be a trifle dogmatic in some of his statements, but on the whole the method of presentation chosen is the best that could have been adopted. The much-debated point whether the use of salvarsan preparations predisposes to the development of neuro-syphilis is discussed. The question was raised in 1911 by Finger, who reported 9 per cent. of neuro-recurrences in his first 500 cases treated by salvarsan, as contrasting with 0.25 per cent. in 2,000 cases treated with mercury and iodide. Stokes, however, from a survey of cases treated by himself and others, is of the opinion that there has been a decline in the incidence of neuro-syphilis since the introduction of salvarsan. In chapters on the hereditary disease the difficult question of marriage is discussed, as are the requirements of different authorities before permission is granted, the prevention of infection, the advisability of letting the partner know the condition of affairs, and the legal status of marriage in relation to syphilis. The book is complete and satisfactory, and should be of great value to all practitioners who are called upon to treat or to give advice on this important subject.

Colonel HARRISON'S book *The Diagnosis and Treatment of Venereal Diseases in General Practice*[3] has established itself as a standard work. The fact that it has gone through three editions since its publication in 1918, and that a revised second impression of the third edition has now been issued, is a testimony to its popularity. The new impression is intended to bring the work up to date pending the publication of a fourth edition. Although the treatment of gonorrhœa has progressed little, if at all, during the last few years, advances continue to be made in our knowledge of the treatment of syphilis. New serum tests, such as those of Sachs-Georgi, Dreyer and Ward, and fresh remedies like bismuth and sodium thiosulphate, have been introduced, and the malarial treatment of general paresis has been added to our therapeutic resources. These subjects, with others, are discussed in an appendix, and in spite of our failure to advance in the treatment of gonorrhœa some fresh paragraphs on this disease have been added. In discussing the future treatment of this intractable complaint, Colonel Harrison, like the majority of modern workers on the subject, considers that our best hopes lie in attempts to eradicate the gonococcus by remedies acting through the blood stream. Some of the various drugs that have been used as intravenous injections are described in the appendix, but it would appear from the author's remarks that the employment of these injections has met with but indifferent success in his own practice.

INTESTINAL TUBERCULOSIS.

DR. LAWRASON BROWN and Mr. H. L. SAMPSON, in *Intestinal Tuberculosis*,[4] propound the thesis that many digestive disturbances occurring in the course of pulmonary tuberculosis are due to ulceration of the intestine. By the usual methods employed it is extremely difficult to arrive at a diagnosis of this condition in its early stages; but by careful *x*-ray examination a diagnosis can, they say, be made in nearly every case. The importance of detecting ulceration in its early stages lies in its rapid response to treatment by heliotherapy.

The evidence on which this thesis is based occupies a large part of the book, and is not easy to summarize. Only by a study of the numerous tables and photographs provided can an intelligent appreciation of the conclusions be attained. The chief interest of their work lies in the almost extravagant claims made for roentgenological examination. Briefly, they find that when ulceration of the intestine is present, there is general hypermotility with complete, or nearly complete, emptying of the colon in twenty-four hours. The cæcum, and often the ascending colon, apparently suffer from spasm, which prevents their proper filling; barium is therefore passed on, to collect in the distal portions of the bowel. Even after a barium enema the same emptiness of the cæcum is found. In some cases the cæcal spasm causes an ileal stasis, often with dilatation of the small intestine. As evidence of the value of this method they state that sixty-two patients in whom intestinal ulceration was diagnosed by roentgenological examination were all found either on operation or at autopsy to be suffering from tuberculous colitis. On the other hand, of forty-six patients in whom ulceration could not be detected, only two were shown at operation or necropsy to be so suffering.

The claim that intestinal ulceration, at any rate in the early stages, is benefited by heliotherapy, or ultra-violet ray treatment, depends partly on pathological and partly on clinical studies. Dr. Gardner, pathologist to the Trudeau Foundation, who was responsible for the pathological work, found that in 40.6 per cent. of patients dying with intestinal tuberculosis there was evidence of healing and of epithelial regeneration. This was noticeable especially in those that had received ultra-violet ray treatment. Clinically, it was observed that in patients who were suffering from intestinal ulceration treatment by ultra-violet rays brought about rapid improvement; within three months the condition in 91 per cent. of these cases was ameliorated. In a large proportion complete relief of symptoms was obtained. How far this improvement was due to healing of the ulcers it is impossible to say. The disappearance of symptoms, while very satisfactory in itself, is no proof of a simultaneous resolution of the lesions on which they depend. A systematic use of the roentgen rays in following the progress of these patients would have helped to elucidate this question. Unfortunately this was not done.

Besides putting forward a very interesting thesis, the authors have collected a large amount of valuable information on intestinal tuberculosis. It is a pity that their

style is not more clear; many sentences are ambiguous or frankly unintelligible. Apart from this defect, they are to be congratulated on the production of a book that is alike a credit to their industry and a benefit to the medical profession.

COLLECTED PAPERS OF THE MAYO CLINIC.

THE seventeenth volume of the *Collected Papers of the Mayo Clinic and the Mayo Foundation*[5] contains references to no fewer than 167 papers, some being considerably abstracted and a large number given by title only. There are 161 contributors; many of the papers are the result of combined or team work, and some of the contributors have several papers to their names; thus Dr. William J. Mayo has seven, his brother Dr. Charles H. Mayo five, Dr. J. S. Lundy seven, Dr. V. C. Hunt six, and the late R. D. Carman, the distinguished radiologist, three. As in previous issues, the papers are arranged under the heads of the alimentary tract, urogenital organs, ductless glands, blood and circulatory organs, skin and syphilis, head, trunk and extremities, chest (a new one), brain, spinal cord, and nerves, technique, and miscellaneous. Not unexpectedly, the alimentary canal tops the list with 42 articles, though followed rather closely by the urogenital organs with 37; other double figures are the blood and circulatory organs (19), the head, trunk, and extremities (17), and skin and syphilis (12). Under miscellaneous there are twenty-two articles, and among them the reader is naturally attracted by the title "The twilight zone of medicine," in which Dr. William Mayo remarks that we perhaps stand to-day facing the twilight zone of a new ultra-microscopic world of science, and goes on to illustrate the application of physico-chemistry to disease, as shown by the way in which knowledge of the blood changes in diabetes, alkalosis, and jaundice bears on their successful treatment. Dr. F. C. Mann, director of the division of experimental surgery and pathology of the Mayo Foundation for Medical Education and Research, Graduate School, University of Minnesota, has a hand in nine papers, six of them dealing with the liver and two with peptic ulcers. In a well illustrated paper on cardiospasm, Dr. P. P. Vinson mentions that since 1908 500 cases of this condition (294 males and 206 females) have been observed at the Mayo Clinic. By forcible dilatation 75 per cent. of the patients were cured. Dr. W. A. Plummer writes on the early recognition of thyroid adenoma with hyperthyroidism and of exophthalmic goitre, and lays stress on the diagnostic value of increased appetite, loss of weight, and increased tolerance for cold. This article is appropriately followed by Dr. J. Pemberton's essay on the present-day surgical treatment of thyroid diseases. Investigation of the blood in high blood pressure led Drs. S. F. Adams and G. E. Brown to state that in 60 per cent. of the cases of benign and malignant hypertension with arterio-sclerosis but with adequate renal function the haemoglobin is more than 100 per cent.

This volume is a veritable storehouse of recent research, and therefore an invaluable, if rather expensive, source of reference.

NOTES ON BOOKS.

INTO his small book *The Air We Breathe*[6] Dr. JAMES KERR, formerly school medical officer for London, has managed to compress an enormous amount of information. The condensation is such that we are not sure that the people for whom the book is written will grasp fully its contents, notwithstanding the glossarial notes which the editor of the Modern Health Books, Professor Fraser Harris, scatters through the pages of his contributors. Dr. Kerr summarizes early notions about the air; shows how a hypothesis like the phlogiston theory may form the basis of a huge superstructure of error; describes the process of respiration; and concludes that the process is unaffected by any chemical changes or alterations likely to be met with in ordinary life. He devotes several chapters to ventilation, heating, and the removal of bodily heat, and has something to say on colds and chills. Dr. Kerr is sometimes dogmatic in his statements, as when he says, "tuberculosis is omnipresent in civilization. It attacks every one in the community." He is of opinion also that a six-hour working day, with proper administrative distribution, should suffice to enable any democracy to gain their necessary subsistence. The new hygiene, he thinks, entails a new outlook on the human body, which should no longer be regarded as "vile." The health game needs pushing in primary schools, but instruction in the principles and practice of health is still, he asserts, largely make-believe in the teachers' training colleges.

Dr. BEGGS, the medical officer of health for Middleton, Manchester, has written a little book on *The Hygiene of Infancy*.[7] There is an introduction by Professor Bostock Hill. It is in the form of a catechism—a form that undoubtedly has its value to many minds, and particularly to those who are not habituated to reading and analysing what is read. There are chapters on all matters relating to birth and infancy, from the attendance of the expectant mother at the ante-natal clinic to the evils of flea-bites. The questions are devised with good judgement, and for the most part the answers are short, sharp, and sufficient. There are some deficiencies which might well be remedied. Among the warnings to the expectant mothers there are some on "racial poisons," but there is none that attention is required if there be a vaginal discharge; and there is no reference to the necessity for carefully cleansing the infant's eyes after birth, or for special precautions in the first bath, or for setting a watch on the eyes for the first few days of life. The chapter on the law in relation to children is very good, and might well be brought to the attention of some members of local authorities with advantage.

Dr. J. DENNY SINCLAIR has translated Dr. MARC JACQUEROD'S book on *The Natural Processes of Healing in Pulmonary Tuberculosis*,[8] the French edition of which was reviewed in our issue of January 10th, 1925. For reasons apparently connected with the difficulty of translation, some parts of the original book have been omitted, notably the chapter on classification. What remains is very short, and the volume is occupied largely by reproductions of *x*-ray photographs with their attendant case histories.

Mme PHILIPPE BELLOCQ has written an interesting study on the vascular supply of the skin.[9] She has employed a radiographic method, injecting the arteries with a mixture of red lead or vermilion with oil of turpentine. After the injection has been completed the area of skin which is the immediate object of study is removed, stretched, and radiographed. Stereoscopic radiography is often found useful in order to follow the course of the arterioles from the deeper to the more superficial layers of the skin. In the illustrations given the chief characteristics of the cutaneous circulation in different areas of the surface and at different ages are easily seen. There appear to be three types of arterial supply in the skin: (1) Areas supplied by a single artery with little or no anastomosis with other vessels. This is frequent in the infant, where the development of the vessels is incomplete, and in the aged owing to senile atrophy, but occurs also in the adult in areas such as the back of the hand and foot, where circulation is not very active. (2) Areas where there is a fine arterial anastomosis, typically found on the face, the back, the palm, and sole of the adult. (3) Areas where there is a double anastomosis, both a dermic and hypodermic network of vessels. This arrangement is found in the scalp and the limbs. The book is well worth the attention of those who are concerned in the surgery of the skin, especially plastic surgery.

The forty-sixth volume of the *Transactions of the Edinburgh Obstetrical Society*[10] contains the papers read at the discussions during the session 1925-26, which were for the most part reported in our columns. The address of the retiring president, Professor B. P. Watson, dealt with the treatment of puerperal sepsis, and at subsequent meetings various communications relating to obstetrics and gynaecology were delivered. The volume contains an index, a list of office-bearers, a statement of accounts for the year ending October 31st, 1925, and a list of Fellows of the society.

A MEDICAL REVIEW OF SOVIET RUSSIA.*

V.—THE MEDICAL PROFESSION, SOVIET SCIENCE, AND SOVIET SANITATION.

BY

W. HORSLEY GANTT, B.Sc., M.D.

(Formerly Chief of the Medical Division of the American Relief Administration, Leningrad Unit.)

PART II.

SOVIET GOVERNMENT AND SCIENCE.

NOT being a student of politics, I have sought to omit reference to political questions, but as everything in Russia it under the strictest political control, it is not possible to do this entirely. Previously[1] I stated that the Soviets had done what they could, with their limited means, to foster the growth of science in Russia when this did not conflict with their political principles. This was my opinion from personal observations in Russia in 1922-23, and this remains my opinion in 1927, after two more years in the country. The political revolution has fallen, however, with crushing weight on many of the foremost doctors, and there are some who think that the Soviet régime *per se* has had a deleterious effect on science, in addition to the former economical chaos. A Russian scientist of international reputation (exiled in 1922) wrote me:

"My feeling is that the Soviet authorities have done what they could with their unlimited means of destruction to kill science and inhibit its growth because free and independent thinking is in direct conflict with the Soviet political principles."

An equally pessimistic view was expressed by a younger scientist of Leningrad in 1926, who, while admitting the Soviet efforts to benefit science, said that the psychological conditions were not conducive to scientific work—that the scientists themselves had been thrown into too prominent a social light, and that they were too dependent upon politics, the will of students, etc., and too uncertain as to the future. A world-famous physiologist complained in 1924 that the breadth of view necessary to scientific production was seriously threatened by the insistent emphasis upon allegiance to Marxian dogma in the present state of politics.

The life of the scientist has been harassed in general in the same way as that of other *intelligentzia* except for those whose eminence has brought them special privileges. I refrain from detailed discussion of this, just as I would from a discussion of the internal politics of any other foreign country. Many scientists seem to enjoy a special immunity, however, from political interference, and to have more freedom of speech and other privileges than any other class, including even the high politicians.

Numbers of the older physicians are unable to adjust themselves to the present political and social changes and would like to go abroad (chiefly to America).† State patronage is not new to the Russian physician, but many have been exiled or imprisoned by one régime or another. One doctor told me that he objected to living in Soviet Russia because he did not like the present uncultured students and people with whom he had to associate, although he was getting sufficient money to carry on his scientific work. Another reason for discontent is the inability to travel, not only on account of the lack of money, but because it is a tedious undertaking to obtain permission to leave Russia, and even more difficult for a Russian to get a visa for entering other countries. It is also economically next to impossible, as since April, 1926, a Russian must pay 220 to 440 R. (£22 to £44, depending upon his category) to the Soviet Government for permission to travel outside of Russia.

Among the younger physicians, however, there is much less dissatisfaction. This is to be expected from the change in the social status of the students. It is chiefly youths from those classes which have reason to be interested in the Soviet Government (workmen, peasants, and Communists) who have the opportunity to receive a medical education—or, in other words, the class from which opposition might come, the "bourgeoisie," were largely excluded from the universities two years ago.* The present system of education seems to ensure, for the immediate future at least, that all university graduates shall be in agreement with the existing form of government. The future professors and doctors must come from the classes who now have the opportunity for education—the so-called "Red" professors. Although some of the old professors fear expulsion from their chairs when a sufficient number of supporters of the new régime have been prepared to take their places, it does not seem likely from the past policy of the Soviet Government that they will expel an efficient professor for other reason than counter-revolutionary political activity. Even during the disorder of the revolution only a few were expelled.

A serious grievance is the difficulty of giving the children a technical or university education. In the Moscow universities in 1925 I was told there were 100 vacancies for the "bourgeoisie," and in Leningrad in the technical schools 80. Other sources of education are precluded by the absence of any but Government-owned universities.†

The circumstances following on the war and revolution have caused not a few to feel, as an author of a scientific treatise wrote, that "this is more the record of a broken and shattered life than of a profitable completion of physiological work." There are others, however, outside the Communist party, who look forward with more optimism to the future, and say that they have no political grievances, and that the Government is doing all it can to help them in their work. Typical of this group, an eminent non-partisan pathologist told me:

"The conditions in Soviet Russia are much better than they were in Tsarist Russia for scientific work. As Soviet finances increase more money is being given. The Narkompros (Minister of Education) is active in making scientific work more intensive and practical, as the Communists say that socialism can exist only with science. I think that scientists will be able to work entirely independently of politics, and will not be hampered in any way by political considerations. I know of many monarchistic professors who are now receiving large amounts of money to carry on their scientific work. As we have never had democracy in Russia, I cannot say what effect it would have upon science, but I think science will prosper more under the Soviet régime than under the Tsarist Government. My chief difficulty is learning to deal with the new type of student."

The director of one of the famous research institutes in Russia, also not a Communist, told me that the Soviet policy towards science in his institute had been constructive rather than destructive, and especially so during the past two years. Science is accorded a large place in the proletariat press, and scientific books are given an increasingly wide circulation in order to bring science to the door of the peasant and workman. More genuine respect is accorded scientists by the Government than to the members of any other profession I know of. The Soviet regard for science was shown by the celebration of the two hundredth anniversary of the Academy of Sciences in Leningrad (September 5th to 10th, 1925). The event was given full, first-page accounts in the Government newspapers. The delegates from all over the world were guests of the Government, and received more cordial and hospitable treatment than even political visitors to Russia. Among other privileges they were given free use of the railroads and hotels all over Soviet Russia.

Some excellent laboratories and new lines of research have been started by the Soviet Government. There are probably more scientific workers now than formerly, though

---

* Previous papers on medical and scientific work in Soviet Russia by Dr. Horsley Gantt were published in the BRITISH MEDICAL JOURNAL in 1924: I, A Review of Medical Education in Soviet Russia, vol. i, p. 1055; II, Hospitals and Health Conditions, vol. ii, p. 336; III, Scientific Work, vol. ii, p. 533. The first part of section IV, on "Change in type and incidence of disease," was published on August 14th, 1926, p. 303; Part II of this section was commenced on October 23rd (p. 747) and concluded on October 30th (p. 802). Part I of Section V was published on January 29th, 1927 (p. 198).

† I found this dissatisfaction also among many German physicians in 1923.

* See Lunacharsky, *The New University*, Moscow, 1924. Although many "bourgeois" students were expelled in 1924, most of these are being gradually readmitted; during the past year official opinion has become more liberal, and more emphasis is being placed on merit.

† A majority of the university students receive free tuition and a stipend that is sufficient to live on. Students are divided into categories (Communists, workmen and peasants, or their sons, bourgeoisie, etc.), and the amount they receive depends on this categorical classification; 10 to 20 per cent. of the medical students (40 per cent. of other students) are Communists. Those from the former "bourgeois" class instead of receiving a stipend must pay for tuition, unless they interest themselves in party politics. The percentage of workmen and peasants has risen from about 10 per cent. before the war to 93 per cent. in 1922.

they may not be so well prepared, and scientific work is being done in many new places. Among the best which the Soviet régime has initiated are the physiological laboratories for testing the effects of mineral waters and food at the various sanatoriums and health resorts, the Roentgenological Institute in Leningrad, and the Biochemical Institute of Bach in Moscow. They are models of their sort, and would be a credit to any country.* The most necessary equipment was bought (from Germany) in 1924, the first for ten years. Funds are being gradually increased, although in many places they are hardly back to the pre-war level. For example, the University of Moscow received 20,000 roubles in 1923, 200,000 in 1924, and 6,000,000 roubles will be given soon to carry out the first extensive repairs since the revolution.

The Soviet Government has not assumed a uniform attitude towards all laboratories, but has concentrated its efforts on the best. Some have received little or nothing for the past ten years; for instance, the Pathological Department of the First University of Moscow (the largest one there) has had almost nothing for eight years, and now receives only 160 roubles a month. However, these examples are rare, and will soon be things of the past. This laboratory has now been voted a large amount for the next five years. On the whole, work is progressing in spite of material difficulties. In one new institute in Moscow, for example, which I visited in November, 1926, I found the laboratory installed in a former stable; and the operating cloths covering the dog, and the caps and gowns which the doctors wore, were made of costly linen from one of the Tsar's palaces, having embossed on it the now forbidden and obsolete double eagle of imperial days. This conscription of stable and palace for the sake of the laboratory is typical, it seems to me, of the present scientific spirit in Russia.

In spite of the Soviet good intentions and efforts blunders have been made, which might be expected from a Government composed largely of workmen and peasants led by men who have inherited prejudices fostered by an oppressive Tsarism. For example, one might question some of the attempts to blend the political with the scientific, such as the following proposition of the State Scientific Council (Gosudarstvenyi Ootchenii Soviet) to the universities: that they shall submit applications for intended research eighteen months in advance to the committee, which will then decide whether the work is of value to the proletariat, and distribute problems among the laboratories to prevent parallel work. However, this ruling has never been put into effect.

The scientists themselves are left entirely to work out their scientific problems as they desire, as they did formerly. So far as I have been able to ascertain from two years' laboratory work in Soviet Russia, distribution of Soviet funds to laboratories and appointments to scientific positions are made according to merit rather than to politics. I have seen during the past year that some of the scientific laboratories whose heads are directly opposed to Soviet politics have received the greatest amount of money and equipment.

Politics does not often interfere with a doctor's having the position to which his abilities entitle him, except for administrative places, which are frequently given to party members. The heads of public health departments are usually Communists, and generally, judging from my experience, efficient organizers. In most of the scientific institutes there is a political commissar with certain administrative powers.

Present Conditions of Research Work.

From 1918 through 1922, as a result of the general state of the country, research work was done under appalling conditions and science kept alive at the cost of enormous energy and heroic sacrifices of the individual workers. During 1924 and 1925 the living conditions of the scientists, though still precarious, greatly improved, and the Soviet Government rendered considerable financial aid to science. Some laboratories have returned to normal, many new ones have been formed, and there are a few new institutes which surpass anything of their kind heretofore produced in Russia.

The spirit of research is prevalent, and is being fostered. Science will suffer during the next decade or so chiefly from the emigration of former scientists, the lack of preparation in the pupils of the war and revolution periods, the lack of adaptation between the professor and the present type of student, and from other inevitable adjustments to the new social conditions. The bringing of science under central control and Soviet patronage, though it may give a slight political colouring, is putting it on a much more stable financial basis than it was in old Russia.* The present position of science is, in my opinion, one of the most hopeful signs in Soviet Russia.

It is encouraging to hear the following ideals of the Soviet Government. It shows not only their interest in science, but their opinion of its relation to Soviet politics. As the future of science in Russia depends largely upon the Soviet attitude, I quote rather fully from the greeting sent to the Academy of Sciences on the day of its jubilee, September 5th, 1925—an event which was eagerly celebrated by the Soviet Government. It is signed by L. Kameneff and the president of the Central Executive Committee, Soviet Russia, M. Kalinine, and runs as follows:

"The October revolution has removed the social relations which had impressed their character upon scientific work and hindered its development. The social order founded on private ownership, exploitation, and national oppression provokes military collisions and retards the subdual of the forces of Nature by man. . . . The radical reorganization of social relations . . . cannot be solved without a development of science in all its branches. The Socialist Society is creating for scientific thought conditions of true liberty . . . Lenin's estimation of the services of science is the basis of the policy of the Soviet State.

"During the first hard years which followed the revolution, the Soviet power, forced to defend its existence . . . could not lend assistance . . . to the scientific work. Nor could it ensure to the scientific worker such conditions of life as are necessary for the productiveness of his work. . . . Science is international. . . . Only by the joint efforts of the scientists of all nations, and only by a constant and unremitting international intercourse between all scientists, can the development of science be promoted. The Government of the Union is ready to support all endeavours bending toward an active and wide international co-operation of all scientific workers."†

One can judge of the sincerity of these statements by the increased efforts recently made, and also by comparison with the official treatment of religion and the Church. This organization, which is considered a menace by the Soviet Government, has been as openly denounced as science has been advocated.

Scientific Work for Foreigners.

I shall add a few words from my personal experience concerning the opportunities for foreigners to do scientific work in Russia. During 1925-26 I have found the conditions quite favourable for research work; they have steadily improved. Clinically Russia has always been behind, and there is little inducement to do hospital work, except perhaps in a few special subjects. The greatest facilities are for physiological and to a less extent pathological work. Many admirable schemes have arisen in public health work and social hygiene under Dr. Semashko, which are well worth studying. The therapeutical effects of climate, mineral waters, baths, etc., are being carefully worked out in many parts of Russia.‡

The professors and instructors are cordial and hospitable to foreigners, and are eager to explain their work, and to be helpful. This Russian trait lessens the time necessary to become acquainted with the work of the laboratories. The Russians themselves very modestly attribute it to their habit of garrulousness. The extreme difficulty of the

* The new Brain Institute, opened in 1926 under Dr. Fursikov, for which 200,000 roubles have been given in Moscow, appears promising.

* For example, formerly the laboratory of Professor Pavlov at the Institute of Experimental Medicine supported itself partly by selling the gastric juice of the experimental dogs; now, in spite of the economic crisis in Russia, it receives the full amount that it needs.

† The fact that Lenin endorsed science has had a great influence, especially as Leninism has assumed somewhat the character of a State religion in Russia. In nearly every Government building (which includes most important buildings) is a room called "Lenin's Corner" (*ougolok Lenina*) containing all the writings of Lenin and his picture surrounded by his aphorisms. One of these says "Without science there is no communism" (Bez naouki nyet kommunisma"). I have seen this several times in laboratories and public buildings. The rooms are decorated in red and black, and there is an atmosphere of reverence which is strongly suggestive of the former chapels. It was due to Lenin's influence that Professor Pavlov was retained in Russia after the revolution.

‡ Details of some of the research work will be given in another article.

Russian language is obviated to some extent by the fact that nearly all educated Russians speak fluently either French, German, or English.

Although there are some irregularities in the curriculum compared with other countries, the informality and spirit of helpfulness make work pleasant. German methods and ideals as well as instruments have been most conspicuous, but the English language is being more and more studied in preference to German and French, and English and American literature has rapidly gained favour since the war, and now vies with German for first place.

After the stage of reciprocal suspicion is past, the Soviet officials seem kindly disposed towards a foreigner doing scientific work. He is admitted everywhere, and allowed to see almost everything. During the whole of 1925-26 I was never hampered nor had any special restrictions placed upon me. I found the officials usually willing to help. Foreigners working in the laboratories are not only treated with official respect, but they are exempted from certain taxes and given especial privileges.

There is one unfortunate obstacle in the way of foreigners entering Russia for research work, and that is the length of time necessary to obtain a visa. This seems to be greater for English and Americans than for other nationalities.* This is explained by the fact that political relations between the Government of Soviet Russia and those of other nations have been permeated on both sides by suspicion and ill feeling, sometimes almost equal to a state of war. As the president of the Society for Cultural Relations (Mme Kamenova, the sister of Trotsky) expressed it to me, the Soviet Government must judge each case on its merits, and assure itself that those who are admitted are at least not unfriendly and will not give false or exaggerated reports of Russian conditions. I hear, however, from Dr. Semashko's office (through Dr. Scheftel) that no one desiring to do scientific medical work in Soviet Russia has ever been refused a visa.

ATMOSPHERIC CONDITIONS IN COAL MINES.

ALIKE in its hygienic aspect as relating to the comfort and well-being of workers, and on its economic side as bearing on the question of efficiency, Report No. 39,[1] by Dr. Vernon and Mr. Bedford, to the Industrial Fatigue Research Board, is an important contribution to the study of industrial environment. The research it describes was directed to the investigation of the influence of atmospheric conditions on the working capacity and accident rate of coal-miners. Since the usual method of testing working capacity by a simple measurement of output cannot be applied to men hewing coal under widely varying conditions of ease or difficulty, it was decided to adopt two tests, a rest-pause test and a tub-filling test, as best calculated to discount these disturbing factors. The rest pauses referred to are the short voluntary rests from work which men engaged in heavy industries take every few minutes. Their duration and frequency afford a measure of the fatigue experienced. Involuntary rests, due mainly to waiting for tubs, were also taken into account. The tub-filling test is self-explanatory, but it may be observed that the tubs or trams have a mean capacity of 10 cwt., and that they are filled by both hewers and trammers, of whom the latter do haulage also.

The cooling power of the air was measured with kata-thermometers at 5½ ft. to 6 ft. above floor level. The dry and wet bulb temperatures were taken with Edney sling hygrometers, whirled at about 280 revolutions per minute. The number of men watched for an average period of 96 minutes each, at mean wet kata cooling powers ranging from 18.6 to 6.4, was 138. Their voluntary and involuntary rests were separately noted and their tub-filling times recorded. The resulting data are the actual working time per hour in minutes, the tub-filling time in minutes, and, dividing the former figure by the latter, the working capacity or rate of production, as exhibited in the following tables.

TABLE I.—*Working Capacity Based on Voluntary and Involuntary Rests.*

Mean wet kata cooling power.	Working time per hour in minutes.	Tub-filling time in minutes.	Rate of production.
18.6	52.7	8.0	52.7 ÷ 8.0 = 6.59 = 100
14.6	53.3	8.6	53.3 ÷ 8.6 = 6.20 = 94
12.9	51.0	8.5	51.0 ÷ 8.5 = 6.00 = 91
10.8	50.0	9.2	50.0 ÷ 9.2 = 5.43 = 82
9.0	48.9	9.1	48.9 ÷ 9.1 = 5.37 = 81
6.4	37.6	9.6	37.6 ÷ 9.6 = 3.92 = 59

TABLE II.—*Working Capacity Based on Voluntary Rests Only.*

Mean wet kata cooling power.	Rests in minutes per hour.	Tub-filling time in minutes.	Rate of production.
18.6	4.6	8.0	55.4 ÷ 8.0 = 6.93 = 100
14.6	5.1	8.6	54.9 ÷ 8.6 = 6.38 = 92
12.9	5.7	8.5	54.3 ÷ 8.5 = 6.39 = 92
10.8	5.5	9.2	54.5 ÷ 9.2 = 5.92 = 85
9.0	7.8	9.1	52.2 ÷ 9.1 = 5.74 = 83
6.4	10.6	9.6	49.4 ÷ 9.6 = 5.15 = 74

Table I, which includes both voluntary and involuntary rests, shows that at 18.6, with the highest cooling effect, the men worked 52.7 minutes to the hour, while at 6.4, the lowest, they worked only 37.6 minutes. Similarly, under the coolest conditions tub-filling took 8 minutes, under the warmest 9.6. The rate of production under the warmest conditions was 41 per cent. less than under the coolest. Table II, which deals with voluntary rests only, works out in the same sense as Table I, though the effect of adverse atmospheric conditions is not quite so marked.

The separate influence of air movement, which is a factor in cooling power as read from the kata-thermometer, was tested by selecting two groups of men, working at the same wet kata reading, but at mean air velocities of 15 and 51 feet a minute respectively. The low-velocity group showed rest pauses of 9.6 minutes an hour and a tub-filling time of 9 minutes. For the high-velocity group the corresponding figures were 7.8 and 8.6. The wet kata reading therefore in such cases does not tell the whole tale. It underestimates the importance of air velocity. It is, however, far more accurate than any other available index, such as the "effective temperature" recently determined in the laboratory of the American Society of Heating and Ventilating Engineers, Pittsburg, which includes a dry bulb temperature factor. For subjects of experiment at Pittsburg, doing light work and sweating little unless at high temperatures, the "effective temperature" index was significant; but the colliers of the report, doing heavy work and almost invariably streaming with perspiration, reacted to wet bulb temperatures only.

It was found that better facilities for air movement were afforded on the long-wall system of mining, in which the whole of the coal is hewn at once over a broad face, than on the pillar-and-stall system, in which headings are driven into the coal and supporting pillars left for subsequent removal. An important item is the distance of the brattice, or partition fixed between the intake and return airways, from the working face. The nearer the brattice to the face the greater the air velocity at the face and the lower the wet bulb temperature. Too great proximity, however, producing a continuous draught on the bare backs of the colliers, may cause rheumatism.

The results obtained were examined also in their relation to accident rates in coal mines and the general health of miners. The view is expressed that on the data available adverse atmospheric conditions increase the accident rate and impair general health, but that further research is required to confirm these findings, which, are, in the meantime, more or less provisional.

* In my case it was necessary to wait four months for the visa after having the recommendations of Professor Pavlov and both American and English medical authorities. For every other country of Europe, excepting three to which I did not apply, I received the visa the same hour that I asked for it.

SATURDAY, FEBRUARY 5TH, 1927.

THE EPILEPSIES AND LIFE ASSURANCE.

DR. S. A. KINNIER WILSON'S address on the epilepsies and life insurance, delivered before the Assurance Medical Society, and printed elsewhere in this issue (p. 221), reminds us of the great changes that have come over our conception of epilepsy. After centuries of masquerade as a disease epilepsy now stands among the symptoms. Those whose student days lie twenty to twenty-five years away will recall how well defined a disease it was considered then, in the schools at all events, and how glibly its dramatic and blessedly remembrable manifestations came tripping from the tongue. But time and observation have undermined and dethroned, and even dismembered it. So now we have "the epilepsies"—a bundle of symptoms of great variety, but linked by their common affinities with the stigmata of the now extinct disease. Sometimes the symptom has an assignable cause—say, cerebral tumour, or syphilis, or uraemia—and thereby ceases to be epilepsy. But even when no cause can be assigned the symptom is no longer by that default accounted a disease. It remains but a symptom, for which a cause must be sought or guessed or inferred. This unassorted residue still figures, it is true, as "idiopathic epilepsy," which now is a way of saying that we have detected the disguise but have not as yet identified the wearer of it.

This conception of epilepsy has certainly rid the term of some of its more sinister connotations, for under it the graver organic affections which are liable to express themselves in epileptic guise are relegated to their proper pathological category, and we are left with those instances which for the most part are the expression of something subtle enough to leave no trace on structure. What exactly that "something" may be is a question that still lacks an answer, and is likely to get it (when the time comes) piecemeal and case by case. Dr. Wilson's conclusion is that "healthy neural mechanisms may become epileptogenous without being in the remotest degree diseased," and most practitioners will be able to find support for this view among their clinical recollections. Certainly we find many causes—as, for example, digestive upsets or the poisons of microbic invasion—which are capable of precipitating convulsions in babies whose nervous systems are apparently undamaged; and it does not strain the imagination to conceive that comparable explosions may be excited in healthy adults by rare conjunctions of favouring events—psychical, biochemical, microbic, or what you will.

Along such lines it is possible to explain away reassuringly the occasional epilepsy, the isolated fit or "faint," or the half-dozen similar seizures scattered at haphazard throughout a lifetime of otherwise average health. These are the "benign" idiopathic epilepsies in respect of which Dr. Wilson pleaded for leniency from his audience of insurance examiners. It is probable that he was preaching to the converted, but his peroration shows that, so far from being aware of this, he was already resigned to failure in his preaching. "I do not hope," he says, "to be able to do more than disturb a little the preconceptions of any who, accepting precedents and traditional practice, refuse proposals coming from "epileptics" of any kind or degree. Ideas dating from a less knowledgeable era have had so long a start that one doubts if they will be overtaken. Hughlings Jackson once said that it takes twenty-five years for new conceptions of disease to penetrate the mind of the profession, and if this is needlessly cynical, it at least embodies an element of truth." To probe the general justification for this gentle and even compassionate remonstrance would be an inquiry not without interest, for there is a good deal to be said on the other side, if we may judge by the high rate of infantile mortality among new conceptions in medicine. But for the present we may confine ourselves to its bearing upon the audience to whom it was spoken.

It is a curious circumstance that when those who have no special acquaintance with the medical aspects of life assurance address themselves to the subject, they are soon to be found grumbling good-humouredly because this branch of medical practice is so much behind the times. This has been observed on several occasions and in several contexts. When doubts first began to be cast upon the importance of albuminuria the medical advisers of life assurance companies evinced no haste to alter their practice of regarding it with grave suspicion. When, upon the introduction of salvarsan, the cry went up that syphilis could now be cured in a few days, again the insurance world remained unmoved. When it was announced that renal glycosuria was not more pathological than red hair or a Roman nose, insurance examiners once more showed no undue elation, and in all these cases were reprehended for their obsolescence. Now it is the turn of epilepsy. What is it that lurks behind this phenomenon?

The key to the enigma appears to lie in nothing more profound than a variation in point of view. The clinician, interviewing a patient in his consulting room for the purpose of restoring his health, will naturally minimize ominous possibilities, in so far as he can do so without prejudice to his patient; he will make what play he can with pronouncements that carry a message of good cheer for the sufferer, however much in his heart of hearts he qualifies his own acceptance of them. He will, in short, give his patient the benefit of every doubt. And how many doubts there are! But the examiner who is acting for an insurance company owes his allegiance elsewhere, and the benefit of his doubts goes to the company he is serving. He awaits, that is to say, a completer conviction concerning new conceptions than would suffice to make him enlist them in his service for purposes of healing. And so it is, we suspect, that, having earned the reprobation of Dr. Wilson by the advice he has given in the City, the insurance medical examiner will do his best to rehabilitate himself by putting a contrary complexion upon a similar case when he meets it in his consulting room. No doubt the usage accorded to invalid lives will be found to vary somewhat from office to office, but on the whole we fancy it will be found to keep step pretty well with the sedate paces of established knowledge, if not with the Charlestons and high jinks of day-to-day discovery.

THE NURSING PROFESSION.

Sairey Gamp is dead: her line is ended: she has left no descendants. There were good nurses before her day, and in her day; for the instinct of motherliness is an attribute of the feminine heart, and it finds expression in bringing ease to the uneasy. But there is a sharp line of cleavage between the nurse of the not far distant past and the nurse of to-day. It is no mere change of fashion, but a fundamental change in attitude. The old nurse was a nurse from inclination or accident; she may have had a "gift" for the work, a gift polished by use, but that was all. The modern nurse has something more. She is trained and disciplined; selected, shaped, and refined by knowledge and outlook. A good modern nurse is wholly feminine, full of vitality, ordered in service, faithful and unweary in well-doing, a fine responsive devoted instrument, willingly placed in the hands of Medicine for the service of the sick. This is all common knowledge, but it may be well to remind ourselves of it sometimes.

But when we come to review the position of trained nurses to-day the question arises, Does society give the individual nurse a fair deal? Society pays willing tribute to the service of the nurse. She has never before stood higher in public esteem and affection, and if status is everything, then, according to Mr. Ramsay MacDonald, who opened a recent conference on "The nursing profession" (reported at page 253), nurses should be among the happiest of mortals. But prestige is not enough, nor a banner emblazoned with the image of Florence Nightingale or of Francis of Assisi. These are proud possessions, and a great stimulus to devotion; but food and other material things, and the amenities of life, are as necessary to her well-being. It is almost true to say nurses have had too much of status and too little of stuff in recent days. The earlier of the new nurses were so devoted, so much absorbed in their mission, and so often blessed with some private resources, that they gave no thought for the morrow, or for their innumerable successors who must needs live by their work. Happily in the last score of years much of this neglect has been remedied. The indispensable work of the trained nurse has been recognized by the State. There is a General Nursing Council representative of all interests, with a register growing in volume, and the nurses have their own organizations which take a motherly interest in their collective and individual affairs.

The General Nursing Council is comparable to the General Medical Council. Both supervise education, place accredited candidates on a register, and keep the names of the registered there so long as they are worthy. There is a College of Nursing, which is comparable to the British Medical Association, for both are voluntary societies supported and controlled by the individual members of these societies. It is estimated that there are something like 100,000 trained nurses in the country; of these, 61,000 have taken advantage of the voluntary registration provided by the State. The College of Nursing, founded in 1916, has now a membership of 25,000 fully trained registered nurses, and a Student Nurse Association with 1,400 on its roll. The subscription to the college is small, so an endowment is needed of £100,000, and of this sum over three-fifths is in hand. The college has a fine headquarters by Cavendish Square, with a club adjoining (with separate membership), both buildings the gifts of Lady Cowdray. There are local branches with appropriate organization all over the country. The management is in the hands of the council of the college, which is directly nominated and elected by the postal vote of the members. Its work and aims follow very closely those of the British Medical Association. The honour and interest of the nurse are the care of the college. To this end it concerns itself with her education, and provides facilities for post-graduate study. It is convinced that the status and advancement of nurses depend upon the quality of their education. Good education means good nurses, good status, and good pay; indifferent education, the reverse. The college is ever on the alert in the scrutiny of the terms of service offered by employers of nurses, particularly by public bodies, co-operations, and hospitals. It has drawn up standards of pay which are such that self-respecting employers generally might well take note of them. It now controls the leading nursing journal, the *Nursing Times*, and through this official organ is able to exclude many undesirable advertisements—a most effective mode of bringing wisdom to the ignorant. Further, the college maintains a good library, a loan fund to assist members desiring to take up special training, a sickness insurance scheme, two convalescent homes, and a legal aid department. A quarterly bulletin is issued free, but subscription to the *Nursing Times* is extra. The college has taken a foremost part in devising the scheme for nurses' pensions which is now under consideration by many hospitals; no fewer than eighty-six London hospitals have approved it and propose to adopt it. Under that scheme the nurse provides contributions of 5 per cent. and the employer of 10 per cent. of the pay, the pension becomes payable at the age of 55 years, and if more than five annual contributions have been made these are returnable before the age of retirement if the service be left for any reason, such as marriage. The policies are transferable with the nurse from one employment to another, so that there is no check on mobility.

Such an organization as this affords some proof that the nurses are not friendless, and since the management of the college is in their own hands they are not helpless. This, however, is scarcely the conclusion that emerges from the recently published report of the Labour party on "The nursing profession," which was submitted to last week's conference. The report is largely filled with data that can be and probably were extracted from well known documents. Of new information there is little. Indeed, in the opening paragraph we read: "On such incomplete data only the most tentative conclusions can be drawn, and no attempt has been made to paint an exact picture for the country as a whole." This is unfortunate, and it would appear to be due in some measure to the fault of those who drew up the document, for we understand that the College of Nursing (and its public health section), which is most likely to know about these things, was not represented at the meetings at which the report of the Labour party was drawn up. This report directs attention to inequalities of conditions of employment, but nowhere seems to appreciate that the root of the evil is inequality of training—a fact insisted upon by the college. The cure for all the ills of the nurses is, according to the Labour party, the formation of a trade union. Is this really so? It seems to be assumed as an axiom in the report. But we find in it no evidence of how the nurses would benefit by a change from their own college to a trade union, presumably affiliated with other bodies of unlike trades. It is said that one section of nurses are trade unionists: "Nurses in mental hospitals are strongly

organized, belonging largely to the National Asylum Workers' Union, an organization with 11,000 members, all of whom, however, are not nurses." Inquiries as to the actual number of nurses in this union failed, however, to secure the desired information. But there is a Professional Union of Trained Nurses with a membership of 460; that its membership is so small is perhaps explained by a naive confession in the report: "Unfortunately, owing to the tradition of the profession, the average nurse thinks of a trade union as a body of manual workers continually taking part in strikes." We scarcely think that the events of the past year will have done much to correct this impression. So far we have only noticed the chief professional organizations of the nurses. But there are other bodies. There is the Royal British Nursing Association, which is mainly social and provident in character. There is also a new British College of Nurses, lately formed with a large endowment given by an anonymous donor; but so far we have not heard of any action by this body.

The nurses would appear to have enough organizations. If these pursue their avowed aims—better education, better terms of service, and satisfactory pensions—the material conditions of the nurse, and therewith her status, will be advanced, so long as the individual nurses continue to display that devotion to the sick which is their hall-mark. We agree with the College of Nursing that education comes first. It certainly killed Sairey Gamp and gave birth to the new nurse.

SIR CLIFFORD ALLBUTT.

AMONG the problems of the day in which Sir Clifford Allbutt, as a general physician, took a lively interest was the nature, treatment, and control of tuberculosis. He began medicine at a time when a reasoned belief in the infectious nature of consumption rested mainly on the impressive but rather crude experiments of Villemin; he was still in middle life when Koch established the specificity of the bacillus. He observed the attempts to apply the specificity in therapeutics, and he watched the efforts to control it by public health methods and by sanatoriums. It was characteristic of the freshness of mind he retained in old age that his name is perhaps best known, in this connexion, for the practical interest he showed in one of the latest schemes. From its origin in the war-clouded year 1916, the tuberculosis colony at Papworth received his active support, and he presided over it through its early period of difficulty and its later growth in size and popularity. At first the needs of tuberculous ex-soldiers dominated the scheme, and the growing realization of the possibility of re-establishing in the tuberculous some degree of economic efficiency was a source of keen satisfaction to him, contrasting as it did with the hopelessness which inevitably attached to the disease in previous years. When the Sims Woodhead Memorial Institute of Research was opened at Papworth in 1924, something of the intense interest Sir Clifford Allbutt felt found utterance in his eloquent tribute to one who had shared with him the burden which attended the institution of the scheme. We publish elsewhere in this issue (p. 259) a letter signed by a number of distinguished friends of Sir Clifford Allbutt interested in the Papworth colony, announcing that it has been decided to erect to his memory two new cottages in the colony; he was president of the colony, and the form of the memorial would, we feel sure, have pleased him, since it will still further increase the benefits afforded by an undertaking which, during his later years, was very close to his heart.

THE PRESIDENT ON HOSPITALS.

IN the SUPPLEMENT this week we print in full the address on voluntary hospitals and their future which the President of the British Medical Association, Mr. R. G. Hogarth, delivered last Sunday at Nottingham. It was given to laymen, and to judge by the wide quotations therefrom that have appeared in the newspapers on the days following its delivery, the address most certainly caught the ear and the mind of his audience. It will be no less arresting to the medical reader. As a lecture it is an example of felicitous phrasing, abounding in touches of wit and humour and human sympathy, yet full of a wisdom that is born of wide knowledge of hospital affairs. The Nottingham Hospital Sunday Fund authorities did a shrewd thing when they invited Mr. Hogarth to address their supporters, and Mr. Hogarth rose to the occasion in a most happy manner. His words read well, and they must have been better still in the hearing, for our President, as all who attended the Annual Meeting of 1926 know, can speak as felicitously and plainly as he can write. The theme of the address is one that is near to the heart of very many of our countrymen, both professional and lay. After long years of noble service given by the voluntary hospitals throughout the country, it looked for a time in the past few years as though their day was done. Doughty champions of the voluntary hospitals seemed for the moment to lose heart, and some who had been giants in their day showed by their words that they were ready to throw up a work that had become too heavy for them, and turn the trusteeship of the heritage of these hospitals and of their future guidance over to the mercies of statutory bodies. For the moment they forgot that wisdom would not die with them, and that they were likely to have successors capable of emulating or surpassing the finest achievement of their earlier and more robust days. Happily the fears of the faint-hearted are being dispelled by events. The rebound from pessimism has been as emphatic as it well could be. The voluntary hospitals are re-established upon a broader basis than ever before—a basis that is the more secure since it is carried no longer solely upon the shoulders of sympathizers among the middle and comfortable classes, but now also on the broader backs of the more numerous and regular contributors who form for the most part the clientele of the hospitals. That these regular contributors are forthcoming, and in such volume, is sure evidence of the public appreciation of the work done and yet to be done by these hospitals. The new attitude is full of promise for the future. Certainly it brings its own particular problems—problems that affect our profession very nearly. But these have been foreseen by the members of the British Medical Association, and the mode of meeting them has been worked out in detail in the Hospital Policy of the Association. There is evidence that this policy is attracting increasing attention both by medical staffs and hospital boards, and by laymen generally, just because it indicates with some degree of accuracy the lines upon which development is taking place and satisfactory methods for attaining a fair and just balance as between all the parties concerned. We congratulate Mr. Hogarth on his address, and on the wide publicity it has received. We also hope that there will be many members of our Association who will follow his example and address themselves to similar audiences. Throughout the country there are numberless members of "Brotherhoods," meeting on Sunday afternoons, who are generally happy to hear a doctor speak to them on Hospital Sunday. Nothing but good can come of public enlightenment in this matter of the hospitals, and we feel sure that when the public does appreciate the facts of the case fears that the voluntary hospitals may be benumbed by the heavy hand of officialdom (a danger which Mr. Hogarth rightly refers to) will be dispelled; and the

place of the voluntary hospitals as hospitals for all—for the poor, for the workers, for the middle-class professional workers, and even for those in "comfortable circumstances"—will be assured in any new scheme of health organization that may come through the recasting or rejuvenation of our hoary-headed Poor Law system.

THE PHYSIQUE OF WOMEN IN INDUSTRY.

THE results of an inquiry, undertaken at the request of the Medical Research Council, into the physical condition of a large number of industrial women workers were detailed by Professor E. P. Cathcart, F.R.S., of Glasgow, in the Friday evening lecture at the Royal Institution on January 28th. Dr. Cathcart said that he and his colleagues had attempted to determine by physical measurement the size, weight, and strength of women in industry, what load or weight a woman could carry without physiological disturbance, and in practice what loads were actually carried by women in the factories. For the purpose of the inquiry just over 3,000 women employed in factories were selected, and, as a check on these, over 400 others who had worked in factories but had been out of employment for a long period. Another control group consisted of 500 healthy young women in training at the college for teachers in Glasgow. The strength of the great muscles of the back and legs was tested by a pulling-up movement; the grip was also determined, and the capacity for a crushing forward movement. The first of these tests, the lifting movement, was similar to a repeated movement carried out by many of the women in their ordinary employment; the grip also was an exercise they were constantly called upon to make, but the crushing test was somewhat singular in that it brought into play a large number of muscles which were not used in factory routine. The women examined were taken from all types of industrial occupation. The heaviest work noted was carried out in chemical works at Glasgow and brickworks in the Midlands, and scarcely less severe was the work of women in the bolt and nut trade, the trade in hollow ware, and certain industries of the Potteries. A great deal of the occupation of women, however, amounted to little more than machine-minding, which was not arduous in the demand it made upon the muscles, though, of course, it required skill, and, in the case of high-speed machinery, alertness of mind and marked quickness of fingers. Dr. Cathcart regarded the girls employed in the chemical works at Glasgow, all of them over 16 years of age, as the most perfect specimens of young womanhood in industry from the point of view of physique and grace of carriage. The astonishing thing was that these young women had been born and bred in the slum districts of Glasgow, and that the great majority of their mothers and grandmothers had done the same kind of work before them. As illustrating the strenuous nature of the work undertaken by these women, Dr. Cathcart said that he had watched one of them in the chemical works move from 20 to 25 tons of raw material in a day, lifting her shovel to a height of 2½ feet. In brickworks, again, the physique and carriage of the girls were excellent. Girls carrying bricks were allowed to select their own load, which, as a rule, was over 100 lb. at a time, and was carried a distance of from 70 to 80 yards. Women conveying bricks in barrows took normally loads of from 4 to 4½ cwt. Thus, on the whole, it seemed that the factories in which hard work was done were those in which the women engaged possessed the best physique and carriage. The figures given showed that about half the women engaged in industry were between the ages of 17 and 22. Towards the latter age large numbers of them left the factory on marriage, exchanging one servitude for another, perhaps a worse! The 3,000 women examined represented, of course, but a small proportion of the total number engaged in industry, and it had been suggested that the fact that the great majority of them were young women was due to the reluctance of older women to come forward for measurement. Dr. Cathcart admitted that that might be a factor, but he did not believe that it played any large part. The average weight of the women examined was found to be 109 lb., the average height 62 inches, and the average pull of the body upwards 183 lb., the grip 58 lb., and the crushing power 50 lb. The ages of the group of 400 women no longer employed in the factories ranged between 19 and 55; in average weight there was practically no difference between them and the employed women, though in other respects there was a certain inferiority. If weight were taken as a criterion of nourishment, then employed and unemployed were equally well nourished; but what most markedly differentiated the unemployed from the employed was the figure obtained when the "total strength" was divided by the weight. That raised the question whether these women who were no longer in the factory had become undernourished and out of practice for their work. Dr. Cathcart thought the fact was simply that many, not all, of these women were disengaged because when they applied for work they were found not to be of the type of physique the employer of labour wanted. There was no question of their getting out of practice, for they did hard housework, which was of a more strenuous nature than that entailed in the majority of industrial processes. The control group, consisting of girls in training as teachers, drawn from all parts of Scotland, and ranging in age from 18 to 22, were in height, weight, and strength markedly above both the other groups. It had to be asked why girls living relatively sheltered lives were so much stronger and physically so much more capable of effort than their industrial sisters. The girls in the Glasgow training college did not come from affluent families, but at college they lived on a large open estate, where the conditions were very good. On entrance they underwent a medical examination, so that they were really picked women, and during their training their physique was carefully looked after; they had physical training, and, of course, played the ordinary outdoor games. To what extent, then, did strength depend on muscular equipment? Dr. Cathcart was of opinion that it was really not a question of physical training so far as these college women were concerned. They were being mentally trained at the same time, and the consequent mental alertness they acquired played a very large part in their power of co-ordinating their muscles. This, possibly, was one of the factors which accounted for the very marked difference between them and the industrial groups. He suggested that a possible test of fitness for industry might be found in the number of pounds representing the total strength divided by the body weight. If the quotient was below 2.5 he would be inclined to say that the person was unfit for hard, active work in a factory. Altogether the inquiry, although of relatively small compass, has supplied information relating to women factory workers which has hitherto been sadly lacking.

ELIAS ASHMOLE.

MR. R. T. GUNTHER, the historian of Oxford science, continues his labour of love in editing *The Diary and Will of Elias Ashmole*,[1] the son of a Lichfield saddler, whose crowning achievement was not, as he probably would have said, his *History of the Order and Institution of the Garter*, but the founding of the first public museum of natural history in Britain. His diary was printed twice in 1717 and again in 1774; it now appears with his will, dated September 6th, 1686, some six years before his death at the age of 76, with some additional papers, interesting notes,

[1] *The Diary and Will of Elias Ashmole.* Edited and extended from the original manuscripts by R. T. Gunther. Old Ashmolean Reprints II, Oxford. 1927. (Fcap. 8vo, pp. 183; frontispiece and 2 plates. 7s. 6d.)

and a preface by the editor, which we could wish was longer. The Diary, entitled "The Life of Elias Ashmole, Esqr.; in the way of Diary; written by Himself," contains many medical details—for example, "I had the small-pox (yet but few) as also the swine-pox and the measles."; the entry "I took my usual sweat" often occurs, and is the last in the Diary. He was attended for a time by the famous Thomas Wharton the anatomist, but in 1673 notes that after the onset of left hemiplegia, and three days before his death, Wharton sent for him at midnight, "and because some differences had formerly fallen out between us, desired to be reconciled to me, which he was." In 1651, or twenty-two years earlier than this last meeting, he writes that after "a surfeit occasioned by drinking water after venison . . . Mr. Saunders the astrologian sent me a piece of bryony root to hold in my hand, and within a quarter of an hour my stomach was freed of that great oppression, which nothing which I took from Dr. Wharton could do before." For nearly two centuries the original Ashmolean Museum in Broad Street, a picture of which is finely reproduced in this volume, was one of the treasuries of Oxford, for it contained the collections of the Tradescants, where natural science and the history of science could be quietly studied; but the editor laments that in the scientific onrush of the last century these historic collections were dispersed, and during the first quarter of the present century the building, the finest and most venerable museum building in Britain, remained derelict. It is opportune, therefore, that now, when the old Ashmolean building has been reopened for the collection of scientific instruments, which the editor has so long and so successfully laboured to perfect, he should mark the occasion by presenting us with this interesting and intimate record of its founder.

PHYSIOLOGY OF THE CLIMATE AT HIGH ALTITUDES.

A FEW years ago Professor A. Loewy was appointed director of the new Swiss Research Institute at Davos for the study of physiology and of tuberculosis at high altitudes. He has just published a review[1] of the recent researches concerning the physiology of the climate at such altitudes. He records therein the results of the researches of his colleagues and himself during the short period they have been at Davos, in addition to results of researches from other parts of the world, such as are given in the reports of the Everest expeditions and of the expedition to Cerro de Pasco in the Andes undertaken by Professor J. Barcroft and his colleagues; reference is made also to the work of Professor J. S. Haldane and his co-workers. The review deals not only with the effects of low oxygen pressure in the air, but also with the effects of increased radiation from the sun at high altitudes, to electrical changes in the air, and to changes in atmospheric cooling power, attention being directed to the work of Professor Dorno at Davos and Dr. Leonard Hill in England. The physiological and pathological changes observed centre round those produced in the heart, the blood, the respiratory system, the liver, and in the skin. It is difficult to draw definite conclusions from many of the researches, because different subjects present quite different reactions. At present no published explanation of the processes underlying the effects of high altitude, nor of those concerned in acclimatization, can be accepted without considerable reserve. The important researches of Dr. Argyll Campbell, which are now appearing in the *Journal of Physiology*, are clearing up many controversial points. These researches show that oxygen want is the one essential cause of the symptoms of altitude sickness, and that acclimatization depends on the faculty of the body to keep up the supply of oxygen to the tissues, mainly by alterations in respiration and in the blood. He finds no evidence in favour of Dr. Haldane's theory of oxygen being secreted inwards by the pulmonary alveoli. Dr. Loewy is in favour of the theory that certain protein bodies are the substances responsible for the changes observed, and he points out that injections of protein substances produce chemical, physiological, and pathological effects resembling closely those observed at high altitudes. The review contains much of interest and importance to clinicians and pathologists as well as to physiologists and hygienists, who are more directly concerned.

[1] *Ergebnisse der Hygiene, Bakteriologie, Immunitätsforschung, und experimentellen Therapie*, Vol. VIII, p. 311. A separate print of the article is published with the title *Der Heutige Stand der Physiologie des Höhenklimas* by the firm of J. Springer, Berlin, price R.M. 3.60.

PARASITOLOGY.

PARASITOLOGY is one of the subjects which are fast leaving the care of their foster-mother, tropical medicine, and, a sturdy adolescent, is taking its proper place in the general medical world. This important advance was recognized in the rearrangement of the medical curriculum some few years ago, and one of the signs of the times is the completion of the fourth volume of the *Journal of Helminthology*, edited by Professor R. T. Leiper and published at the London School of Hygiene and Tropical Medicine, 23, Endsleigh Gardens, W.C.1, in quarterly parts (annual subscription 25s. net a volume, post free). Like the three previous volumes, the articles are in the main morphological—for morphology must be the basis of all the zoological sciences, just as it is in medicine. But there are many articles of more than passing medical significance, including a full examination of the serological methods for the diagnosis of hydatid disease, by Miss I. Hiles. In addition to a detailed survey of the literature of the complement fixation test, Miss Hiles describes a method by which "stock" antigen can be prepared from dried scolices and kept for some time in the laboratory for use on occasion. Hydatid disease is not very uncommon in Britain, and, as there is sometimes a difficulty in maintaining a supply of fresh animal material, it is a very desirable advance in technique to have an antigen always on hand for immediate diagnosis. Another article of considerable interest is by Professor Khalil of Egypt, who shows that the well clothed and well shod Egyptian policeman steadily, throughout a period of years, loses those parasites with which, when he joined the force, he was infested. This article affords good evidence of the value of clothing and discipline as measures of personal hygiene in parasite-infested countries. Other articles of direct medical interest are on *Physaloptera*—an ascaris-like worm common in man in East Africa—and on the adults of the genus *Echinococcus*, the larval forms of which are the hydatid cysts; while less directly medical, but having an importance of their own, are observations on related parasites in animals and plants, on their morphology, nomenclature, life histories, and distribution. Parasites are described from all parts of the globe and from most of the various groups of the animal kingdom—bald statements which may serve to indicate the catholic nature of the work which is appearing in the *Journal of Helminthology*.

HOSPITAL ALMONERS.

THE Joint University Council for Social Studies has issued a most valuable report on "Training for hospital social work." The chairman of this council is Mr. Frank Tillyard, professor of commercial law and dean of the Faculty of Commerce in the University of Birmingham, and a preface is written by Mr. A. M. Carr Saunders, Charles Booth professor of social science in the University of Liverpool. Until late in the nineteenth century no effort was made to check the abuses of the out-patient departments of hospitals, crowded as they were by an unselected

mass of patients. Nothing was done for them by way of after-care save what little the chaplain or matron could effect. King's College Hospital in 1876 appointed an inquiry officer with intent to keep out unsuitable patients and to refer them to their home doctors. St. Bartholomew's followed suit in 1883, and the London Hospital a year later. The first move in the right direction came from the late Sir Charles Loch, the secretary of the Charity Organization Society, which, though it is often condemned for hardness of heart, does most valuable work. The untouched field for constructive work seemed to him to be more important than the abuse and misuse of out-patient treatment. He wished to see the needy helped to carry out the treatment ordered, to prevent the abuse of a charity by those who could pay, and to be able to arrange for transfer to the Poor Law authorities where that was the most effective method of dealing with the patient. These three main heads still form the basis of the almoner's work, though its ramifications have become vastly more extensive. The first real hospital almoner was appointed by the Royal Free Hospital, where a secretary trained by the Charity Organization Society began work in 1895; for some time part of the almoner's salary was paid by the society. Most hospital almoners are women, and their talent for gentle but searching inquiry is often quite remarkable. Their first duty is to discover the patient's home conditions so that the hospital medical officer may know what he is dealing with, and then to see that the directions for treatment are carried out. They have to organize after-care for in-patients; to know all about State rights and State duties in every matter of health that can affect a patient; to discover what contribution should be made to the funds of the hospital and to get it; to check abuse by patients who can pay; to turn aside insured persons not requiring special hospital treatment and those who would be better served by statutory provision; and to administer Samaritan funds. Such an officer needs careful training, however much inborn aptitude there may be. There is now such a scheme, promoted in London and some provincial centres. Two years' training is necessary—four months' whole-time work in the office of an efficient charity organization society, nine months' college study in economics at a university college, and eleven months' practical work under the direction of an almoner at a hospital recognized as a training centre for almoners. The successful candidate cannot be accepted for independent work until the age of 22. One passage in the report, though not new in substance, seems worthy of quotation here, if only because it is written by laymen and endorsed by trained economists: "The service rendered by the medical staff to the patients who flock to hospitals is not, and cannot be expected to be, adequate to their needs. The individual patient at the hospital appears for the moment as an isolated social unit with some bodily ailment which needs correction, but the very thing which brings him there is upsetting the balance of his social environment and making fresh difficulties in an already difficult life. The doctor cannot attempt to deal with these added causes of friction. . . . We believe the time will come when no modern well equipped hospital for the treatment of any form of disability will be without its social service department, staffed by fully qualified almoners."

INFLUENZA.

In the week ending January 29th deaths from influenza in the great towns of England and Wales increased from 470 to 725, and in London from 197 to 252. The rate of increase in London is slackening considerably, and it is probable that the maximum of the epidemic there will soon be reached, if it has not already been reached. But elsewhere there has been no similar diminution of the rate of increase, so that we can hardly expect that the number of deaths recorded last week will not be exceeded.

CERTIFICATION OF THE FACT OF DEATH.

It was mentioned last week in Current Notes (SUPPLEMENT, p. 34) that the Registrar-General had issued instructions to registrars defining the procedure they should follow on receipt of a death certificate of a person who had not been seen by a doctor within fourteen days of death. We are indebted to the Registrar-General for the following additional information with regard to the regulation on this matter issued by him under date December 31st, 1926. It imposes the following requirement upon registrars of births and deaths.

"Where the contents of the medical certificate show that the deceased was not seen after death by the certifying practitioner, and was not seen alive by him within fourteen days of the date of death, the death should be reported to the coroner by the registrar."

To this new regulation the following instruction is appended:

"In the case of all medical certificates given on the new official form bearing serial numbers with the prefix 'Y' the certificate will clearly show whether the deceased was seen after death or not. In the case of a certificate given on the forms previously issued with the prefix 'X,' or any older form, the omission of the words 'as I am informed' from the blank in the relevant portion of the form is to be taken as meaning that the practitioner saw the deceased after death and is thus prepared to certify from his own knowledge that death took place. But if the registrar has any reason to suspect or believe that the omission was not deliberate, but was due to inadvertence, he should make inquiry of the practitioner in any case where the deceased was not seen alive within fourteen days of death."

We are also informed that the Secretary of State has recently called the attention of coroners to this regulation in a circular letter which contains the following observations:

"The regulation is based upon the view that responsibility ought not to be accepted by the registrar for registering the fact and cause of a death on the evidence of a certificate given in the circumstances indicated in the regulation unless he has previously given the coroner an opportunity, at any rate, of investigation or inquiry.

"When a certificate of death is referred to the coroner under the new regulation, two points may arise:

(*a*) what proof is there of the *fact* of death—that is, what proof is there that a *body* is lying within the coroner's jurisdiction?

(*b*) is the *cause* of death sufficiently established, or is investigation by the coroner required?"

The Registrar-General is of opinion that the first point can be cleared up in various ways, according to circumstances. In some cases the coroner may consider it desirable or necessary to ask the doctor why he has not seen the body, and to request him to see it in order that the doctor may amend his certificate in that respect. We are advised, however, that there is no statutory obligation on the doctor to comply. If it is impracticable for the original certifier to see the body, the coroner in parts of the country where the schedule made by the local authority enables payment for such a service may, in the Registrar-General's view, upon sufficient occasion, ask another practitioner to see the body and report to the coroner as to the fact of death, and, if necessary, also as to the cause of death. In many cases it may be found upon view by the coroner's officer, in the course of his inquiries, that the fact of death is painfully obvious.

As regards the second point, the necessity for investigation, it is for the coroner to decide whether the circumstances are such as to require investigation by him having regard to the duties imposed upon him by law. The mere reference of a certificate to the coroner by the registrar does not of itself set up an obligation to investigate. Such reference is only one of many means by which a coroner may have his attention drawn to a death and to the possibility that action by him may be necessary. It is open to a coroner to decide at once to inform the registrar that in his opinion no inquest is necessary, or to institute such inquiries and obtain such information as he may think requisite before deciding whether to inform the registrar as above or whether to hold an inquest.

THE NURSING PROFESSION.

CONFERENCE SUMMONED BY THE LABOUR PARTY.

A CONFERENCE of nursing and kindred organizations, summoned by the Labour party, was held at Caxton Hall, Westminster, *on January 28th to consider the general* question of better conditions for nurses. Delegates were present from about sixty organizations, including the General Nursing Council, the College of Nursing, the British Red Cross Society, the Professional Union of Trained Nurses, Queen Victoria's Jubilee Institute, and the Royal British Nurses' Association, also the nursing staffs of the principal London and some of the provincial hospitals. The British Medical Association was represented by Sir Jenner Verrall, Mr. H. S. Souttar, Dr. G. F. Buchan, and the Deputy Medical Secretary, Dr. G. C. *Anderson. The Society of Medical Officers of Health* and the Medical Women's Federation were also represented. The other organizations were philanthropic bodies concerned with social services and unions of hospital and other workers.

A draft report on the nursing profession was placed before the conference. It had been prepared by the Standing Joint Committee of Industrial Women's Organizations —embracing some twenty-seven different bodies—and the Labour Party's Advisory Committee on Public Health. In this document it was stated that the nursing profession was relatively worse off with regard to remuneration, hours, and general conditions of labour, despite the technical training which *nurses had undergone, than any* similar group of workers. Instances were quoted where nurses were required to work a 66-hour week on day duty and an 84-hour week on night duty, and the 12-hour night duty was described as being still an all too frequent occurrence. The report suggested that the training school organization should be separated from the organization of the hospital, and that a probationer should be looked upon as a student, not as a source of cheap labour for the hospital authorities. The greater part of such work as cleaning the wards should be given over to maids and orderlies, so that the probationer's time might be devoted to the study and practice of her profession. It was also recommended that the training school as an educational institution should receive grants from the educational authorities. A 48-hour standard week, with an 8-hour day, inclusive of lecture hours, was advocated, and it was stipulated that no *untrained nurse should have full* responsibility for a ward either day or night, that proper nurses' homes should be provided, that not less than one full day a week and one week-end a month should be allowed off duty, that the annual holiday should be not less than three weeks, and that the minimum salary during training should be £40 a year. The need of a trade union for nurses was also urged in the report, which described it as unfortunate that, owing to the tradition of the profession, the average nurse should regard a trade union as a body of manual workers continually taking part in strikes. The nurse did not realize that every profession had found organization necessary. Doctors and lawyers had formed their own professional associations, and civil servants and teachers had their trade unions. An organization of working nurses could speak effectively for the members of their calling, and with such a body in being it would be practicable to secure a national joint council representing on the one hand all the nursing services, and on the other the State, municipal, and other employers. Such a body would be able to work out a satisfactory superannuation scheme, to lay down maximum working hours and minimum standards of remuneration, and to deal with working conditions generally.

The Labour Party and Public Health.

The conference was opened by the Right Hon. J. RAMSAY MACDONALD, M.P., the leader of the Labour party. He expressed the view that the nursing profession was on the eve of revolutionary change. He begged the ladies before him not to be frightened by the word "revolutionary," which meant nothing bloody at all, but merely the ferment of ideas—the pot, so to speak, coming to the boil. He could remember perfectly well, when he was a happy patient in a large London hospital, discussing with the kindly lady who looked after his well-being this question of the nursing profession. She was most charming in her simplicity and directness. She thought of the nursing profession as something like a companionship of acolytes attending in the courts of a great temple. No doubt her idealism still remained, and he hoped it always would, but he doubted whether many nurses would express their ideas of their function in quite that form to-day. Changing conditions, economic and other, had to be faced. He dwelt upon the great necessity of improving the nurse's status, avowing himself a tremendous believer in status. "I would work for sixpence an hour if I felt that my status was good rather than for half a crown an hour, at the same job, if I felt that I was regarded merely as a hewer of wood and a drawer of water." They were apt to lose sight of the fact, said Mr. MacDonald, that while pay must, of course, be sufficient to meet the requirements of life, it was not possible by payment in pounds, shillings, and pence to draw forth the best effort of men and women. The true coinage was dignity, respect, and an admission to a common fellowship. The Labour party, he added, was not concerned only with factories and workshops; it took cognizance of all forms of social service, was just as much interested in the medical and nursing professions as in coal mining, and the public service of health was one of the essential things included in its conspectus. He said also that the Labour party did not forget to pay its homage to the past; it looked behind as well as before, had gratitude as well as hope, and was sensible of the roots as well as of the uprising growth.

Dr. SOMERVILLE HASTINGS, who opened the discussion, said that it might be asked why the Labour party, uninvited by any large or representative body of nurses, had thought fit to interest itself in the nursing profession. The experience of history showed, however, that if they waited until those in need of advice or help asked for it they might have to wait for a very long time. There were many indications that all was not well with the nursing profession. The report of the Select Committee on the General Nursing Council, published in 1925, stated that complaints were made by several witnesses of the difficulty of recruitment of nurses generally, not only in regard to the number but also the quality of the applicants. It was impossible for any party that concerned itself with matters of public health to fail to appreciate the importance to the country of an adequate supply of properly trained and efficient nurses. The two points to which they had specially addressed themselves were the need for efficient preliminary education and the dangers of exploitation of the nurses during and after training. A high standard of preliminary education was recommended because nursing must always be a highly skilled profession. The Select Committee just mentioned drew attention to the fact that many probationers had no education beyond the elementary stages, and cited this as a possible cause of the high percentage of failures to pass the State examination. That things were not much better in the United States was shown by the statement of the dean of the Yale School of Nursing, that out of a total enrolment of 15,898 nursing students, only 115 were college graduates, while 66 had had a partial college education. Those who had prepared the present report had also been impressed by the necessity for sufficient time being allowed for rest and study during training. The period of training for the nurse was often accompanied by considerable mental as well as physical strain.

Mr. G. P. BLIZARD, secretary of the Labour Party's Advisory Committee on Public Health, said that the present conference on nursing rounded off and completed the Labour party's survey of the health services of the community. That survey had started with the preventive and curative medical services, this had been followed by an inquiry two years ago into the hospital situation, and this again by the present survey of nursing. Having completed this survey of the health services of the community,

it was intended to proceed to consider the "consumer's" side of the question, and to deal during the next year or two with the health of the people from the cradle—or before the cradle, because it would embrace pre-natal services—to the grave. The Labour party had been much flattered on starting its first survey to find that the Government had set up a Consultative Council at the Ministry of Health, presided over by Lord Dawson of Penn, which followed very closely a large number of the recommendations of their (the Labour party's) original report. It was promised that special committees of inquiry should be formed to consider the nursing and midwifery services of the country, but on writing to the Ministry of Health a fortnight ago to ask if those promises had been implemented, he was informed that neither of these committees had been brought into being. Mr. Blizard estimated the number of nurses at 50,000, and mentioned that only 3,000 or 4,000 had any provision with regard to pensions.

Nurses and Trade Unionism.

The most lively, if not the most fruitful, discussion related to the question of a trade union for nurses. Mr. E. B. TURNER, F.R.C.S. (Central Council for Nursing in London), speaking as one whose professional experience of nurses went back to the days when Sairey Gamp was scarcely cold in her grave, said that as an individualist there were some things in the report with which he could not agree. He would regret to see nurses organized in a trade union if this involved doing everything that trade unions did at the present time. He would rather see them in some organization on the lines of the British Medical Association, which was not, and by its Articles could not be, a trade union, and yet exercised the very greatest influence and power. In that way nurses could make full use of collective bargaining. Mr. Turner's statement that the British Medical Association was not a trade union was received with loud ironical laughter by the trade union section of the conference.

Miss COX-DAVIES (College of Nursing) said that the recommendation in the report that the nurses should organize as the medical and legal professions had done had been already followed. True, the College of Nursing had not organized itself on trade union lines, because it did not think those lines best suited to the nursing profession. There was a nurses' trade union, the Professional Union of Trained Nurses, which, she believed, had a membership of about 400. But the College of Nursing had already secured great advantages for the profession. Mrs. BEDFORD FENWICK (British College of Nurses) said that what the profession needed was self-government and self-determination. She criticized the General Nursing Council as a very futile body, largely constituted of those who were not in sympathy with the rank and file of the profession.

Mrs. SIDNEY WEBB, who gave an interesting sketch of the powerful corporation of midwives (women) which flourished in the sixteenth and seventeenth centuries, made some of her audience restive by her criticism of one sentence in the Labour report—namely, "The only way in which nurses can deal effectively with their conditions and exercise any sort of equality in bargaining power is for the profession to be organized on trade union lines." She suggested that the word "vocational" be substituted for "trade union"; it was quite as definite a term, and she thought that nurses might well have regard to the example of the British Medical Association and the National Union of Teachers and study their reasons for dispensing with the term "trade union." Mr. Turner's challenge was taken up by Mr. GEORGE GIBSON (National Asylum Workers' Union), who commented upon the "careful distinction between the functions of the British Medical Association and the unconstitutional activities of the plebeian trade unions." When medical men, said Mr. Gibson, reached a point at which they could prevent one another from applying for a post when the salary was unsatisfactory, they had not much to learn from trade unionists. There did not seem to him to be much distinction between the withdrawal of labour because the salary was insufficient and the non-commencement of labour for a similar reason. It was not necessary for a trade union to have a strike clause; any body of persons organized on a purely vocational basis was a trade union. Mr. Gibson also made the suggestion that when the next valuation of approved societies took place some of the surplus, which would still remain in spite of the "raids," should be allocated to the provision of a panel nursing service. The nursing profession, he said, had suffered from too much patronage, even though the people who had patronized it had done so with the best intentions.

Sir JENNER VERRALL (British Medical Association) said that no one, certainly no medical man, would deny that the conditions in the nursing service were capable of improvement, but he thought that nurses should consider carefully the character of the organization they set up for bringing about improvement. After all, the success of the nursing profession would depend a good deal on how far they could persuade the medical profession, which was one of their big "consumers," that nursing efficiency was promoted, and not merely the advantages of the nurse. It was a question whether a trade union organization would assist them in that respect. Mrs. PAUL (Professional Union of Trained Nurses) said that Sir Jenner Verrall seemed to infer that the type of nurse would depend upon the character of her professional organization; it depended much more on the school where she got her training.

The discussion closed with an appeal from Dr. Marion PHILLIPS, chief woman organizer of the Labour party, and Mr. S. P. VIANT, M.P., that the various nursing organizations should follow the plan already adopted in other ranks of industry, and consent to a process of elimination, so that there might be one strong and representative body.

Conditions in the Nursing Profession.

No resolutions were taken in the course of the conference, but it was stated that all the suggestions would be carefully considered by the conveners. Lord COZENS-HARDY (National Association of Insurance Committees) confessed to disappointment at the report because it did not direct attention to the broad question of the adequacy of the nursing service, but concerned itself with the terms and conditions of employment. He also objected to a recommendation that district nursing would be better run by local authorities. Dr. A. SALTER, M.P., said that district nursing as at present organized, devoted as the nurses were, was inadequate to meet the situation in the poorer districts. Degrading methods had to be resorted to to obtain the necessary funds, such as grotesque street processions and gambles. District nursing ought to be transferred from voluntary organization to the support and control of the public authorities, and thereby a public recognition of collective responsibility for the sick would be secured. He commented upon the lack of massage services in or near the homes of the people. Mr. F. HUGHES (National Union of Clerks) said that the inadequacy of the present nursing service was largely due to bad conditions, and the position would be much worse if a number of women did not feel a definite vocation for nursing, for which they were prepared to make sacrifices; and Dr. A. H. BYGOTT declared that the inadequacy of the nursing service was so completely taken for granted by the compilers that they left it out of the report.

In the course of further discussion Miss COWLIN (General Nursing Council) asked how many so-called training schools for nurses had a separate appropriation in the hospital budget. Miss M. E. SPARSHOTT (matron, Manchester Royal Infirmary) considered that 21 was the minimum age for nurses in a general hospital. At 18 a girl might be employed in the smaller or special hospitals, but for a general hospital, where accident cases of a bad kind were continually coming in, she was immature under 21. Miss Sparshott rather deprecated the 48-hour week, which made it appear as if the nurse's duty could be, so to speak, shut off. A 56-hour week worked out better. Patients objected to a too frequent change of nurse. As to salaries, it must be borne in mind that during the probationary period the girl was receiving professional training; fathers must learn to help their daughters in their professional education as well as their sons. She demurred to the suggestion that there was no effective organization in the nursing profession. After all, it was

an organized body of nurses who got State registration through. Dr. VERE PEARSON said that now that registration had secured a certain minimum standard, it should be possible to bring about more grading above that standard, so that all nurses were not forced into one mould.

Miss A. SAYLE (*Women Sanitary Inspectors and Health Visitors' Association*) spoke on public health and preventive services, and mentioned that among 1,074 health visitors a recent inquiry discovered that there were twenty-two different kinds of certificates and qualifications, and that these were held in eighty-eight different combinations. She also mentioned that 300 local authorities gave ninety-one minimum salaries, varying from £120 to £244, the average, including London, being £172, and excluding London £166. Dr. STELLA CHURCHILL looked forward to the day when the health visitor would be a fully trained nurse and midwife, so that the family instead of the individual might be considered the unit, and working-class homes would be spared the embarrassment of having several different people call to look after the health of members of the same family.

In closing the proceedings, Dr. SOMERVILLE HASTINGS expressed the hope that after this faithful dealing the profession of nursing would be better able to work out its own salvation.

OBSTRUCTION OF ULTRA-VIOLET RADIATION BY AIR IMPURITIES.

HE report of the Advisory Committee of the Meteorogical Office on Atmospheric Pollution for the year ending larch, 1926, includes an attempt to correlate the obstruction of ultra-violet radiation as measured by the acetone lue method with the quantity of suspended impurity in he air. For this purpose the intensities of ultra-violet adiation from the sun as measured at Kingsway (London) nd Greenwich have been compared with the suspended mpurity as measured at Westminster.

To eliminate the effect of cloud as far as possible a selecion was first made of all days during which the sky was ot more than one-quarter covered with cloud. During hese days the average amount of suspended impurity as neasured by the Owen automatic recorder, between sunise and sunset, was plotted with the ultra-violet radiation eceived. As there is no means of getting wholly rid of the ffect of cloud, the close relation brought out, while quite vident, cannot be expected to follow any definite law. The records taken by the acetone blue method in various moky towns and clean places show that the former do not eceive a third of the ultra-violet radiation which reaches he latter.

Dr. Leonard Hill informs us that these records have now been made for over two years by the Department of Applied Physiology of the National Institute for Medical Research, with the help of voluntary observers in various smoky and clean places. The acetone blue solution, the use of which was first suggested by Mr. A. Webster, absorbs ultra-violet rays of shorter wave-length than about 3,300 Angström units, and are thus, Dr. Hill states, very suitable for measuring the biologically active ultra-violet rays of the sun and sky shine. The cutting out of these rays is, in his opinion, one of the worst results of smoke pollution, leading as it does to ill health, both by want of direct action of the rays on the skin, and by indirect action through impoverishment of green food, and so of milk and butter. The antirachitic vitamin is produced by ultra-violet radiation.

Dr. Owen's ingenious automatic filter and jet and dust-counters have advanced the study of smoke pollution very greatly. Relations between dust content of the atmosphere and wind, and between dustiness and visibility, have been established. The product of the number of dust particles per cubic centimetre, the relative humidity, and the visibility in miles have been found to be constant. At Paris it had been found that six miles from the fortifications there is a loss of 21 per cent. of light when the wind blows from the city. Dr. Owen has shown that smoke drifts for miles, and reaches places far from the smoky cities.

One of the most interesting of his observations is on the relation between hygroscopic salts in the air and haze. Owing to deliquescence fog may result at humidities much below the saturation point. Sea fogs are thus produced by the salt sprayed into the air. The salt does not travel far from the sea under any conditions, for owing to the rise of relative humidity at night and the consequent deliquescence of the salt the particles fall down through increase in weight. The breathing of traces of sea salt is probably an important part of the beneficial action of sea air. The salt particles may excite exudations of lymph in the pulmonary alveoli and thus have a cleansing action. Traces of iodine may be secured by breathing sea air as well as by swallowing salt water when bathing. Rain and snow are great cleansers, and in winter afford relief to the pollution of the atmosphere that goes on in cities.

Dr. Hill adds that during a recent visit to the Institute of Professor Storm van Leeuwen at Leyden he found the city air being cleaned by means of refrigeration; after warming it suitably it is passed through dust-free sleeping chambers. Many cases of asthma and chronic bronchitis are greatly relieved by occupying these chambers by night and are thus enabled to pursue their business occupations by day. Evidence has been obtained at Leyden that these patients are sensitive to certain constituents of the dust in the air, such as moulds, and that irritation of the respiratory membrane starts therefrom. He is inclined to believe that even cases of pulmonary tuberculosis may start from such sensitivity and be relieved in the first stage by a dust-free atmosphere. The Alps, Dr. Hill points out, afford both dust-free air and abundance of light. The purification of the air, he concludes, is far the most important problem of hygiene of to-day. Through this, and by education of people in the matter of a properly balanced diet and adequate ventilation and exercise, we may hope to reduce catarrhal infections.

Nova et Vetera.

A MEMORABLE OBSTETRIC TRAGEDY.

THE recent sale of objects from Claremont House, Esher, may make it opportune to recall the tragedy which occurred there in 1817—the death, immediately after her confinement, of the Princess Charlotte of Wales, only child of the Prince Regent and wife of Prince Leopold of Saxe-Coburg, afterwards King of the Belgians. The affair aroused a torrent of criticism at the time and has provoked comment on several occasions since. What seems to be an authoritative account of the incident was published in the *London Medical Repository* of December, 1817. The same narrative, with some changes, was published separately, as an "authentic statement," with additional observations by A. T. Thomson. As the birth of an heir to the throne of England might have been the result, it is not surprising that much curiosity was awakened when it became known that the Princess Charlotte was pregnant. Contrary to the wishes of the Court that she should be confined at Kensington Palace, the Princess decided to stay at Claremont, whither she had recently gone to reside with her husband. She had selected as her attendant Sir Richard Croft, at that time the fashionable accoucheur in London, a baronet by right of succession, not created as the reward of professional merit. It does not appear that Croft had obtained any medical degree or diploma—there was no *Medical Register in those days—but there is little doubt* that he was adequately trained according to the standards of his day, and that his recognized skill, combined with his somewhat uncommon social position, had placed him in the forefront of his branch of practice. With Croft, at the Princess's own wish, was associated Dr. Matthew Baillie, one of the leading physicians in London and, incidentally, Croft's brother-in-law. Croft resided at Claremont for three weeks before the onset of labour.

The Princess had been bled frequently as an essential part of the ante-natal routine of that time, but was in excellent spirits when labour commenced at 7 p.m. on Monday, November 3rd. From the first the pains were very weak and ineffective: the membranes ruptured early,

and this, as usual, did not help matters. At the end of twenty-six hours, progress still being very slow, Croft began to feel anxious, and sent for Dr. John Sims, another specialist in midwifery of high standing. Sims arrived at Claremont at 2 a.m. on November 5th, but did not see the patient at once, as both he and Baillie thought that his appearance might unduly alarm her. After a consultation with Croft he advised against any interference with the natural process of labour.

At *noon* the attendants first began to suspect that the baby might be dead, but still they decided against using forceps. The Princess was finally delivered of a stillborn male child at 9 p.m. It was almost immediately recognized that there was an hour-glass contraction of the uterus, and at 9.30 p.m., after a small haemorrhage had occurred, manual separation and extraction of the placenta was performed without difficulty and with practically no further loss. At this stage all of the attendants were satisfied with the patient's condition, so that at 11 p.m. Baillie went to bed, Sims lay down still fully dressed, while Croft remained on watch in the Princess's bedroom. Shortly after midnight the patient began to get very restless and vomited, though the pulse remained firm and under a hundred. At half-past twelve her respirations became embarrassed, and in spite of the three doctors' urgent efforts with every kind of cordial, she died at 2.30 a.m., five and a half hours after delivery.

The death was announced in an Extraordinary Issue of the *London Gazette* the same day, and, if contemporary records are to be trusted, caused consternation throughout the length and breadth of the realm. Even thus early it can be conjectured that slanderous tongues were busy against the medical attendants, for a *post-mortem* examination was ordered by the King. This took place on November 7th, the body being opened by Sir Everard Home, assisted by Sir David Dundas, Mr. Brande, and the apothecary of Prince Leopold's household. The report which was published in the *Repository* claims to be "a pretty accurate statement of the appearances these gentlemen observed." It was as follows:

"The membranes of the brain presented their natural aspect. The vessels of the pia mater were less distended with blood than was to be expected after so severe a labour. The ventricles of the brain contained very little fluid. The plexus choroides was of a pale colour, and the substance of the brain had its natural texture. The pericardium contained two ounces of red-coloured fluid. The heart itself and the lungs were in a natural state. The stomach contained nearly three pints of liquid. The colon was distended with air. The kidneys and other abdominal viscera were in a natural state. The uterus contained a *considerable* quantity of blood, and extended as high up in the abdomen as the navel; and the hour-glass contraction was still very apparent."

Baillie afterwards stated that the amount of coagulated blood found in the uterus was about one pint.

The examiners reported to the Sovereign that no blame could attach to the doctors in charge of the case and that everything possible had been done in the way of treatment.

The editors of the *Repository* expressed considerable uncertainty as to the exact cause of death, and we presume that contemporary professional opinion was correspondingly vague. It has been held by some, in the light of later knowledge, that pulmonary embolism must have occurred, a condition not recognized at that time or till many years later, but there is no direct evidence of this, whereas there is no doubt that a concealed post-partum haemorrhage took place, and this, occurring in an already exhausted patient, may be accepted as quite sufficient to account for the death.

In spite of the public vindication of Sir Richard Croft's care and skill—and let us remember in this connexion that we of the present day have no right to be severe in our judgement of the treatment adopted one hundred and nine years ago—a campaign of vilification was continued against him, and must have adversely affected his practice. This, added to the natural concern of a man of sensitive disposition at being the victim of such unfortunate circumstances, so preyed upon his mind that he shot himself at Miss Cotton's Nursing Home in Wimpole Street on February 13th, 1818, while awaiting the delivery of the wife of the Head of a College, whom he had been summoned to attend.

THE LISTER CENTENARY IN LONDON.

A COMMITTEE consisting of representatives of the Royal Society, the Royal Colleges of Physicians and Surgeons, the Royal Society of Medicine, the British Medical Association, the universities and other institutions interested, has been formed to organize a celebration in London of the centenary of the birth of Lord Lister, which falls on April 5th next. Representatives of learned societies, universities, and medical bodies in Great Britain, and delegates from the Dominions and principal foreign countries, will be present. The delegates will be received by H.M. the King at Buckingham Palace on Monday, April 4th. The programme so far arranged is as follows:

April 5th.

Reception and short addresses by some of the delegates in the Great Hall of the British Medical Association.
Conversazione at the Royal College of Surgeons of England.
Dinner given by the Merchant Taylors Company, of which Lord Lister was a member.

April 6th.

Memorial Service in Westminster Abbey: Address by the Bishop of Birmingham.
Discourses in the Robert Barnes Hall of the Royal Society of Medicine on Lister as Physiologist, Pathologist, and Surgeon, by Sir Charles Sherrington, Professor W. Bulloch, and Sir Berkeley Moynihan.
Conversazione at the rooms of the Royal Society.

The Executive Committee is constituted as follows:

Sir JOHN ROSE BRADFORD (President, Royal College of Physicians), *Chairman*.
Sir JAMES BERRY (President, Royal Society of Medicine).
Sir JOHN BLAND-SUTTON, Bt. (lately President, Royal College of Surgeons).
Professor WILLIAM BULLOCH, London Hospital.
Sir WATSON CHEYNE, Bt.
Dr. H. H. DALE (a Secretary of the Royal Society).
Mr. R. G. HOGARTH (President, British Medical Association).
Sir BERKELEY MOYNIHAN, Bt. (President, Royal College of Surgeons).
Sir HUMPHRY ROLLESTON, Bt. (lately President, Royal College of Physicians).
Sir ERNEST RUTHERFORD (President of the Royal Society).
Sir CHARLES SHERRINGTON (lately President of the Royal Society).
Sir HAROLD STILES (lately President, Royal College of Surgeons, Edinburgh).
Sir STCLAIR THOMSON (lately President, Royal Society of Medicine).
Mr. W. TROTTER, University College Hospital.
Mr. LOGAN TURNER (President, Royal College of Surgeons, Edinburgh).
Professor A. YOUNG (representing the University of Glasgow).

England and Wales.

THE LATE DR. STRANGEWAYS.

A MEMORIAL service for the late T. S. P. Strangeways, M.A.(Hon.), M.R.C.S., Huddersfield Lecturer in special pathology and director of the Cambridge Research Hospital, who died on December 23rd last, was held in the Chapel of St. John's College, of which he was a member, on the afternoon of Tuesday, January 25th. The anthem, Tennyson's "Crossing the Bar," and Faber's hymn, "Hark! Hark, my Soul!" were sung by the College choir, and the Master of St. John's (Sir Robert Scott) was present and read the lesson. An obituary notice of Dr. Strangeways was published on January 8th (p. 82), and a meeting has been held this week in London at the Royal Society of Medicine to inaugurate a Strangeways Memorial Fund, the main purpose of which, as stated in our last issue at page 206, is to complete the education of his sons.

BERRINGTON HOSPITAL, SHROPSHIRE.

The former workhouse of the Atcham Board of Guardians, which has been remodelled and equipped as a hospital, was opened by Lady Berwick on January 27th. The building was originally erected in 1792, and during the war was converted into a military hospital unit with about 500 beds. The cost of the new fittings has been met by the payment made by the War Office in respect of dilapidations. The wards have been enlarged, and there is at present accom-

modation for 140 beds, with provision for an increase up to 300 if required. A new electric light plant has been installed, and apparatus for radiant heat treatment. A spacious and well equipped operating theatre has been constructed, and nurses' quarters and an administrative block have been secured by the conversion of some old rooms. Beds are available for private as well as for Poor Law patients, and the suggestion has been made that in the future a maternity home may be established in the building.

DR. JAMIESON HURRY AND READING.

Dr. Jamieson Hurry has added another to his numerous gifts to Reading by providing a valuable collection of specimens illustrating economic botany, which have now been arranged in a special room at the Reading museum. Many of the plants were cultivated by Dr. Hurry in his garden, and he also obtained examples of foreign species. The collection was housed in his private residence until he removed to Bournemouth last year, after having spent forty years in Reading. A descriptive catalogue of the exhibits has been prepared, and this new museum of economic botany will provide facilities for giving instruction in the ways in which plants minister to human welfare. In opening the museum on January 25th, Dr. Hurry described how the collection had grown during the last twenty years, his purpose being to arrange for illustrations of the growing plants and the commercial products derived from them to be exhibited side by side for study. He hoped that in the future it might be possible to establish a small educational garden and conservatory to complete the scheme. Dr. Hurry's previous gifts to Reading include ten historical pictures dealing principally with Reading Abbey.

CORONERS' INQUESTS IN THE CITY OF LONDON AND SOUTHWARK.

During 1926 the total number of coroners' inquests in Dr. Waldo's districts of the City of London, Southwark, and Holloway Prison amounted to 519, necropsies being performed in all but 16. The inquiries included 25 cases of suicide, 158 of accidental death, and 94 of death due to natural causes; of the suicides 15 were men and 10 women. The cost of the inquests in the City was £463 and in Southwark £435. The number of fatalities caused by vehicular traffic was greater than in any previous year. In order to prevent traffic accidents Dr. Waldo secured the adoption by the Southwark Borough Council and police force in 1921 of fixed road crossings, and the idea has since been partly put into practice in Westminster. The number of deaths due to, or accelerated by, the administration of anaesthetics also rose, and Dr. Waldo repeats his recommendation that further research should be undertaken. The Coroners (Amendment) Act, 1926, which received the Royal assent at the end of the last session of Parliament, entitles medical practitioners attached to hospitals and other institutions to receive the increased statutory fee for making necropsies, and giving evidence in coroners' courts, on and after May 1st. Dr. Waldo for many years has strenuously advocated this reform.

Scotland.

INFLUENZA IN SCOTLAND.

THE Scottish Board of Health has addressed to the medical officers of health of the sixteen principal towns of Scotland and to county medical officers of health a communication asking for returns in regard to influenza. Information is desired respecting the clinical character of the disease, if present, and the general measures taken to cope with it, particularly those of international interest. Information is asked from school medical officers as to the number of children absent from school on account of influenza, from hospitals as to the number of cases admitted, and from clinics, health visitors, and general practitioners as to the number of cases being treated, as well as from factories as to the number of absentees from work on this account. The type of case encountered so far in Scotland has been generally mild, and both the catarrhal and non-catarrhal varieties have occurred.

GIFFORD LECTURES IN GLASGOW.

Dr. J. S. Haldane, LL.D., F.R.S., has begun the delivery, in the University of Glasgow, of a course of ten Gifford Lectures on "The sciences and philosophy." He began by comparing the general principles forced upon us in the isolated subjects of the physical sciences and biology. In physics and chemistry reality as it appeared in inorganic phenomena was studied. The biological sciences, on the other hand, dealt with distinctive phenomena presented by living organisms, such as conscious activity. Regarding life from a strictly physical standpoint, it had to be admitted that living structure was only an appearance like that of a flowing stream, and we were obliged to assume that the flow was one of molecules, atoms, and electrons into various combinations with one another and producing a constant flow and transformation of energy. We lived at present in an age of popular credulity as great as that of the Middle Ages, but of all the forms of popular credulity, the lecturer said that he knew none more gross than the widely spread popular belief that in the physical and chemical structure of the living organism lay the explanation of its specific behaviour. With the advance of knowledge, however, it had become increasingly apparent that those who held a purely physico-chemical conception of visible nature must have recourse to a theory of constant supernatural intervention to help out the defects of their physico-chemical theory of life. Any theory implying so-called supernatural intervention was repugnant to science, since it implied the giving up of the attempt to discover consistency and order in nature. The lecturer also proposed to maintain in later lectures that any such theory was inconsistent with religion. Descartes, the lecturer said, had in the seventeenth century attempted to reach forward towards a complete mechanistic or physico-chemical conception of the phenomena of life, and had endeavoured to show that the living body itself was produced from its material elements by mechanical processes. The weakest feature in the Cartesian physiology had been embryology. Even if this had been based upon any definite observations it could have given no account of the original formation of such an organ as the heart. It had been generally supposed that on the publication in 1859 of Darwin's *Origin of Species* a mechanistic explanation of the origin of structure had been discovered. In the lecturer's view, however, the fact of evolution took them no nearer to the answer to the question, however strongly they might be convinced that evolution was a natural process. Darwin had made a final end of the science or theology which treated creation as an act by which a vast amount of structural machinery was at one stroke brought into being and then left to act. He did not, however, put in its place any mechanical theory of how an organism maintained and transmitted its specific structure from generation to generation. The real assumption behind the mechanistic physiology of the last century was that the whole visible world of nature could be interpreted as a physico-chemical system in the sense of Newton's interpretation of the inorganic world. The essential question for the biologist was whether this assumption would fit the data of his observations. Various facts had been brought to light by the writings and experiments of Claude Bernard, for example, in connexion with the physiology of respiration, which might be regarded as nothing but a mechanical process—but there was no real prospect of a complete systematic treatment of biology on these lines as a part of physics and chemistry. The structure of animals was reproduced from generation to generation, and of this reproduction the mechanistic theory could give no account. The widest stretch of imagination could not conceive of structural machinery which went on reproducing itself indefinitely, and the more complicated the structure and chemistry discovered in an organism the more hopeless did the mechanistic explanation become. It was often said that scientific physiology was progressively revealing the mechanism of life, but what in reality it was revealing was the detail of co-ordinated activity. Descartes's formulation

of a mechanistic theory of life had led immediately to the pronouncement of a vitalistic theory by Stahl, who maintained that bodily processes were guided, both consciously and unconsciously, by the soul, the presence of this guidance distinguishing living from non-living bodies. Vitalism had almost disappeared during the development of the mechanistic movement in the middle of the last century. The real strength of vitalism now, as in the seventeenth century, was that it recognized the co-ordination which could be traced in the activities of all living organisms. Actual experience showed that there was no end to the further light which experimental investigation might throw on physiological phenomena. Vitalism was thus an unsatisfactory hypothesis from the standpoint of scientific advance. Accordingly, the mechanistic conception of life was still reckoned orthodox by many physiologists and biologists.

PROPOSED DAIRY INSTITUTE AT ABERDEEN.

At a luncheon given recently by the governing body of the Rowett Research Institute at Aberdeen, Sir John Gilmour, Secretary of State for Scotland, recalled the generosity of the late Dr. J. Q. Rowett, who had shown great interest in scientific research on agricultural problems. One of the great needs of the present time was a dairy research institute in Scotland. More than 50 per cent. of the milk and milk products used were imported, and in certain months of the year the home farmer had great difficulty in disposing of his surplus milk. Sir John Gilmour expressed the hope that the new research institute which it was proposed to establish in the south-west of Scotland under the auspices of the University of Glasgow and the West of Scotland Agricultural College would receive whole-hearted support, and that it would become a great national scientific institution, capable of dealing with both agricultural and medical problems regarding the consumption of milk and milk products. In a presidential address delivered last week to the Scottish Metropolitan Division of the National Veterinary Medical Association of Great Britain and Ireland, Professor R. G. Linton recommended the establishment of a central laboratory wherein bacteriology and chemical testing of graded milks could be carried out instead of by the local authorities. He advocated also State financial aid under easy terms of repayment to farmers wishing to create herds free from tuberculosis, but who were prevented from doing so owing to the lack of sufficient capital to meet the initial expense of reconstructing their herds.

ORTHOPAEDICS.

The question of co-operative action for the prevention and treatment of crippling was under consideration at a meeting held lately in the City Chambers, Glasgow. Dr. A. S. M. Macgregor, medical officer of health for Glasgow, occupied the chair, and among those present were Professor Leonard Findlay of the University of Glasgow; Mr. A. MacLennan, university lecturer on surgery and orthopaedics at the Royal Hospital for Sick Children; Dr. G. H. Stevenson of the orthopaedic clinic; Dr. E. T. Roberts, medical officer to the Glasgow education authority; and representative medical officers of health and medical practitioners from the West of Scotland. Mr. MacLennan explained that at present no scheme existed for co-ordinating the orthopaedic clinic of the Royal Hospital for Sick Children with medical practitioners, local authorities, and local education authorities, and that lack of continuity thence resulted alike in observation and treatment, so that many cases which left the clinic with good prospects either lost the ground which they had gained or ceased to progress. Those present at the meeting were unanimous in the view that co-operation was required. A subcommittee was appointed to obtain all necessary information and to draft the lines of a scheme.

RECENT GIFTS TO EDINBURGH ROYAL INFIRMARY.

At a meeting of managers of the Edinburgh Royal Infirmary on January 24th it was intimated that the late Mr. John Cowan, W.S., had left to the Infirmary £40,000 on the expiry of a life rent, for the purpose of endowing a ward in memory of his father, the late Lord Cowan. The important intimation was also made that a half share of the residue of this estate had been left for the purpose of equipping or assisting to equip a ward or hospital for paying patients. The amount of this bequest is not yet ascertained, nor is it known whether it will be sufficient to carry out what is by many regarded as a most eminently desirable addition to the Royal Infirmary of Edinburgh, which at present cannot make any provision for a patient who desires to pay for his maintenance and treatment. The late Mr. Edward Clark, of the firm of Messrs. R. and R. Clark, printers, recently bequeathed to the Royal Infirmary a sum of £10,000, and a sum of £1,000 to the Royal Hospital for Sick Children, Edinburgh.

Ireland.

TYRONE DIVISION.

THE inaugural meeting of the Tyrone Division of the British Medical Association was held in Omagh on January 26th. Notwithstanding that there was a storm with heavy rain the attendance of members was very large, and many of them came from the remotest part of the county and at much personal inconvenience. Dr. Edward Thompson, D.L., was elected with acclamation chairman of the Division. This was only a fitting tribute to Dr. Thomson, who has been for over fifty years a strenuous fighter for the rights of medical practitioners. He is one of the best known and most popular medical men throughout Ireland, and in the pre-boundary days was a regular attendant at medical meetings in Dublin, where his presence was always sought for and welcomed. It will be a source of much pleasure to medical men in every part of Ireland to learn that Dr. Thompson has recently resumed his practice quite restored to his former health. Dr. William Lyle (Newtownstewart) was elected vice-chairman. Dr. Lyle has also been a well known figure in medical politics, and whenever strong action had to be taken he was always a vigorous and trustworthy leader. Dr. Bradley (Fintona) was elected secretary and treasurer, and Dr. Lynch (Omagh) assistant secretary. A representative executive committee was also elected. The Irish Medical Secretary, in response to a special invitation, was present and received a very warm reception. It was much regretted that Dr. H. P. Malcolm, Honorary Secretary of the Ulster Branch, found himself at the last moment unable to attend the meeting. The members of the Division, with the Irish Medical Secretary, on the conclusion of the business of the meeting, lunched together at the Royal Arms Hotel.

PREVENTION OF SMALL-POX.

A circular letter has been addressed by the Department of Local Government and Public Health to all local health authorities in the Irish Free State pointing out that the epidemic of small-pox prevalent in England now threatens to assume a more serious character and to develop into the older type, involving grave illness and mortality. Memories still remain of the terrible visitations of 1871 and 1878; the complications which then occurred were truly protean in character—for example, multiple abscesses; gangrene; sloughing of the eyelids; inflammatory conditions of the eyes, ears, and nose, often resulting in loss of sight and partial or complete deafness; swelling of the tongue and throat, leading to difficult swallowing, embarrassed breathing and ultimate death; inflammation of the various internal organs; acute mania; paralysis; blood poisoning; joint and bone disease. The infection of small-pox might be conveyed by patients through the medium of other persons or by articles of clothing, to which it clings. It was of vital importance that the essential precautions should be adopted to render the population generally immune from the scourge. An outbreak would prove a very serious menace to the prosperity of the food and export trade, on which the financial success of the country so largely depended. It would likewise affect the tourist traffic adversely in the coming season. Vaccination or revaccination constituted the only safeguard against attack

for persons exposed to the infection of small-pox. The Minister, therefore, requested the local authority to take all necessary steps without delay to compel the defaulters to comply with the law, and to bring to the notice of all those desiring revaccination that facilities for this purpose are at their disposal gratuitously. The immunity of the country had been largely due to the vigilant care of the sanitary authorities, more especially at the ports, and to the earnest co-operation of the medical profession. It would be most unfortunate if the country's favourable position in this matter were imperilled because of apathy or wrong-headedness.

Correspondence.

CLIFFORD ALLBUTT MEMORIAL AT PAPWORTH.

SIR,—A small committee of the friends and admirers of the late Professor Sir Clifford Allbutt has decided to erect to his memory at Papworth two cottages, with which his name will be permanently associated, for men disabled by tuberculosis. The men will be chosen from among those who could not, under ordinary conditions, support themselves and their families.

Sir Clifford as President of Papworth Colony from the beginning was always deeply interested in the work there, and it is felt that there could be for him no more fitting memorial.

A certain amount of money has already been promised, and we shall be very grateful if those who would like their names added to this memorial to a great man will kindly send donations, however small, to Mrs. Marcus Dimsdale, Papworth Hall, Cambridge.

It is hoped that the cottages will be opened some time during the summer by H.R.H. the Prince of Wales, and that as many subscribers as possible will endeavour to be present.—We are, etc.,

FREDERICK MILNER.	ROBERT JONES.

January 29th.

THE MENTAL DEFICIENCY BILL OF 1926.

SIR,—I shall be obliged if you will allow me space to reply to Sir Bryan Donkin's letter on this subject which appears in your issue of January 22nd (p. 162).

With regard to the definition of mental deficiency, I am sure that no one realizes more than does Sir Bryan the difficulty of drafting a satisfactory definition of mental defect; for he was a distinguished member of the very important Royal Commission which was responsible for the definitions of the Act of 1913, and, in spite of all the ability and knowledge brought to bear upon the subject, he admits, what is indeed common knowledge, that these definitions have occasioned considerable difficulty in administration and that their revision is necessary.

The purpose of a definition is, of course, to define the class to whom it is intended to apply and to exclude those to whom it is not intended to apply. The problem which first confronts us is, therefore, Who are the mentally defective? Speaking literally, both lunacy and dementia may be termed states of mental defect, but for many years this latter term has been used in a much more specific sense, and mental defect is now restricted to a state of incomplete mental development of such degree that the individual is incapable of managing himself or his affairs, or is in need of some degree of care, supervision, and control. It is now generally recognized that mind attains a degree of development which is adequate for the maintenance of independent existence by about the age of 18 years. It follows that interference with development before this age will produce varying degrees of mental inadequacy or defect, but that after this age it will not do so. Such interference may be of two kinds: (1) there may be an inherent defect of developmental potentiality or "urge"; and, dependent upon the degree of this, mental development will come to an end at various stages of incompleteness; (2) development may be brought to a standstill by the operation of some external agency—for example, injury or disease of the brain.

The difficulty which has been experienced in the administration of the Act is due to the failure of the existing definitions to make these points clear. Although the words "from birth or from an early age" were intended to differentiate the incompletely developed mind from the mind which, subsequent to adequate development, is *in process* of disorder or decay, they have often been interpreted so narrowly as to exclude persons undoubtedly defective, but in whom the defect did not manifest itself within the first few years of life. In actual practice, also, they have often been interpreted as meaning that the defect must be due to inherent causes, and hence many magistrates have refused to recognize an arrest of development brought about by injury or disease (especially if occurring after the first decade) as coming within the terms of the definition.

The problem is to devise a form of words which will include every case of defective development of mind, however produced, which is of such a degree as to necessitate care, supervision, and control—and which will exclude any other forms of mental abnormality. After careful consideration I am of the opinion that the definition contained in the bill now withdrawn does this. It says that mental defectiveness "means a condition of arrested or incomplete development of mind," and that this may be either "innate or induced after birth by disease, injury, or other cause." Sir Bryan Donkin considers this definition too vague and too comprehensive, but he suggests a form of words which is far more so, and which not only fails to include any reference to the operation of external causes, but which would include all cases arising up to the attainment of complete adolescence. If the vague term "complete adolescence" has any definite limit at all, I believe this is generally considered to be somewhere *between the twenty-first and the twenty-fifth years.*

Sir Bryan Donkin strongly objects to the words "or other cause," apparently on the grounds that the "cases of those with arrested development are indicated apart from those affected by 'other causes'." This is a complete misconception. The bill says clearly "arrested development . . . induced by disease, injury, or other cause," and does not deal with any cases other than those of incomplete or arrested mental development. Personally, I think the words "other cause" not perhaps necessary, since it seems to me likely that in practice all cases would be comprehended by the words "injury or disease." But Sir Bryan himself states that "sound scientific research is revealing more and more clearly the dependence of mental disorders generally on discoverable physical causes, and thus the practical knowledge of such causes must increase"; this would seem to afford some justification for the use of the words "or other cause."

In spite of the fact that the definition suggested by Sir Bryan Donkin would certainly include adults, he is nevertheless very anxious that this should not be done, and he appears to be greatly concerned because he thinks the definition in the bill does so. I have already explained why, in my opinion, this definition does not apply to any mental change arising after maturity, so that it seems necessary to attempt to discover the reason for Sir Bryan's definite statement to the contrary. He bases it upon the following words in Clause 5 (*b*):

> "If the place in which he is being so detained under the order of the court is not a prison or such a place of detention as aforesaid he shall be removed therefrom to a prison, or, if he is child or young person, to a place of detention."

Now this is really rather extraordinary of Sir Bryan, for the words relied upon have obviously no reference whatever to the age when the defect arose, but refer to the age of the person at the time he is being dealt with, which is a totally different thing. Since mental deficiency does not necessarily entail death at the age of maturity, there will clearly be many adults requiring to be dealt with; but by the definition of the bill this can only be done if the defect was produced before adult age was reached.

Sir Bryan Donkin expresses the hope that the term "moral imbecile" might be replaced by a more suitable

one, or perchance be abolished. Although I think that every moral imbecile is certifiable as feeble-minded, nevertheless in actual practice there are difficulties in doing this, so that the retention of this class serves a useful purpose. I entirely agree with Sir Bryan that the name might be altered with advantage, but if he will again study the bill he will see that this was one of its proposals.

I regret to have written at such length, but since there is no doubt, as Sir Bryan states, that such opposition to the bill as has been expressed is mainly inspired by imperfect knowledge of facts, it seemed necessary to attempt to explain the real position. I cannot see any single proposal in the bill which would not make alike for the increased protection of mental defectives and the community; and its withdrawal has caused great regret to all those whose work gives them a practical knowledge of the operation and imperfections of the original Act.—I am, etc.,

London, W.1, Jan. 29th. A. F. TREDGOLD.

MIGRAINE.

SIR,—Having been abroad for the last three months I have only just read the interesting discussion on migraine at the joint meeting of the Sections of Neurology and Psychology and of Ophthalmology of the Annual Meeting (JOURNAL, October 30th, 1926, p. 765).

What strikes me as strange is that the two chief characteristics of the headache—its periodicity and its one-sidedness—did not receive that amount of attention which might have been expected. Sufferers from migraine know very well in what respect that headache differs from the various bilateral headaches—for instance, "browache."

From a prolonged study of hemicrania, I should say that it possessed the following characteristics: it is periodic in that it has a more or less regular rhythm; it is one-sided; it sets in early in life (certainly as early as the tenth year); it becomes less severe after middle life, the intervals of immunity becoming longer; and it usually disappears after the fiftieth year of life. Further, it is almost always associated with nausea and vomiting, the latter often giving immediate relief. The headache is preceded by general chilliness, by fits of yawning, and by polyuria, and is accompanied by flushing and throbbing of the side of the head affected. The pain itself may be excruciating, and of a kind which patients describe as that of a wedge being forced into the head at the back of the eye.

I venture to say that some of these features find no explanation in the speeches of those who took part in the discussion opened by Professor Bramwell. I can, for instance, find no serious attempt to throw light on the periodicity, the chief characteristic of typical or "idiopathic" hemicrania. For the rhythmic nature of the headache is very striking. Dr. Harry Campbell called attention to this many years ago, and in 1902, in the *Edinburgh Medical Journal*, I published a paper dealing exclusively with the periodicity of hemicrania. Most sufferers know exactly when the headache is due—on the same day of the week, once a month, once every six weeks, or once every three months, as the case may be. I submit that until we have explained the periodicity of hemicrania we have not got at its real nature.

For the sake of having something definite to go upon, I venture to suggest the following explanation. Let it be granted that a toxaemia is the underlying condition (of which personally I have not the slightest doubt), and that the liver is the great organ of detoxication. The liver is constantly destroying poisons more or less perfectly in different persons; in some it detoxicates so perfectly that the poison never accumulates, and they therefore never have headache. In certain less fortunate persons the liver traps the poison less perfectly, so that some is always escaping over into the circulation. When the toxin accumulates beyond a certain concentration in the blood the syndrome of hemicrania is established. The exact period of this toxic saturation may be one of seven days, or fourteen or thirty or forty-two, giving the weekly, fortnightly, monthly, or six-weekly headache, as the case may be. In other words, the rhythm of the headache is dependent upon a pre-existing rhythm in the detoxicating capabilities of the liver.

The next thing that needs explanation is the one-sidedness of the headache.

Professor Bramwell does, indeed, ask, "Why should it be so often unilateral?" but no answer is forthcoming. Explanations based on disturbances of mesial organs such as the pituitary seem to me unlikely to be helpful. This periodic headache is typically unilateral, and we have to explain why this is so.

I confess I have no explanations which may withstand the united criticisms of the anatomist, the physiologist, and the pathologist, but I believe (in the sense of "believing where we cannot prove") that there is a factor of referred pain in hemicrania. At the risk of unmasking the combined batteries alluded to, I shall state my view: assuming that the headache is right-sided, the afferent fibres in the branches of the right gastric vagus convey their violent irritation to the Bulb, where occurs the transference to those branches of the ophthalmic and superior maxillary nerves that innervate the orbit and side of the head. I regard the gastro-intestinal catarrh and toxaemia as the source of this irritation of the afferent vagal fibres. Just as in headache of ocular origin, the pain is referred from the eye to the forehead, and in headache of dental origin from the teeth, so in hemicrania there is pain referred from the gastro-intestinal mucosa to certain cephalic nerves.

A point of minor interest has, it seems, not been recorded—namely, a remarkable exaltation of the sense of smell. Many victims of hemicrania are aware of an unpleasantly acute sense of smell; there is a wholly abnormal exaltation of this sense. Odours ordinarily only slightly disagreeable become intolerable before the attack; the smell of cooking, frying, hot grease, etc., amounts to an olfactory purgatory and accentuates the nausea.

I am glad to see that the most recently considered causal factor—the psychic—was not forgotten in the discussion, but I infer that it did not impress the meeting with the same importance with which Dr. Crookshank has invested it.[1] I should be the last person to minimize the power of mind over matter; but I confess I have a great difficulty in understanding how an unpleasant mental state can bring about a physical condition consisting of the following syndrome: a periodic headache with a rhythm of its own and with its pain accurately localized, preceded by very definite sensory, gastric, cardio-vascular, and urinary disturbances, and consisting essentially in a unilateral dilatation of cephalic vessels. Emotional blushing is always bilateral. It is difficult to see how the supposed psychic cause accounts for either the rhythm or for the one-sidedness.

Finally, no reference seems to have been made to the social position of sufferers from migraine. So far as I can gather, they belong to the more highly educated members of society. Just as the coal-heaver does not seem to suffer from acute gout, so neither, it would seem, does he from hemicrania. We have but to remember that Haller, du Bois Raymond, George Eliot, and Sir James Simpson, to name no others, were all victims of typical one-sided headache in order to have to admit that hemicrania shares with gout the distinction of being an affliction of the aristocracy of intellect.—I am, etc.,

Dane Hill, Sussex, Jan. 18th. D. FRASER-HARRIS.

MIGRAINE AND ACETONURIA.

SIR,—May I point out to Dr. Allison (BRITISH MEDICAL JOURNAL, January 22nd, p. 165) that because glucose has a beneficial effect in cases of migraine where there is hypoglycaemia it does not follow that the sugar deficiency is the cause of the symptoms? The analytical data of such cases and the results of animal experiments point to the hypoglycaemia, acetonuria, and nervous symptoms all having a common origin in an hereditary or acquired hepatic deficiency, and it is owing to the fact that the administration of glucose enables the defective liver cells to carry

[1] *Migraine*, F. G. Crookshank, M.D., Psyche Miniatures, Kegan Paul, 1926.

out their functions more efficiently that such treatment is beneficial. Levulose and other sugars have not the same effect, and when given in large doses increase the hepatic disturbance, thus possibly accounting for Dr. Allison's experience when he took saccharose in the form of "sugar, treacle, and jams to excess." During the war, when glucose was difficult to obtain, I made many experiments to find an efficient substitute, as patients who had been doing well on regular doses of dextrose found they relapsed when cane sugar was tried instead. The most satisfactory proved to be thoroughly dextrinized starch, particularly in the form of oatmeal which had been gently boiled for six to seven hours.

Although an abnormally low blood sugar is generally met with in patients suffering from migraine, such a finding is not invariable, and dextrose is not a specific for all cases; when, however, examination of the blood and excreta reveals hypoglycaemia along with evidence of hepatic inefficiency, its effect in suitable doses is striking.—I am, etc.,

London, W.1, Jan. 22nd. P. J. CAMMIDGE.

THE DANGEROUS JUNKER.

SIR,—Another death due to the use of, it is to be presumed, a valveless Junker's inhaler is recorded. Let me appeal to the staffs and boards of all hospitals to have every valveless Junker's inhaler destroyed at once, or sooner or later they will regret it.

I have heard of many similar deaths from a mistake in assembling this apparatus when valveless. With a proper valve it is impossible for this error to take place. Properly used, and tested before using, Junker's apparatus is quite safe, but it is not fool-proof. I destroyed all the valveless Junkers at the hospital I was connected with many years ago, and since then there has been no risk of error.

The risk is eliminated by pumping through several times, pointing the tube to the floor, but when in a hurry this precaution is unfortunately too often omitted.

With hundreds of young qualified men giving anaesthetics every year a percentage will trust to the apparatus having been properly fitted up without testing it.

I have been watching this matter for years, and if this letter results in hospitals forbidding the use of a valveless Junker's inhaler I shall feel that I have assisted in saving many lives in the future. I sincerely hope this letter will produce a united effort to do away with this quite unnecessary risk. It will not appeal to the experienced anaesthetist, but let him think of the more numerous less experienced men giving anaesthetics.—I am, etc.,

Bournemouth, Jan. 26th. W. J. FOSTER, F.R.C.S.

*** The death referred to by Mr. Foster is, we assume, that of an apprentice artificer in the Royal Artillery, aged 16, which occurred in the Royal Herbert Hospital, Woolwich, and was the subject of an inquest by the coroner for South-East London. Captain E. H. W. Elkington, R.A.M.C., anaesthetist, said that the operation was for enlarged tonsils, and that for the first tonsil anaesthesia was produced by chloroform and ether given by the open method; for the second a Junker's apparatus was used, through a nostril. Owing to an error in the assembling of the apparatus by a corporal entrusted with that duty, instead of chloroform vapour liquid chloroform was injected. The patient showed signs of collapse, and although he revived he died twenty hours later from acute oedema of the lungs. A verdict of accidental death was recorded. The coroner drew attention to the need for extreme care in assembling the apparatus.

SMALL-POX AND VACCINATION.

SIR,—Dr. Killick Millard's letter in your issue of January 22nd (p. 163) contains a brief quotation from Dr. Barry's report on the Sheffield outbreak of small-pox in 1887-88 which, I think, would lead any reader not familiar with the whole of that document to infer that Dr. Barry had considered that vaccination as a measure of prevention against small-pox had been a failure. Dr. Millard is a personal friend of mine, and will, I am sure, acquit me of any intention to impute to him any deliberate misrepresentation or attempt to mislead his readers; but I feel it my duty to point out that Dr. Barry's report is one of the strongest arguments in favour of vaccination which has ever been published.

The actual figures quoted by Dr. Millard are substantially correct. At that date the population of Sheffield was estimated to be 316,288. The number of vaccinated persons was 270,055, or 97.9 per cent. of the whole; the number unvaccinated was 5,823, or 2.1 per cent.

This figure for "vaccinated persons" includes people at all ages who had been vaccinated in infancy. It follows, of course, that the great majority of these, although officially "vaccinated," were actually unprotected by vaccination. Even so, the actual figures for incidence and mortality in vaccinated and unvaccinated persons are as follows:

Vaccinated persons attacked, 4,191, or 1.5 per cent.
Unvaccinated persons attacked, 553, or 9.5 per cent.
Deaths in vaccinated persons, 203, or 0.07 per cent.
Deaths in unvaccinated persons, 275, or 4.73 per cent.

The case mortality in vaccinated persons was 4.8 per cent. and in unvaccinated persons 49.7 per cent.

The last two figures do not appear in Dr. Barry's report, but have been extracted from his figures in this office. Dr. Barry, however, gives the following figures (p. xvi):

"Of children under 10 years of age, the attack rate was—
of the vaccinated 5,
of the unvaccinated 101.
The death rate of the vaccinated was 0.09.
The death rate of the unvaccinated was 44.00."

Dr. Barry adds:

"Let me state this difference in other terms: for 100,000 vaccinated children the rate of small-pox mortality actually observed in Sheffield gives 9 deaths. For 100,000 unvaccinated children, the rate of small-pox mortality actually observed gives 4,400 deaths."

The following figures may also be quoted from p. xvii:

"Per thousand of the number of persons over 10 in each class—

The attack rate in persons twice vaccinated was ...	3
The attack rate in persons once vaccinated was ...	19
The attack rate in persons not vaccinated was ...	94
The death rate among persons twice vaccinated was	0.08
The death rate among persons once vaccinated was	1.00
The death rate among persons not vaccinated was ...	51.00"

Dr. Barry also says:

"The twice vaccinated persons over 10 years of age as compared with the unvaccinated persons of the same age living in the town, had a 31-fold immunity against attack by small-pox and had a 640-fold security against death by small-pox."

If space permitted, such quotations could be multiplied *ad libitum*; but these are, I think, sufficient to prove what were the actual facts of the outbreak in Sheffield, and what were the views of Dr. Barry, who studied the epidemic, endorsed by Dr. Buchanan, who drafted and signed the introduction to the report from which the above quotations have been excerpted.

Sheffield is again in the throes of an epidemic of small-pox, in a form which is certainly reverting from the very mild type with which we have recently been familiar to a form quite indistinguishable from "old-fashioned small-pox," with a grave and, I fear, disfiguring eruption, and in many cases with severe constitutional disturbance. The city has for many years maintained special houses for the isolation of contacts, and, of course, adequate provision has been made for the isolation and treatment of cases. I think I may claim that Sheffield has fully carried out those "modern methods of fighting the disease" which Dr. Millard states have taken the place of infant vaccination and have proved so successful. In Sheffield these measures have now failed, and we are faced with an outbreak of which no one can predict the limits.

Visiting these cases daily for purposes of diagnosis, and noting the absolute precision with which the disease singles out the unvaccinated members of the community, it is, to me, disheartening to find so eminent and so highly esteemed a colleague as Dr. Killick Millard publishing statements which will certainly be misinterpreted and misused by persons who are imbued with that curious passion called "antivaccination," a passion which I know is not shared by Dr. Millard. I use the word "passion" deliberately, with a perfectly clear recollection of Dugald Stuart's definition of "appetites, passions, and desires" in his wise but now out-of-date book on *Moral Philosophy*.

The psychology of the antivaccinist has not been

sufficiently studied. His attitude is not based on reasoning, and he, or she, cannot be convinced or converted by reason or by any amount of facts or statistics. The attitude of the antivaccinist is definitely a "passion." It is a revolt against what appears to him to be an imposition of authority, and the medical profession has failed, where in past days the Church has succeeded, in imposing a faith that it believes to be for the good of the community, largely because it has attempted to appeal to reason and not to superstition, an older and more powerful element in the mental equipment of the average man.

I have only to add that, as regards policy, Dr. Millard and I are quite in accord. He agrees that in emergencies such as that with which I am at present faced, vaccination and revaccination are essential weapons against the disease. I agree that our present system of nominal compulsion with unlimited "exemption" is chaotic and idiotic. I should like to see it abandoned, and power given by Parliament to the Minister of Health to declare any area in which small-pox exists to be "an infected area," and to make regulations dealing with such areas which should include compulsory vaccination and revaccination of the whole population in such specified areas.—I am, etc.,

FRED. E. WYNNE,
Medical Officer of Health, Sheffield, and Professor of Public Health, Sheffield University.

January 25th.

SIR,—Dr. A. F. Cameron suggests that my opinions about vaccination have apparently undergone considerable change. I can assure him that there has been no change. My faith in vaccination remains just as strong as ever—my faith in much of the current teaching about vaccination remains still rather weak.

Dr. Cameron inquires (though I rather doubt if he is really seeking enlightenment) as to my exact meaning when I say: "Under these circumstances vaccination proved quite incapable of preventing widespread and fatal epidemics." Do I mean by "vaccination," he asks, "compulsory infant vaccination"? Certainly I do. My whole letter was dealing expressly with the question of compulsory vaccination, and infant vaccination is the only form that has ever been compulsory in this country. I had hoped that the context made my meaning quite clear.

There is, however, one small correction in my letter which I should like to make. I said that in Leicester there had been no death from small-pox for twenty-one years. Actually the last death occurred in 1904, so that it should have been twenty-two years. I had forgotten that we had entered upon another year.—I am, etc.,

Health Offices, Leicester, Jan. 29th C. KILLICK MILLARD.

GOOD AND BAD DIETS.

SIR,—I can confirm all Dr. Clarke's contentions (November 13th, 1926, p. 906) regarding the practicability of giving infants meat, fruit, and other foods much earlier than is the custom. The wide physiological capabilities of the young human digestive system are not sufficiently appreciated.

May I draw attention to two important truths regarding the food of the nursling and weaned child?

1. The human palate and digestive system are extraordinarily adaptable. If the process be begun early enough they can be educated to like and to digest with varying degrees of efficiency foods chosen from an almost infinite range. This wide adaptability would appear to apply to all omnivorous mammals—rat, pig, anthropoid, man. Consider how readily the large anthropoid takes to refined, civilized human diet. Hence the supreme importance of educating the human palate and digestive system from an early age to like and to digest efficiently such foods as experience has shown are most conducive to health. Here I may point out a disadvantage attaching to sweet foods—namely, that they tend to spoil the child's appetite for healthy unsweetened foods. This matter of educating the child's palate is of the utmost importance. On no account must we pamper the child's appetite: our aim must be to create a healthy appetite for healthy food.

2. We are all too apt to belittle the masticatory capabilities of the nursling after the seventh month and of the weaned child. Even when the infant is cutting its first teeth it should be allowed certain hard foods to bite at. I know of children who soon after the twelfth month have been capable of demolishing with avidity hard dry crusts which many a British adult would shy at for fear of damaging his teeth.

Much the most important reform needed in our diet pertains to the softness of the vegetable portion of it. I say deliberately that it would be difficult to exaggerate the importance of lessening the quantity of pappy, pultaceous, and spongy farinaceous foods we give our children, and of supplying them with an adequate share of vegetable food which compels efficient mastication, thus allowing the jaws, nasal passages, and salivary glands to develop as nature intended them, and the teeth to take up their proper positions in the gums without jamming. It is nothing less than a national duty to bring this elementary truth home to the rising generation of medical men. One of the dangers of the superscientific age in which we live is that it is apt to prevent us from seeing the wood for the trees.—I am, etc.,

London, W.1, Jan. 28th. HARRY CAMPBELL.

SPINAL ANAESTHESIA FOR OPERATIONS ON HERNIA.

SIR,—I have read with great interest Mr. Geoffrey Keynes's admirable address on "The modern treatment of hernia," published in the BRITISH MEDICAL JOURNAL of January 29th (p. 173). While entirely agreeing with him that a general anaesthetic should be avoided wherever possible, I would submit that spinal analgesia offers certain very definite advantages over the local anaesthesia that he employs. I have for some time past conducted all hernia operations under spinal analgesia, and have been much impressed by the convenience and facility of this method. Even umbilical herniae can be readily dealt with in this manner, the lumbar puncture being performed between the third and fourth lumbar vertebrae in the usual way.

In support of my contention, I would adduce the following principal advantages of spinal over local anaesthesia:

1. Greater simplicity—in that a single injection suffices to anaesthetize the whole field of operation. A great saving of time is thus effected, especially where "living sutures" of fascia lata are employed, for the cutting of these necessitates a second series of injections in the case of a local anaesthetic.

2. More complete relaxation—and thus an abolition of the respiratory movements of the abdomen, and an entire avoidance of "blowing out" of the intestines as may happen with a local anaesthetic.

3. Anaesthesia is probably of greater duration by spinal administration. In support of this I would cite a case of mine in which living sutures were used to repair a very large scrotal hernia with adherent sac; the operation lasted two and a quarter hours, and the anaesthesia was still perfect at the end of that time.

I may add that it is my custom to give a pre-operative injection of hyoscine and morphine; after this, the patient frequently sleeps throughout the operation.—I am, etc.,

London, Jan. 30th. H. A. H. HARRIS, F.R.C.S.Ed.

THE HISTORY OF DIPHTHERIA.

SIR,—In his address upon changes in types of diseases, reported in the JOURNAL of January 15th (p. 87), Sir Humphry Rolleston mentions that diphtheria appears to have been first described by Bretonneau of Tours in 1821. I have a little book entitled *Cases and Practical Remarks in Surgery*, by Benjamin Gooch of Norfolk, 1758. Gooch was the inventor of the splinting which bears his name. He describes "a species of tumor called by the Common People 'The Mumps,'" which was epidemic in Norfolk in 1740, after the hard winter of 1739, and which Gooch says he had never seen or heard of before and which was rife all the summer ("cold, dry, and unfruitful"), lasting until the autumn of 1741; he then says that, after the disappearance of this disease, the malignant sore throat first appeared. He states that this had been "accurately described by three very learned physicians." The outbreak occurred in the country about ten miles from Norwich and lasted more than ten years, but "raged and was most mortal" in 1745-46.

From his observations there appeared to be an analogy between this disease and that among horned cattle, which, he says, had been present for over forty years. He adds that Bonetus, taking notice of such a disease in the throat, says that it was preceded by a plague among cattle, "the pathognomonic of which also appeared in the throat."

It is perhaps of interest that the outbreak mentioned by Gooch occurred more than twenty years before the date of Francis Home's essay mentioned by Fleet Surgeon Home in your issue of January 22nd.—I am, etc.,

Wallasey, Jan. 26th. SEYMOUR W. DAVIES.

LAW AND TRADITION OF MEDICAL PRACTICE.

SIR,—While reluctant to continue a controversy in the atmosphere of narrow professionalism to which your last comments have reduced it, we feel bound to ask you to publish a brief and final reply.

We have been astonished at your comments, because there is nothing in our book which is not sanctioned by the best and the latest authorities. If your comments are correct, all the textbooks in the leading medical and law libraries are more unreliable than we supposed. This is surprising in view of the commendation of existing works contained in your review.

We cannot, of course, ask for sufficient space to answer your criticism in detail, but are prepared privately to produce our authority for any statement made in our book. At present we content ourselves with pointing out that it is no answer to say of an objectionable practice—for example, employment of unqualified dispensers—that thousands of medical men do this. It is nevertheless true to say that the practice is contrary to the best traditions of the profession and the "spirit of the law." Nor need one be a philosopher, or even a lawyer, to understand that spirit, which was correctly appreciated in a resolution regarding a similar point passed by the General Council on December 2nd, 1901, as being a motive to avoid any practice "fraught with danger to the public."—We are, etc.,

WILLIAM SANDERSON,
Lincoln's Inn, Jan. 29th. E. B. A. RAYNER.

*** We print Messrs. Sanderson and Rayner's letter, although it contains no attempt to justify the inaccuracies for which we have shown the writers to be responsible. The "best and the latest authorities" for what the General Medical Council has said or has not said are the official "Notices" issued by the Council, and not unnamed writers, whether ancient or modern. To take the single point selected by Messrs. Sanderson and Rayner, they have affirmed that the General Medical Council has condemned the employment as dispensers of persons technically "unqualified." In rebuttal we have alleged that the Council has recorded no such decision, and Messrs. Sanderson and Rayner allow the case to go by default. To say that such a practice is "objectionable," with the implication that it is "fraught with danger to the public," is another and a different proposition. Plainly this is a matter of opinion, and on such a point Messrs. Sanderson and Rayner's view may or may not be of some importance. The attempted substitution of a new proposition for one that has been successfully challenged is a familiar device of the distressed debater, and when practised by lawyers may perhaps be regarded in non-legal circles as an exercise in "narrow professionalism." The fact remains that the original statement by Messrs. Sanderson and Rayner was incorrect, and that they have not found sufficient grace to admit their error. And what is true in this particular instance is true also of the other inaccuracies to which we have drawn attention.

CANCER AND TRAUMA.

SIR,—In reply to Sir Lenthal Cheatle (January 29th, p. 216), may I state that for some months I have been collecting cases of cancer arising in wounds received during the late war, and so far have obtained three undoubted cases? Probably many more could be found, and I should be glad to obtain particulars of them. They are of interest as throwing light upon the length of the period of cancer induction in man.

The subject of cancer arising in scars other than those due to burns is discussed in the *Cancer Review*, 1926, 1, pp. 108 and 183 (abstract 169 of a paper by Bang, and abstract 327 of one by Iwamoto); and 1927, 2, p. 55 (abstracts 102 and 103 of papers by Tow and Itoh and by Dubreuilh and Maginel respectively). Since the latent period seems to be from twelve to forty years, it is still perhaps somewhat early to expect many cases of malignant disease arising from wounds received in the last war.—I am, etc.,

London, S.W.3, Jan. 31st. H. J. B. FRY.

Obituary.

T. R. BRADSHAW, M.D., F.R.C.P.,

Consulting Physician to the Royal Infirmary, Liverpool.

THE medical profession in Liverpool mourns, in the death of Dr. T. R. Bradshaw, on January 25th, the passing of a distinguished physician and a well loved colleague.

He was educated at Trinity College, Dublin, where he graduated M.A. in 1878 and M.D. in 1882. He became M.R.C.P. in 1890 and was elected Fellow in 1904. He was originally attracted to Liverpool by the presence there of his relative, the late Dr. Waters, physician to the Royal Infirmary. After serving as house-physician to the Infirmary he was elected a member of the honorary staff; he most worthily sustained its best traditions by the lofty standard of work and of life which he ever held before himself. From these standards he never swerved; medical science is richer as the result of his work, and colleagues, friends, and patients through contact with him sensed at once a gentleman and a gentle man. He was a most conscientious and painstaking worker, and always manifested the utmost regard for his patients—hospital no less than private. Many of his papers were of marked interest; he never grudged labour in their production, and all were expressed in polished English; by his original, laborious, and long continued work on myelopathic albumosuria in particular he clarified a previously obscure position and made a definite addition to medical science. All his medical work was sound and reliable, and in at least one instance (that of albumosuria) it was pioneer. But distinguished as that work was, it was not because of it—or not mainly because of it—that he was admired and is now mourned. It has truly been said of him that he never said an unkind word about anyone; he was a splendid colleague and loyal to a degree. Medicine is the richer by his work, and the man himself is enshrined in the hearts of those who knew him.

He was President of the Liverpool Medical Institution in 1910 and 1911, and became university lecturer in clinical medicine. He had also been physician to the Stanley Hospital, Liverpool, and consulting physician to the Liverpool Samaritan Hospital for Women. For many years he took an active interest in the work of the British Medical Association; he was a member of the Council of the Lancashire and Cheshire Branch for three periods between 1892 and 1921, a member of the Parliamentary Bills Committee from 1898 to 1902, and a member of the Central Council from 1906 to 1909. He was a member of the Executive Committee of the Liverpool Central Division from 1904 to 1909, and of the Liverpool Division in 1912 and 1917-18. He was a member of the Representative Body in 1919-20; in 1912 he was vice-president of the Section of Medicine at the Annual Meeting in Liverpool. During the war he did strenuous work at the First Western General Hospital, with the rank of major. When he retired he went to reside at Mold, in Flintshire. The funeral took place on January 28th at the old country church at Nerquis, near Mold.

T. RIDLEY BAILEY, M.D., C.M.ED.,

Medical Officer of Health, Bilston.

BY the death of Dr. Ridley Bailey, briefly announced in our last issue, the profession in the Midlands has lost one of its most valued members, who for many years took an enthusiastic part in the local and central work of the British Medical Association. He died on January 25th at the Queen Victoria Nursing Institute, Wolverhampton, where he had lately undergone a severe operation.

Thomas Ridley Bailey, the son of Richard Bailey of Durham, was born on October 17th, 1859. He studied medicine at the University of Edinburgh, graduated M.B., C.M. in 1882, and proceeded M.D., with honours, in 1887. Soon after graduation he made his home at Bilston, Staffordshire, where he began general practice in partnership with the late Dr. Larkin, and in 1885, when only 25, was appointed part-time medical officer of health for the urban district, a post he held until the time of his death. He was also medical officer and public vaccinator under the Wolverhampton Union, medical officer to the Bilston Isolation Hospital, school medical officer, and certifying factory surgeon. His active work for the British Medical Association commenced in 1888 when he became a member of the Staffordshire Branch Council, and from that time onwards he was prominently associated with the work of the Branch, holding office as its President in 1896 and vice-president in the two following years. He was vice-chairman of the South Staffordshire Division in 1907 and 1924, and chairman in 1908 and 1922, and had acted as deputy representative of the Division in the Representative Body since 1921. For many years also he was a familiar figure at the headquarters of the Association in London as a member of the Insurance Acts, Medico-Political, Public Health, and Welsh Committees, and of various subcommittees. He served as chairman of the Public Health Committee in 1920-21, and again in 1924-26, and since his election to the Central Council in 1920 had attended regularly at all Council meetings. The esteem in which Dr. Ridley Bailey was held by his local colleagues is further shown by his appointment as chairman of the Staffordshire Local Medical and Panel Committee, and his long period of office as representative of the medical profession upon the Insurance Committee for the county.

He was for many years a fellow of the Society of Medical Officers of Health, a past-president of its Midland Branch, and in recent times one of the representatives of the British Medical Association on its council. He was also a member of the council both of the Poor Law Medical Officers Association and the Association of Public Vaccinators.

Dr. F. MILNES BLUMER of Stafford, a close friend of forty years' standing, sends the following personal appreciation:

Of a happy, bright, and cheerful disposition, Ridley Bailey attracted to himself a large circle of friends, not only in his adopted county of Staffordshire, but also among the many men from all parts of the country with whom he became associated on the various public bodies on which he served. His strong personality was manifest wherever he foregathered with his friends, and his almost buoyant spirits and general optimism, combined with a dry sense of humour, made him a general favourite. He was a shrewd judge of character, and had only contempt for those who entered public life merely from ulterior and personal motives. Such a man was bound to have strong likes and dislikes, and, while he was careful to suppress the latter, the former were shown in the many strong and lasting friendships he made. As a public speaker few medical men could equal him. He had a great command of language, which he phrased with an elegance pleasing to listen to, and he spoke with an earnestness both impressive and convincing. At social functions his oratory was always an outstanding feature. Quite early in his professional life Ridley Bailey was attracted by medical politics, and for forty years he has devoted his spare time to the service of his professional brethren. That such was appreciated is manifested not only by the number and variety of public bodies upon which he served, but also by the fact that he rose to the highest positions in them all. Clear thinking and far vision were natural gifts with him, and when he had come to a decision which he thought was right he would support it with clear argument and determination, which won for him much support. His grip on public business was really astonishing, seeing that throughout all these years he was engaged in busy general practice and in public health work as M.O.H. for Bilston. He was an exceptionally good chairman, firm and scrupulously fair—a pattern in conduct for many to copy. Ridley Bailey worked up to the day on which he entered t nursing home, and in his last illness he approached t inevitable end with that peacefulness and courage whi come to the man of a strong faith such as he had, a with the knowledge that his life's work had been spe —and well spent—in the service of others.

The funeral service was held at St. Leonard's, Bilston, January 28th. There was a large gathering of councille and officials from Bilston, and the medical profession w represented by Sir John Robertson (M.O.H., Birmingham Dr. Waddell (Chairman, South Staffordshire Division Mr. A. W. Nuthall, representing the Council of the Briti Medical Association; Dr. Craig (Chairman of the Wolv hampton Panel Committee); Dr. Jolly (M.O.H., Wolv hampton); Dr. Dean (M.O.H., Willenhall); Dr. Tibbet (Staffordshire Panel Committee); Mr. Cholmeley (Wolv hampton), and many others. The interment took place Cheltenham.

J. C. UHTHOFF, M.D., F.R.C.S.,

Consulting Physician, Sussex Eye Hospital, Brighton.

DR. JOHN CALDWELL UHTHOFF, formerly a well know practitioner in Brighton, died on January 19th at Bourn mouth. He received his medical education at Guy Hospital Medical School, took the diploma of M.R.C.S.En in 1877, and graduated M.B., B.S.Lond. in 1878, with t University scholarship and gold medal in forensic medicin the gold medal in materia medica and chemistry, a first-class honours in medicine and obstetric medicin He proceeded to the M.D. in 1879, and obtained t F.R.C.S.Eng. in 1881. Dr. Uhthoff was for a time Member of the Royal College of Physicians, but as went into partnership in 1894 he resigned the diploma accordance with the rule then existing. The diploma w restored to him at his request in 1896, but he aga surrendered it in 1908. He had a large practice Brighton, was at one time physician to the Royal Suss County Hospital and the Sussex Eye Hospital, a ultimately became consulting physician to the latt institution. While continuing to practise as a gener physician he gave particular attention to ophthalmology, specialty in which he attained great distinction.

He took great interest in the work of the British Medic Association, was a member of the South-Eastern Bran Council, 1888-93, chairman of the Brighton Division 1920, and a member of the Sussex Branch Council in 192 When the British Medical Association held its Annu Meeting at Brighton in 1886 he was one of the secretari of the Section of Pathology and Bacteriology, and in 191 when the Association again held its Annual Meeting Brighton, he was a vice-president of the Section Pharmacology, Therapeutics, and Dietetics. He retir from practice in Brighton some years ago, and went reside in Bournemouth, but did not lose his interest medical affairs; at the time of his death he was repr sentative of the Bournemouth Division on the Dorset a West Hants Branch Council.

He was buried at Hove on January 24th, when many colleagues, including Drs. Jowers, Whittington, Fletch Chadborn, Bowring, Hunt (representing the Brighton a Sussex Medico-Chirurgical Society), L. A. Parry (rep senting the Sussex Branch of the British Medical As ciation), and A. G. S. Mahomed (representing t Bournemouth Division of the British Medical Associatio attended as a last tribute of respect.

Dr. L. A. PARRY, Honorary Secretary of the Suss Branch of the British Medical Association, has been go enough to send us the following tribute: The death Dr. Uhthoff came as a great shock to his old friends Brighton, where he will be greatly mourned. We of t profession well remember his kind and courteous ways us all. I personally owe him many debts of gratitude thoughtful actions. As Chairman of the Brighton Divisi of the Association he was always helpful to us in our wo and I could consult him on any matter and be sure obtaining good advice. He had an enormous practice. I patients held him in the very highest regard. During t

ar he acted as medical officer to one of the hospitals stablished in Brighton, giving his best services to those nder his care. He was in the best sense of the words real English gentleman. In Brighton we shall always emember him as one who enhanced the reputation of our rofession in the town and was always willing and wishful o give us any advice and assistance that lay in his power.

NIELS THORKILD ROVSING,

Late Professor of Clinical Surgery, Copenhagen.

HE death of Professor Rovsing has robbed the Danish edical profession of a striking and forceful personality. is always difficult to say how much anyone's success in fe depends on character and personality and how much a intellect. But in Rovsing's case there can be no doubt hat, both in force of character and weight of intellect, he as a head and shoulders above his fellows. He was born 1862, and at the age of 23 had already passed his final xaminations in medicine. Early in his career he began o think bacteriologically in his surgical work, and in the rst paper he published, in conjunction with Dr. Heyn, he hattered the reputation of iodoform as an antiseptic pplication. "Shattered" is a word peculiarly apt in any ccount of Rovsing's writings, for fighting was as the breath f his nostrils, and he was at his best when attacking time-onoured teaching of the errors of which he had no doubt. ltogether he published about 200 papers, remarkable for heir lucidity and convincing logic. Time may prove some f Rovsing's teachings to be mistaken, but his method of resenting them will always be a model. Fairly early in is career he acquired an interest in the weekly medical ournal *Hospitalstidende*, which he later owned and ltimately gave to the Danish Medical Society. In 1899 e was appointed professor of operative surgery, but, uriously enough, this appointment did not bring with it ospital beds, though it did entail teaching. To repair this ffect he started a private surgical nursing home in the ne year, and its enlargement a few years later, with the ovision of an *x*-ray laboratory, was a testimony to the ficiency with which this aspect of his work was conducted. 1904, at the early age of 42, Rovsing was put in charge the Frederiks Hospital as senior surgeon, and in 1905 s agitation for better surgical accommodation in Copen-gen was the beginning of the present Rigshospital, which as opened five years later.

Rovsing's work as a pioneer in surgery concerned chiefly e lower abdomen. Early in his career his attention was rected to the subject of cystitis; patients suffering from were at this time treated for the most part in medical rds, with infusions and decoctions. Rovsing set himself e task of studying the causes of decomposition of urine d its prevention. His work on tuberculosis of the inary tract also gained him an international reputation. iseases of the gall bladder, and gall stones in particular, nstituted another field in which he greatly distinguished mself. He was an active organizer, and he was one of e founders of the Danish Surgical Society. The recipient many honours in his own country, he was also an morary member of the Edinburgh Medico-Chirurgical ciety and of the Association of Surgeons of Great Britain d Ireland. In 1926 severe heart disease with serious gus of cardiac insufficiency forced him to retire from his st at the University; after some improvement during the mmer he developed signs of malignant disease of the ynx. It was characteristic of him that, a few days after severe operation for this condition, he began to work gain. He did not, however, tolerate a course of *x*-ray eatment well, and he died on January 14th, a flagging art failing to respond to the calls made on it. One of his lleagues, Holger Strandgaard, who was in daily contact ith him for seven years, writes in *Ugeskrift for Laeger*, e journal of the Danish Medical Association, as follows: In his relations with assistants, nurses, and the rest of s staff he approached the ideal. He included us all in s work, made us participate in it, and was never afraid let us feel that he appreciated the help that was given m. And so he made the great machinery work without iction."

Medico-Legal.

OPERATION WITHOUT CONSENT.

AN action was heard last week at the Liverpool Assizes (Civil Court) before Mr. Justice Wright, in which a hospital patient claimed damages against a surgeon for alleged negligence by performing an operation without her consent.

The plaintiff was Mrs. Hilda Maddocks, aged 28, and the defendant, Mr. John St. George Wilson, honorary surgeon to the Samaritan Hospital for Women, Liverpool. Mr. Wilson was represented by Mr. J. E. Singleton, K.C., and Viscount Erleigh (instructed by Messrs. Hempsons).

The plaintiff's case was that she went to the Samaritan Hospital for an internal complaint, and while being examined by Mr. Wilson under an anaesthetic a serious operation was performed upon her. She declared that she had not been previously asked, nor had she given, her consent to an operation. Since then she had had to undergo two further operations, and the wound caused by the first operation had not yet healed. There was no suggestion that the operation had not been skilfully performed. It was submitted on behalf of the defendant that although he had not the patient's express consent to operate he had her implied consent.

The plaintiff gave evidence bearing out the opening statement by her counsel, Mr. Rice Jones. In cross-examination she admitted that had she been told beforehand that an immediate operation was necessary she would have consented, but she would first have liked to get the consent of her husband. She agreed that the initial operation had probably saved her life.

Mr. St. George Wilson, giving evidence on his own behalf, said that it was not his duty to obtain the patient's permission for an operation; that devolved upon the hospital staff. The woman proved to be suffering from cystitis, and her condition was acute. There was risk of death sooner or later through ascending infection, and every day the infection persisted the greater was the danger. She was in severe pain. Had he not operated at once he would have had to do so a day or two later, when there would have been serious danger of further septic poisoning. The purpose of the operation was to save, if possible, other organs from becoming infected.

Dr. S. S. Barton, who assisted Mr. Wilson at the operation, said that the woman's condition needed an immediate operation; and Mr. H. C. W. Nuttall, surgeon to the Royal Southern Hospital, to whom Mr. Wilson sent the patient after she had been five weeks in the Samaritan Hospital, described her critical state when he operated upon her.

Mr. F. A. Jeans, surgeon to the Liverpool Royal Infirmary, who was called by the defence as an expert witness, said in reply to questions by the judge, that giving an opinion purely on the history of the case, he felt he would have done exactly the same as Mr. Wilson, who acted in the interests of the patient. In this case he had no doubt the right course had been taken. The operation would give immediate relief to the tension which was causing the septic poison to be absorbed.

Mr. Justice Wright, in the course of his summing-up, remarked that if a doctor performed an operation without the patient's consent, believing that by so doing he was saving the person's life, he had to take the risk of satisfying a jury that he had done what was right in the circumstances.

The special jury, after a retirement of three-quarters of an hour, returned a verdict in favour of the defendant, Mr. Wilson, adding a rider to the effect that doctors should not operate without the consent of the patient. To this the judge added the corollary —"if it can be avoided."

The Services.

DEATHS IN THE SERVICES.

LIEUT.-COLONEL ROBERT FRAZER STANDAGE, C.I.E., Bombay Medical Service (ret.), died suddenly in London on January 15th. He was born in 1868, and received his medical education at St. Bartholomew's Hospital Medical College, where he gained the Bentley surgical prize in 1890. He took the M.R.C.S. and L.R.C.P.Lond. in 1889, the M.R.C.P.Lond. in 1907, and the F.R.C.S.Eng. in 1920. After filling the posts of house-surgeon and house-physician at the Metropolitan Hospital, he entered the I.M.S. as lieutenant in 1895, became lieutenant-colonel after twenty years' service, and retired in January, 1926. His first five years were spent on military, plague, and famine duty, and for the last he received the thanks of the Bombay Government in 1897. He served in the Uganda mutiny in 1897-99, was mentioned in dispatches, and received the medal with a clasp. In December, 1900, he was appointed Residency surgeon at Bangalore, and in November, 1902, Residency surgeon of Mysore, where he remained till the end of his service, except during the great war. He was on military duty from July, 1917, to March, 1919, serving in British, Portuguese, and German East Africa, in Nyasaland, and Northern Rhodesia; he was mentioned in dispatches in January, 1919, and received the medal. In January, 1922, he was gazetted C.I.E., and last year received also the Order of St. John of Jerusalem. In his early years he was a good cricketer and a keen shikari. On retirement from the I.M.S. he joined a friend in practice at Venice. He married in 1902, and is survived by his widow and one son.

Universities and Colleges.

UNIVERSITY OF OXFORD.

THE following degree days have been announced for the remainder of the academic year: Saturday, February 19th; Saturday, April 9th; Thursday, May 5th; Saturday, June 11th; Friday, July 1st; Saturday, July 23rd; Saturday, August 6th.

At a congregation held on January 27th the following medical degrees were conferred:

B.M.—C. S. Broadbent, J. G. A. Davel, L. O. F. Fysh, A. H. Gale, Rosaleen L. Graves, C. L. Harding, R. A. Haythornthwaite, R. C. Hodges, C. W. Hope-Gill, R. Illingworth, T. M. Ling, G. E. Macdonald, R. G. MacGregor, W. F. H. Ray, W. D. B. Read, D. A. Robertson, E. M. Wright.

UNIVERSITY OF CAMBRIDGE.

SIR HUMPHRY ROLLESTON, Bt., M.D., Regius Professor of Physic, has been appointed by the Senate to represent the University at the celebration in London next April of the centenary of *Lord Lister's birth*.

At a congregation held on January 29th the degrees of M.B. and B.Chir. were conferred on R. T. Mummery.

UNIVERSITY OF LONDON.

AT a meeting of the Senate, held on January 26th, Mr. H. L. Eason, C.B., C.M.G., M.D., M.S., was appointed a member of the General Medical Council, and Sir William J. Collins, K.C.V.O., M.S., F.R.C.S., was elected a member of the Sanitary Institute and Sanitary Inspectors' Examination Joint Board. Sir Holburt J. Waring was elected the representative at the celebration of the centenary of the birth of *Lord Lister* to take place in London on April 5th. Mr. M. E. Delafield, M.B., B.Ch., was appointed the representative of University College at the Royal Sanitary Institute Congress to be held in July next at Hastings.

UNIVERSITY OF MANCHESTER.

THE Council of the University has appointed Dr. William Fletcher Shaw, who has been professor of obstetrics and gynaecology in the University since May, 1925, as professor of clinical obstetrics and gynaecology in succession to the late Professor W. E. Fothergill. The Council has also appointed Dr. Daniel Dougal, at present Lecturer in Obstetrics and Gynaecology in the University, to the chair of obstetrics and gynaecology vacated by Professor Fletcher Shaw.

UNIVERSITY OF GLASGOW.

THE following candidates have been approved for the degrees indicated:

CH.M.—James R. Learmonth.
PH.D.—John Donald, M.B., C.M.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN ordinary comitia of the Royal College of Physicians of London was held on Thursday, January 27th, the President, Sir John Rose Bradford, being in the chair.

Membership.

The following candidates were admitted to the membership:

[illegible] m Arthur Bourne, L.R.C.P., [illegible] ohn Alexander Charles, [illegible] Thomas Reginald Davies, M.B.Lond., L.R.C.P., Charles Sydney Douglas Don, M.B.Aberd., John Hartley Gibbons, L.R.C.P., William Gunn, M.B.Aberd., George Stiven Halley, M.D.St. Andrews, [illegible] M.B.Oxf., Alexander Mills Kennedy, [illegible] Edward Kiebor, M.B.Lond., L.R.C.P. [illegible] Kohiyar, M.B.Bombay, M.D.Lond., [illegible] Kohmstam, [illegible]

Licences.

Licences were granted to the following 126 candidates who had passed the necessary examinations and conformed to the by-laws and regulations:

W. M. Abdel-Malek, G. M. Addison, J. C. B. Allen, J. S. Alman, H. Archer, F. F. Augsburger, M. T. Aung, G. C. Babington, D. H. Belfrage, R. N. Bery, R. V. Bowles, [illegible] Bruce, S. M. Burrows, C. P. Campio [illegible] Clark, H. H. Cohen, E. Colin Ru [illegible] *Geraldine H. Cowie, R. D. Curran, [illegible] Dear, J. H. A. Donnelland, A. O. [illegible] *Enid C. Evans, E. S. Evans, F. M [illegible] G. M. FitzGibbon, A. Mc[illegible] Ford, D. Gamsu, H. G. [illegible] us, S. W. Hardwick, Wilfred V [illegible] L.J. Henry, E. M. V. Hensma [illegible] on, *Isabelle R. Humphreys-C [illegible] C. Jepson, T. M. Jones, V. Kathirgamatamby, M. S. Katre, F. Kellett A. B. Kettle, P. N. Lahiri, D. T. Lewis, I. N. Lewis, D. W. Lindech [illegible] wy, *Joyce McConnell, W. S. Macla[illegible] n, D. J. Macvish, M. Malk, E. [illegible] W. Melville, R. L. Midgley, I. A. Mill[illegible] *Mairaret Mitchell, J. K. Monro, W. C. Munro, J. C. Neely, R. Nicklin, *Joan Nixon, W. C. W. Nixon, *Mary O'Leary, *Greta E. Olsson, *Catherine J. Ormerod, R. Pearce, N. F. Pearson, R. S. Pilcher, T. J. Pittard, L. G. J. Pitt-Payne, *Aileen M. S. Pollock, J. C. C. Poole, C. L. Potts, I. M. Preston, W. P. Purvis, J. S. Rake, *Marion Ravell, L. A. Richardson, N. Rizkalla, *Enid H. Rockstro, E. E. F. Rose, N. Rosen, G. E. Rowan, A. H. Russell, C. G. A. Sadler, C. H. St. Johnston, T. F. McN. Scott, D. H. Smith, H. M. Soar, R. Stanton, *Kathleen M. Stuart-Harris, C. N. Suter, C. B. V. Tait, H. Teitelbaum, H. D. Tonking, J. R. H. Towers, C. G. Townsend, A. G. Tribe, A. S. Wallis, *Edith V. E. Whidborne, N. J. Williams, G. P. Williams, W. D. Williams, R. W. Windle, C. E. Woodrow, F. H. Woolley.

* Under the Medical Act, 1876.

Diplomas in Special Subjects.

Diplomas in the subjects indicated were granted jointly with the Royal College of Surgeons to the following:

D.P.H.—M. I. [illegible] Davies, [illegible] Forsyth, [illegible] Kynaston, [illegible] G. O. Milt [illegible] D. Owen, A. C. T. Perkins, Q. M. Said, J. B. Samson, T. G. N. Stokes, C. I. Streich, Elsie Warren.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.—M. Abd al-Hakeem, D. [illegible] E. A. Bennet, J. [illegible] Heron, F. L. Mc [illegible]

DIPLOMA IN OPHTH[illegible] Aynsley, Doris M. [illegible] J. C. Gillespie, [illegible] G. D. E. Jones, [illegible] Richardson, A. [illegible] *Stenhouse*, D. A. Williams.

DIPLOMA IN LARYNGOLOGY AND OTOLOGY.—R. T. Desai, L. W. Johnston, O. F. A. Krause, C. S. Macdougall, J. E. G. McGibbon, N. M. Rao, T. Williams.

Appointments and Resignations.

Dr. W. C. Bosanquet, Dr. J. H. Sequeira, Dr. F. Craven Moore and Dr. J. A. Nixon were elected councillors on the nomination of the Council.

Sir Francis Champneys was reappointed a representative of the College on the Central Midwives Board.

The resignation of Sir Humphry Rolleston of the post of representative of the College on the General Medical Council was received. Dr. E. Farquhar Buzzard was elected as his successor. A vote of thanks was accorded to Sir Humphry Rolleston for his services.

Dr. Stanley Barnes was appointed a representative of the College on the Court of Governors of the University of Birmingham in place of Dr. A. F. Voelcker, whose term of office had expired.

Dr. J. H. Abram was reappointed a representative of the College on the Court of Governors of the University of Liverpool.

The resignation of Sir William Hale-White of the post of representative of the College on the Central Council for District Nursing in London was received, and Dr. A. S. Woodwark was elected in his place.

The acceptance by Mr. F. H. Maugham, K.C., of the post of Senior Standing Counsel to the College was reported.

Dr. S. Monckton Copeman was appointed to represent the College at the Congress of the Sanitary Institute to be held at Hastings in July, 1927. The President was elected a delegate to the celebration of the Lister centenary in April, 1927.

Lecturers.

The President announced that he had appointed Dr. J. F. Gaskell to deliver the Bradshaw Lecture for 1927, and that the Council had appointed Dr. F. A. E. Crew, of the Animal Breeding Research Department of Edinburgh University, to be Milroy Lecturer in 1928.

Communications.

Communications were received from the Ministry of Health asking the College to nominate a representative to serve on an advisory committee of clinical experts to consider the details of the proposed alterations to be suggested by the British Government [illegible] ion of the international list of causes [illegible] of the League of Nations at Geneva. [illegible] ointed.

Revised By-laws.

The revised by-laws were considered for the first time.

The President then dissolved the comitia.

SOCIETY OF APOTHECARIES OF LONDON.

THE following candidates have passed in the subjects indicated:

SURGERY.—G. W. Ayres, B. Best, N. S. J. Roberts (Section II), B. Rosenzvit, M. T. Y. Selim, W. D. Williams.

MEDICINE.—L. G. Apps, L. O. Jaggassar, L. W. Rose, S. E. Tremellen, S. Wray.

FORENSIC MEDICINE.—L. G. Apps, W. A. A. Collington, S. E. Tremellen, E. H. Waller.

MIDWIFERY.—G. W. Ayres, P. V. Bamford, R. Bobo, S. K. Rigg, K. Roberts.

The diploma of the Society has been granted to Messrs. R. Bobo, L. O. Jaggassar, K. Roberts, S. E. Tremellen, and W. D. Williams.

Medical News.

A GENERAL meeting of the subscribers to the Hamilton Drummond Memorial Fund will be held in the library of the Royal Infirmary, Newcastle-on-Tyne, on Monday next, February 7th, at 7.30 p.m., in order to approve a scheme for the memorial, and to appoint trustees for the fund and an executive committee.

THE *Hunterian Oration* to be given by Sir Berkeley Moynihan on Monday, February 14th, at 4 p.m., may perhaps be looked upon as inaugurating the course of lectures at the Royal College of Surgeons of England for this year. On Wednesday, February 16th, Mr. Ernest M. Cowell will give a lecture on the surgery of hernia, and on Friday, February 18th, Mr. A. H. Southam of Manchester will lecture on retained testis in childhood. Other lectures will follow on Mondays, Wednesdays, and Fridays until Wednesday, March 2nd, when Sir Arthur Keith will begin a series of six demonstrations of recent researches carried out in the museum. The final lecture of the course will be given on Monday, March 21st.

AT a meeting of the Royal Sanitary Institute, to be held at 90, Buckingham Palace Road, S.W., on Tuesday, February 15th, a discussion on immunization against diphtheria will be opened by Dr. William Robertson, medical officer of health, Edinburgh. The chair will be taken at 5.30 p.m. by Sir Arthur Newsholme.

HIS ROYAL HIGHNESS THE PRINCE OF WALES, patron of the Mental After-Care Association, has consented to preside at a meeting of the association at the Mansion House, on Thursday, March 31st, at 3 p.m.

THE next quarterly meeting of the Royal Medico-Psychological Association will be held on Wednesday, February 16th, at Cheshire County Mental Hospital, Parkside, Macclesfield. Members will spend the morning in visiting the wards of the admission hospital, the private patients' villa, and in witnessing a demonstration of the psycho-galvanometer. In the afternoon Mr. T. H. Pear, M.A., professor of psychology in the University of Manchester, will read a paper on visual imagery, with special reference to hallucinations.

AT a meeting of the Institution of Heating and Ventilating Engineers to be held at the Holborn Restaurant (Caledonian Room), on Wednesday, February 9th, at 2.30 p.m., Mr. J. L. Musgrave will give his presidential address, and Miss Margaret Fishenden, D.Sc., will read a paper on the effect of weather conditions upon the heat requirements of a house.

THE annual meeting and dinner of the Cambridge Graduates' Medical Club will be held at the Langham Hotel on Tuesday, March 1st, at 7.15 p.m., with the President, Sir Humphry Rolleston, Bt., K.C.B., in the chair. The honorary secretaries are Mr. Reginald M. Vick and Dr. F. G. Chandler. The price of the dinner (exclusive of wines) is 10s. 6d.

THE anniversary dinner of the Medical Society of London will be held at the Grand Hotel, Trafalgar Square, on Monday, March 7th, at 7.30 p.m.

DR. WANKLYN will lecture for the Fellowship of Medicine on the exanthemata, with special reference to small-pox, on February 10th, at 5 p.m., at the Medical Society, 11, Chandos Street, W.1, and Mr. Trethowan will give a demonstration at the Royal National Orthopaedic Hospital on the same day at 3 o'clock. A lecture on the causes and treatment of vomiting in children will be delivered by Dr. Beatty at the Royal Northern Hospital on February 15th at 3.15. These lectures and demonstrations are open to medical practitioners without fee. Beginning on February 7th the Paddington Green Hospital and the Victoria Hospital will hold jointly a two weeks' course in diseases of children; on the same date, at the London Lock Hospital, a four weeks' course in venereal diseases will open. The Royal Northern Hospital is arranging a special course, free to medical practitioners, for one week from February 21st. The Fellowship arranges practical courses in anaesthetics and courses in obstetrics; arrangements are made for clinical assistantships. Copies of all syllabuses of special courses, the general course programme, and the *Post-Graduate Medical Journal*, are obtainable from the Secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1.

THE next meeting of the Post-Graduate Hostel will take place at the Imperial Hotel, Russell Square, W.C.1., on February 7th, at 9 p.m., when Mr. Clifford Morson will discuss prostatic disease. On February 10th Dr. R. M. Brontë will give an address on the medical witness in relation to crime. All medical practitioners are welcome to the meetings. Dinner (5s.) at 8 p.m.

THE Central London Ophthalmic Hospital has arranged for a clinical demonstration to be held by members of the staff on the first Tuesday of each month at 5 p.m. Practitioners and students of medicine will be admitted without fee. Those proposing to attend are asked to notify the Secretary at the Hospital, Judd Street, W.C.1.

A SHORT course of lectures on functional nerve disorder, for medical practitioners and students, will be given at the Tavistock Clinic for Functional Nerve Cases, 51, Tavistock Square, W.C.1, between February 14th and 25th. The lecturers are Drs. W. Langdon Brown, James Young, J. R. Rees, S. Roodhouse Gloyne, and H. Crichton Miller. The fee for the course to practitioners is £2 2s., and to medical students 10s. 6d.

THE new Post Certificate School of the General Lying-in Hospital, York Road, London, will be opened by the Right Hon. Neville Chamberlain, M.P., Minister of Health, on Tuesday, February 8th, at 3.15 p.m. The presentation of the building will be made to Sir Francis Champneys, Bt., M.D. (president of the hospital), by Mr. H. W. Lydall, the donor's solicitor. The chair is to be taken by Dr. John S. Fairbairn, and the ceremony will be followed by a reception.

THE Grocers' Company announces in our advertisement columns scholarships with the object of encouraging original research in sanitary science. The scholarships are tenable for one year, but renewable, and are of the value of £300 a year each, with an allowance to meet the cost of apparatus and other expenses in connexion with the work. The next election takes place in May, 1927. Forms of application and further particulars may be obtained from the Clerk of the Grocers' Company, Grocers' Hall, London, E.C.2.

WE are informed that a questionary has been issued to a number of medical practitioners in England, Scotland, and Wales by the National Association of British and Irish Millers in order to ascertain the views of the medical profession on white bread. An accompanying letter explains that the association is desirous of obtaining representative and authoritative medical opinion on the value of the type of bread which has been evolved by the public requirements of many years, and for the making of which nearly all its mills are specially equipped. Each doctor is asked whether he concurs in the statement that "the curse of our age is that we are provided with white bread"; whether he considers that, having regard to the average variety of diet now enjoyed by people in this country, white bread is a good and nutritious food; whether he considers that white bread, as part of an ordinary mixed diet, is likely to lower the standard of health; and whether he personally eats white bread. We are informed that the identity of those furnishing replies will be treated as confidential, and that the names were selected to cover every county, but otherwise were picked at random from the *Medical Directory*.

AT a meeting of some twenty medical men from various British spas, held in London on January 21st under the chairmanship of Dr. Kerr Pringle of Harrogate, it was resolved to establish a spa practitioners' association. Membership is open to registered medical men and women practising at a British spa. The annual subscription is 10s. 6d. The secretary is Dr. J. B. Burt, 11, Broad Walk, Buxton, from whom all particulars can be obtained.

THE Central Association for Mental Welfare is arranging, with the approval of the Board of Education, a ten weeks' course of instruction from May 2nd to July 9th, 1927, for teachers of mentally defective and of dull and backward children. Lectures will be given in London on normal and abnormal psychology, methods of teaching, the medical aspects of mental deficiency, and social and legal work for defectives. Previous courses of this kind were held in 1925 and 1926. Further information may be obtained from the Central Association for Mental Welfare, 24, Buckingham Palace Road, S.W.1.

A REPORT on the school of midwifery and gynaecology in the University of Hong-Kong was issued by Professor R. E. Tottenham in *The Caduceus* for November, 1926. The work of the maternity department in the Government Civil Hospital during the year ending April 20th, 1926, is described, and reference is made to the apparent rarity of contracted pelvis in Chinese women. A clinical report of the gynaecological departments of the Government Civil and the Tsan Yeuk Hospitals is also given, and an interim report on gynaecological specimens in the school of pathology of the University.

THE gold medal of the Carnegie Hero Fund has been awarded to the surgeon and radiologist Dr. Honoré Vercauteren of Ghent, who has had several fingers amputated for radiodermatitis.

PROFESSOR H. F. O. HABERLAND of the Augusta Hospital, Cologne, who is compiling an extensive monograph on blood transfusion, asks for reprints of recent articles or records of unpublished cases, especially failures.

A BILL for making antityphoid inoculation compulsory has been laid before the French Senate.

DR. DAVID DUFF of Gray's Inn has been called to the Bar.

LIEUT.-GENERAL SIR JOHN GOODWIN, K.C.B., who was Director-General of the Army Medical Service from 1918 to 1923, has been appointed Governor of Queensland. Sir John Goodwin rendered distinguished service during the war. He holds the Mons star and the Allied and Victory medals, and received the C.M.G. in 1915 and the C.B. in 1918. He went with Mr. Balfour's mission to the United States in 1917 and was very successful in explaining to the American medical profession the position in which we were at that time; he received the American distinguished service medal and decorations from France, Belgium, and Italy. Earlier in his career he served with several expeditionary forces on the Indian frontier. Since his retirement he has been acting as Organizing Adviser of the British Empire Cancer Campaign.

A BEQUEST of 25,000 dols. (£5,000) for the establishment of a free dental clinic at Musselburgh has been made by Mr. Julius Brown, who died at Santa Monica, near Los Angeles, California, on December 9th last. Mr. Brown was a native of Musselburgh.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the BRITISH MEDICAL JOURNAL must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the JOURNAL, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the BRITISH MEDICAL JOURNAL are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:
EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology Westcent, London.*
FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*
MEDICAL SECRETARY, *Mediocra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

QUERIES AND ANSWERS.

DR. H. G. BURFORD (London, W.1), who has heard that varix has been treated successfully in Vienna by a solution of grape sugar, wishes to know whether the method has been tried in this country, and with what results.

POST-INFLUENZAL COUGH.

IN our issue of January 15th (p. 124) "W. H. F." asked for suggestions for the treatment of persistent cough following acute influenza which had resisted all sedatives. The following suggestion has been received in reply from "M. R. S.": Benzyl benzoate, 2 to 8 minims, as an emulsion or in capsules, acts almost "like a charm," especially for those paroxysms which occur in the early hours of the morning. As the patient gains strength the tendency to these "attacks" is lessened and finally disappears.

IODINE TREATMENT OF RHEUMATOID ARTHRITIS.

DR. A. E. COLLIE (Newport, I.W.) writes in answer to "M.B." (January 15th, p. 124): The following two cases at present under my care may be of interest. Mr. A., aged 73, has had rheumatoid arthritis for several years and has been unable, owing to pain and stiffness of his joints, either to dress or feed himself without assistance. Miss B., aged 44, has been crippled by rheumatoid arthritis for the past ten or twelve years. There is much deformity of the hands and toes, and she suffers considerable pain in the limbs. For the past three months both patients have been taking 20 minims of syrup of iodide of iron in water night and morning, together with 1 drachm of Crookes's collosol iodine three times a day after food. After the first dose or two of the collosol iodine, Mr. A. complained of sickness. I therefore combined the drug with 20 minims of liquid extract of liquorice and half an ounce of chloroform water, and this combination eliminated the nausea and vomiting. After two months of this treatment Mr. A. was able to dress himself alone and lace his own boots. He can now walk over half a mile, which he has not been able to do for the past three years. In the case of Miss B. the results are not so striking, but the treatment has certainly improved her condition and the pain is not so severe.

INCOME TAX.

"E. R. B." is working as an assistant and uses a two-seater car averaging 100 miles a week. He has been allowed a sum of £5 per annum only for expenses as compared with his employer's allowance of £350 for two cars. What should he claim?

*** It has to be remembered that the rules for allowances to employees fall under Schedule E and are more restrictive than those under Schedule D—for example, there is no allowance for depreciation as such, though presumably the cost of renewals can be claimed for when necessarily incurred. We advise "E. R. B." to claim the amount of his actual running expenses for the year (revising his claim when the year expires if necessary), but excluding any expenses incurred in the private use of the car, and to intimate in doing so that he intends to lodge a supplementary claim for replacement of the car for the year in which that expenditure is incurred.

LETTERS, NOTES, ETC.

ACQUIRED MELANISM IN MOTHS TRANSMITTED BY INHERITANCE.

MELANISM is a subject which attracts increasing interest in biology as well as medicine, and in the issue of *Nature* (January 22nd, p. 127) Dr. J. W. Heslop Harrison has published an interesting account of acquired melanism occurring in certain moths in districts which have become industrialized. On Tyneside twenty-five years ago the moth Mottled Beauty corresponded with its name; now every specimen captured has become black. The same has been observed to occur in other species, such as the Pale Brindled Beauty and the Engrailed. On the Continent similar instances of the development of melanism, affecting the Poplar Lutestring, and the Great Oak Beauty, have been noted in districts which have become the seat of industry. The Peppered Moth has gone black both in England and in America (at Pittsburg), as also the Small Engrailed. As large amounts of manganese have been found in the foliage of trees upon which the larvae feed in Middlesbrough Park, larvae were fed on foliage contaminated by manganese, also by lead, and breeding yielded melanized individuals. The larvae of these in turn were fed on uncontaminated food, but the acquired melanism was transmitted to its descendants. Thus acquired melanism was proved to be transmissible by inheritance.

WOMEN ON HOSPITAL STAFFS.

WE continue to receive letters commenting on a statement made in our issue of November 6th that we believed that the election of Miss Lily Baker, B.A., M.B., to the staff of the Bristol Royal Infirmary created an important precedent, implying that a woman had not previously been appointed to full membership of the honorary medical staff of a general hospital with a teaching school. In a later issue we qualified this statement by excepting the Royal Free Hospital; and we are reminded by Miss May Thorne that at this hospital the Committee of Management appointed a woman on its staff as honorary gynaecologist in 1902. Since then, of course, a number of appointments of women have been made at the Royal Free Hospital. Miss Marion B. Andrews points out that at the Ulster Hospital for Children and Women at Belfast, a teaching hospital in connexion with the Queen's University, she was appointed assistant surgeon in 1904, full surgeon in 1906, and consulting surgeon in 1917.

APROPOS of a previous reference to appointments at children's hospitals Dr. C. BUTTAR writes that, as a mere man, he objects to the assumption that a children's hospital, even if used for teaching, can be described as a general hospital. It is true, he says, that the word "special" is used of hospitals in two senses, either of special diseases or of a special class of patient; but a general hospital, surely, is a place where any persons (including men) can be attended for any disease.

AN ALTERNATIVE TO CIRCUMCISION.

DR. I. M. JEFFERISS (Lakenheath) writes: The description of the simple procedure required in the treatment of cases of phimosis by the late Dr. D. W. Whitfield (January 29th, p. 187) should be hung up in every hospital out-patient department. To circumcise a normal boy is a barbarous and unnecessary operation. Circumcision is only required when retraction of the prepuce is impossible owing to scar tissue or other results of balanitis. A protective covering to the glans penis is not an abnormal condition, and apart from the performance of the operation as a religious rite there is no need to cut off a portion of the human body for the sake of cleanliness. Every prepuce unaffected by pathological conditions can be retracted by the aid of a blunt probe and a little patience. Recurrent herpes of the glans has been treated by me by fixing a permanently retracted prepuce over the glans with lint and strapping until the organ regained its natural protective covering. There is no need to stretch the prepuce and no more need to remove it than there is to remove the average visible and properly developed tonsil.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 42, 43, 46, and 47 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 44 and 45.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 47.

An Address on DISSEMINATED SCLEROSIS:

With Special Reference to its Infective Origin.*

BY

DOUGLAS McALPINE, M.D., M.R.C.P.,

PHYSICIAN IN CHARGE, DEPARTMENT OF NERVOUS DISEASES, MIDDLESEX HOSPITAL; ASSISTANT PHYSICIAN AND PATHOLOGIST, HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE, LONDON.

THE study of nervous diseases is always considered to be an interesting but depressing occupation, because so little can be done for the patient. This, unfortunately, applies to the majority of organic nervous diseases. Before the discovery of the important part which the *Spirochaeta pallida* plays in the production of disease of the central nervous system, the outlook, as far as therapeutic measures went, was certainly much poorer than it is to-day. Of late years much knowledge has accumulated regarding the physiology and pathology of the nervous system, but less attention has been paid to the etiology of a number of obscure diseases. Certain links in the chain connecting pernicious anaemia and subacute combined degeneration of the cord have, it is true, been filled in, especially the recognition of achlorhydria as a constant feature of this syndrome and the importance of a megalocytosis as being often the only abnormality in the blood picture during the remissions of the disease. The next gap has yet to be crossed, and it will only be achieved by the aid of bacteriology.

The symptomatology of disseminated sclerosis and its pathological basis have been described in scores of papers in this and other countries during the past twenty years, but knowledge of the underlying cause is still wanting. This can, I think, be attributed to the lack of co-operation between the neurologist and the bacteriologist. The position as regards disseminated sclerosis is much the same as that which existed in respect to syphilis prior to the discovery of the Wassermann reaction and the *Spirochaeta pallida*.

DISSEMINATED SCLEROSIS AS AN INFECTIVE DISEASE OF THE CENTRAL NERVOUS SYSTEM.

Under this heading we may consider briefly the reasons why disseminated sclerosis is considered to have an infective origin.

1. *Clinical.*

From the clinical aspect it is well known that so-called "*influenzal*" attacks may usher in the disease or accompany relapses during the course of the disease. These attacks consist of headache, general malaise, and usually slight pyrexia. It seems probable that such attacks are not "*influenzal*," but result from the circulation within the blood of the organism or toxin of disseminated sclerosis. Again, fever is not uncommon during the course of the disease, especially in early cases and during relapses. This question has recently been studied by Epstein[1] in 34 cases. In 22 of these fever was present at some time during their stay in hospital, but the temperature rarely exceeded 100° F. Further clinical evidence is afforded by the characteristic relapses and remissions which occur during the course of the disease in the majority of cases. Any theory which attributes the condition to developmental errors falls to the ground in the presence of the curious variations in the clinical picture. In this respect disseminated sclerosis resembles meningo-vascular syphilis, pulmonary tuberculosis, and other chronic infections. The variations in the intensity of the infective process can be best explained by supposing that a virus, or its toxin, periodically invades the central nervous system, so producing a train of symptoms which will depend on the particular part of the neuro-axis attacked.

2. *Serological Evidence.*

A study of the cerebro-spinal fluid in disseminated sclerosis shows that, frequently, certain changes occur in the fluid which could only result from an active infective process in the central nervous system. The usual findings in the cerebro-spinal fluid are as follows: The Wassermann reaction is always negative; there is little or no increase in the percentage of albumin or in the number of cells. The various tests with colloidal substances, such as gold and benzoin, show a positive curve in about half the cases. The colloidal gold reaction, owing to want of standardization by the majority of workers, has not attained the important place in the diagnosis of this disease it should have. In France the colloidal gold has been supplanted largely by the colloidal benzoin reaction, which is certainly easier and would seem to give more stabilized results.

3. *Pathological Evidence.*

The pathological evidence as to the infective nature of disseminated sclerosis cannot be set out in the time at my disposal. I will merely quote the opinion of J. W. Dawson,[3] whose work, published in 1916, forms an exhaustive treatise on this part of the subject.

> "The process underlying disseminated sclerosis is a subacute disseminated encephalo-myelitis, which terminates in disseminated areas of actual and complete sclerosis." And again he writes: "It is concluded, therefore, that there is much to favour the view that disseminated sclerosis is due to a specific morbid agent which calls forth a clearly defined clinical and anatomical picture." And later he adds: "The causal agent is, therefore, probably of the nature of a soluble toxin and it is conveyed to the nervous tissues probably by the blood channel."

4. *Experimental Evidence.*

The experimental evidence, as is usual in such a disease as we are dealing with, is both positive and negative. Positive evidence in the hands of careful observers must outweigh the negative findings of others. Bulloch[2] (now Gye) in 1913 injected into a rabbit some of the cerebro-spinal fluid from an acute case of disseminated sclerosis in a young man of 19. The injection was made in the region of the sciatic nerve. On the thirteenth day the animal showed paralysis of the hind limbs. Three days later all four limbs were paralysed and there was incontinence of urine. The animal was then killed. Intense congestion and oedema of the grey matter in the cord was found, whilst in different situations the myelin sheaths were broken up. In another experiment, using the cerebro-spinal fluid from the same patient, he was able to produce transitory paresis in the hind limbs of a rabbit, after filtering the fluid. Bulloch concluded from these experiments that he was dealing with a filterable virus. Kuhn and Steiner,[4] in 1917, in a large series of experiments conducted on rabbits and guinea-pigs, were able to produce paresis in the limbs in two-thirds of the animals. It is interesting to note that those animals which were inoculated only with cerebro-spinal fluid were unaffected. The positive results were obtained when blood from the patients was used. Several other workers in Germany and France have obtained similar results. More recently Adams, Blacklock, and Macluskie[5] have worked on this subject in Glasgow. They inoculated cerebro-spinal fluid from several cases of disseminated sclerosis into sixteen rabbits. Five of the animals showed nervous symptoms, either in the form of paralysis of the legs or of typical cerebellar symptoms. On using citrated blood for inoculation, nervous symptoms appeared in five out of eleven animals. In several instances they were able to produce symptoms in rabbits after inoculation with an emulsion of the central nervous system of another rabbit which had been successfully inoculated with cerebro-spinal fluid from a patient. As I have said, other workers have carried out similar experiments with negative results, but on the whole there seems to be sufficient experimental proof of the infective nature of the disease.

THE NATURE OF THE INFECTION.

Farquhar Buzzard[6] in 1911 suggested for the first time that the disease might be due to a spirochaete. Kuhn and Steiner, during the experiments already mentioned, demonstrated spirochaetes in the heart's blood and in the vessels

* Given before the Oxford Division of the British Medical Association.

of the liver of the animals. Siemerling[7] observed in the brain of a man, who had died from disseminated sclerosis, living spirochaetes under dark-ground illumination. One or two others have reported similar positive results at autopsy, but none of these spirochaetes could be stained by the usual silver methods. Adams and his fellow workers found spirochaetes in various internal organs of their inoculated animals. Other evidence, positive and negative, I have not time to discuss. The spirochaetal theory of disseminated sclerosis at present rests on insufficient evidence and must be considered to be not proven. Three difficulties lie in the way: (1) the fact that spirochaetes of various sorts normally are present in most animals used for experimental purposes; (2) it has not been found possible to obtain a growth of the spirochaetes so far found by various observers; (3) if the disease be spirochaetal in origin, then the difficulties are increased by the probability that we are dealing with a class of organism that has a life cycle, and its other forms may be overlooked since we are unable to recognize them.

THE MODE OF INFECTION.

1. *Endogenous Theory.*

Before passing on to the more solid ground of the clinical aspect of the disease let us consider the possible methods of infection in disseminated sclerosis. Is the disease due to some endogenous cause—that is to say, is the virus present in the mouth or gastro-intestinal tract of normal individuals, and under certain conditions and in certain persons becomes pathogenic? We have numerous analogies—the pneumococcus, streptococcus, *Bacillus coli*, etc. Spirochaetes of various kinds—if a spirochaete be the cause of the disease—can be isolated from the mouths of most of us, and are present in the intestine in quite a large proportion of normal persons. It is possible that under certain conditions they may become pathogenic.

2. *Exogenous Theory.*

Another aspect of the disease, for knowledge of which I am indebted to Dr. D. K. Adams of Glasgow, must be considered. He has noted the relative high proportion of agricultural workers and woodworkers among the sufferers from disseminated sclerosis. He has also found that not infrequently the father of the patient follows one of these two occupations. The fact that the disease appears frequently in healthy young adults has suggested to Adams[8] that the cause of the disease is an accidental infection. In Germany this exogenous theory of disseminated sclerosis has been studied by several observers. In a personal communication Professor Kuhn says that Steiner first advanced the theory of an external infective agent. Steiner[9 10] points out in a recent paper that the disease is unknown in China and Japan; it is very rare in South America, and rare in Italy. It is most common in Switzerland, and this statement is borne out by some figures in a recent paper by Bing and Reese,[11] who found that disseminated sclerosis in Switzerland occurs twice as frequently as does tabes dorsalis. The disease is also common in Germany, France, and Great Britain. Steiner believes that the explanation of the difference in the regional distribution of the disease may be found in the mode of life or occupation, or in the distribution of carriers of infection, possibly insects. With regard to the occupational incidence of the disease, Steiner attaches considerable importance to the work of Dreyfus[12] on this point. Dreyfus, in 1920, collected records of 1,151 cases of disseminated sclerosis which had been reported or personally observed in recent years in Germany; 672 of these were males and 479 females. He found an absolute preponderance of the disease in agricultural workers and in woodworkers. For instance, according to census figures, in Germany there were 25 carpenters per 1,000 male population. Dreyfus found the incidence of disseminated sclerosis in carpenters to be 32 per 1,000—that is, an excess of 7.8 per 1.000 over the census figures. The woodworkers of all kinds with the disease showed an excess of 18 per 1.000 over the census figures. Dreyfus adds that the number of cases investigated is relatively small, and consequently the probable error is relatively large. Steiner studied the question of occupation in 500 army pensioners, and found that woodworkers showed a preponderance, which was also apparent in the father's occupation. Steiner mentions a striking case of two cousins who frequently spent their holidays together in the same villa, to which a garden was attached. Both the cousins contracted the disease, as did the gardener.

I have so far investigated the various points mentioned above in only 110 cases of disseminated sclerosis. This number is, of course, much too small to permit any conclusions to be drawn at the present moment, but enough positive evidence has been obtained to suggest that an accidental infection may be the cause of the disease in some cases, and that further investigation in this direction is desirable.

It seems probable that there is a latent period, which may cover several years, between the actual infection and the appearance of signs denoting involvement of the central nervous system. Therefore, in studying the history of a case, it is necessary to inquire into the circumstances of the patient's life over a long period, stretching back, in some instances, to childhood.

From the point of view of an infective agent it seems difficult to bring into line the tendency of agricultural workers and woodworkers to the disease. There is little evidence that only those working with diseased woods are attacked; on the contrary, it would seem that the highest incidence occurs in those who work with prepared wood.

Some of those who are engaged in general practice may have an opportunity of investigating this aspect of the disease, and I would suggest that a careful inquiry into the various circumstances of the patient's life prior to the onset should be made. Particular attention should be paid to the places of residence (town, country, or farm), occupation, hobbies (especially with regard to woodwork), and the father's occupation. It is possible that in this way fresh light may be shed on the problem of the causation of this common and crippling disease.

CEREBRAL FORMS.

The varying clinical pictures of disseminated sclerosis are well known. In the majority of cases its symptomatology depends on changes in the brain stem and spinal cord. These two parts of the neuro-axis may be attacked simultaneously, but quite frequently either one or the other may bear the first brunt of the disease. I shall not dwell on the common spinal cord types, but will say a word about the various symptoms which may be produced by invasion of the brain itself. I wish to make it clear, however, that the infective process, even at an early stage, is usually much more widespread than would appear from the clinical picture, and that even when this points solely to involvement of the cord, in the majority of cases the disease has already invaded the brain and in particular the margins of the ventricular cavities. Keeping this idea of the true dissemination of the disease before us, let us consider the effect of the disease on the cerebral tissues from a clinical standpoint. At an early stage three symptoms may appear, either together or independently. The first is headache, the second giddiness, and the third either diplopia or blindness. The headache is usually generalized and may be severe. It is frequently aggravated by anything which temporarily increases the intracranial tension, such as coughing, sneezing, and stooping. It is intermittent, lasting for one or several days at a time, and sometimes accompanies a clinical relapse; not infrequently it is attended by vomiting. The type of headache recalls that observed in conditions in which there is a rise in the tension of the cerebro-spinal fluid. It may either be toxic in origin or, as I am inclined to believe, is dependent on a temporary hydrocephalus. Whatever the explanation may be, this symptom is a common witness of the invasion of the cerebrum.

Hemiplegic Type.

There are a few types of cerebral disseminated sclerosis which must be mentioned. First the hemiplegic. This is somewhat rare, but probably not so rare as has been imagined. We must all have met with puzzling cases

of sudden hemiplegia in healthy young or comparatively young persons. Such attacks may be indistinguishable from an apoplectiform seizure; usually there is no loss of consciousness. We examine the heart and find nothing abnormal. The urine and blood pressure are normal. We plump then for syphilis and are rebuffed by a negative Wassermann reaction. By this time our thoughts have turned to the possibility of haemorrhage into a cerebral tumour, and while we are ruminating over this, the power begins to return, and within a couple of weeks or so the hemiplegia has passed off. Such cases are often labelled "cerebral thrombosis of unknown cause." The true explanation is usually disseminated sclerosis, which has begun by attacking the region of the internal capsule. I will relate two such cases.

CASE I.

A man, aged 38, had lived on a farm since childhood. His father was a farmer. At the onset of the disease he was working as an estate carpenter. He enjoyed good health until March 20th, 1924, when he experienced a stiff feeling in the right hand which grew rapidly worse within the next few hours. The following morning he was paralysed in his right arm and leg; he was admitted to the Middlesex Hospital, where he was found to be suffering from an organic right-sided hemiplegia. The condition quickly improved and by the end of two weeks he was allowed up. A few days later, however, he had an attack in which his right arm and leg became drawn up, numb, and powerless. At the same time he had a severe headache, lost his speech, and became blind in the left eye. Diplopia was noticed about the same time. The Wassermann reaction was negative, both in the blood and in the cerebro-spinal fluid, which was normal. Unfortunately the colloidal gold reaction was not tested. I saw him for the first time within a week of this attack. The physical signs consisted of nystagmus, pallor of the temporal half of the left disc, and moderately severe right-sided hemiplegia. He again quickly improved. Within the next few months he had further slight "strokes," two affecting the right side and one the left. He was admitted under my care into the Hospital for Epilepsy and Paralysis, Maida Vale, in May, 1925. He showed a marked degree of euphoria and a tendency to involuntary laughter. Nystagmus was not present. There was about 50 per cent. loss of power in the limbs on the right side and the right plantar response was extensor in type. The power on the left side was within 10 per cent. of normal. The left plantar response was flexor in type. No sensory loss, tremor, or ataxia was apparent. The tonsils, which were septic, were removed. He was treated by typhoid vaccine and with arsenic by the mouth. He improved greatly. Subsequently he had several courses of bismuth given by intramuscular injection. During the recent strike he drove a motor bus every day for two weeks and neglected treatment. Within the last month he has had a further hemiplegic seizure.

CASE II.

A woman, aged 25, became ill first at the age of 17, six weeks after running accidentally into a signpost. She began to have severe headaches, accompanied by vomiting and followed by diplopia. About a fortnight later she noticed loss of power in the right arm, and experienced great pain in this limb. A few days afterwards she became unconscious, and remained semi-comatose for several days. She was seen by Dr. Campbell Thomson, who suspected a cerebral tumour, and ordered her removal to Maida Vale Hospital. There she was found to have moderately severe right-sided organic hemiplegia with hemianaesthesia and paresis of the left external rectus. The speech was hesitating, but there was no aphasia. The discs were normal. She improved rapidly after the first few days in hospital, and was discharged five weeks later, with no headaches and almost normal power in the right arm and leg. For some months after she was subject to headaches, especially on excitement, but these then disappeared. The paresis of the limbs entirely passed off. Since then she has remained well except for occasional attacks of pain, which she describes as a throbbing, wrenching sensation in the right arm; this pain usually lasts a few minutes. At the beginning of April, 1925, the finger-tips of the right hand suddenly became dead, and she was unable to hold a pen properly. A few days later an agonizing pain, similar to that described above, was felt in the right arm, and the hand and forearm showed involuntary movements. Within the next week or so she had three attacks of convulsions in the night, which from her mother's description appear to have been epileptiform. She was admitted to Maida Vale Hospital in June, 1925, for observation, but at that time all symptoms had disappeared. The pupils and cranial nerves were normal. There was no nystagmus, and the discs appeared normal. There was no change in her mental outlook. There was no loss of power or sensation in the right arm; no ataxia or tremor was observed. The deep reflexes in the arms were brisk and equal. The abdominal reflexes could not be obtained on the right side, and were sluggish on the left. There was no paresis or alteration in the reflexes in the lower limbs. The Wassermann reaction of the blood was negative. The cerebro-spinal fluid was normal, including the colloidal gold and the colloidal benzoin curves. She has been treated with liquor arsenicalis, stovarsol, mercury, and iodides, and has remained in fairly good health. In this case the disease seems more or less localized clinically to the region of the left internal capsule and left thalamus.

Such cases as these are often difficult to diagnose in the early stages, and may closely resemble a cerebral tumour, especially that type in which the tumour, usually a glioma, first makes known its presence by the occurrence of a haemorrhage into its substance.

Before leaving this hemiplegic type I must mention that an epileptiform seizure may be the first symptom of the disease, and sometimes is associated with hemiplegia, as in Case II. Unless, of course, other signs, such as hemiplegia, accompany the fit, such attacks are indistinguishable from ordinary epilepsy. They may at times be Jacksonian in type.

Ocular Symptoms.

Diplopia is so well recognized as a frequent early symptom of disseminated sclerosis that it need not detain us. The other important ocular symptom which may bring the patient under care is sudden blindness, usually unilateral. Headache is frequently present for the day or two preceding the failure of vision; pain is usually felt behind the eyeball. The sight fails rapidly, so that within forty-eight hours little vision remains. The central vision is chiefly affected. The pupil is dilated, and reacts somewhat sluggishly to light. On ophthalmoscopic examination the disc frequently appears normal. Should the "patch" be close up to the optic nerve head, then a moderate degree of swelling of the disc with blurring of its edges may be observed. In the great majority of these cases no septic focus, such as suppuration in the nasal sinuses, can be discovered, and it is now generally held that disseminated sclerosis is the explanation of this blindness, by virtue of a "patch" somewhere along the optic nerve. The blindness clears up more or less completely within a few weeks, but other signs of disseminated sclerosis make their appearance sooner or later. Pallor of the temporal half of one or both discs is extremely common in cases of disseminated sclerosis even when there is no history of a retrobulbar neuritis.

Why should the optic nerve be picked out in this disease? There are three possible answers to this question. (1) That the infective agent is present in the posterior ethmoidal or sphenoidal cells and gains access to the optic nerve by penetrating the very thin barrier which separates these structures. (2) The subarachnoid space is continued out along the optic nerve to within a short distance of the eyeball. Certain other cranial nerves, the fifth, seventh, and eighth, also possess this prolongation of the subarachnoid space, but in the case of the optic nerve it is wider than in the others. If the virus of disseminated sclerosis be present in the cerebro-spinal fluid, then in view of these facts it is the optic nerve, bathed by the spinal fluid throughout its course, which would be most vulnerable. (3) Lastly, the possibility of a selective action of the virus on this particular nerve has to be considered. Personally, I think that one of the first two explanations lies nearest the truth.

Alterations in the Mentality of Patients Suffering from Disseminated Sclerosis.

That mental changes may occur in some cases during the course of the disease has long been recognized. These changes have been divided into those denoting interference with the highest cortical processes resulting in varying degrees of dementia, and those characterized by alterations in mood, such as increased cheerfulness or euphoria. Under the second heading are usually grouped those cases which show pathological laughter or crying. Dementia is rare in disseminated sclerosis, and is directly dependent on the invasion of the subcortical white matter by the disease. The following case is instructive from this point of view, as well as by the rapid course of the disease.

CASE III.

A woman, aged 46 (a trained nurse), one day during December, 1924, fell suddenly and was unable to get up. It is uncertain whether she lost consciousness or not. She was admitted to the National Hospital, Queen Square, where the diagnosis was "right-sided hemiplegia ? disseminated sclerosis." The cerebro-spinal fluid gave a negative Wassermann reaction, 10 cells per cubic millimetre, 0.04 per cent. albumin, and a well marked Lange gold curve. She improved slightly and was discharged three

months later. In May, 1925, she had a relapse, during which the paresis on the right side became more evident. Shortly afterwards marked tremor of the right arm made its appearance. During 1925 a great change was noticed in her mentality. She came under my care in Maida Vale Hospital in December, 1925, when the most striking point was the intense mental deterioration which had evidently taken place. She seemed to have great difficulty in understanding what was said to her, and answered questions in a slow, disjointed fashion. She had very hazy notions as to the duration of her illness, and as to how long she had been in hospital or the name of the hospital. She seemed quite unable to fix her attention on anything for more than a few seconds. She was markedly emotional, and would laugh or cry at the slightest provocation. It was impossible to ascertain whether her outlook on life was cheerful or the reverse. Her mental condition could be summed up as moderately severe dementia. There was no nystagmus, and the discs appeared normal. The speech was markedly dysarthric. There were signs of a right-sided hemiplegia, and a tremor of great range and amplitude affected the right upper limb. It was present at rest, and therefore did not conform with the usual intention tremor of disseminated sclerosis. In view of the age of the patient, the absence of papilloedema, and the negative Wassermann reaction in the cerebro-spinal fluid with other positive findings in the fluid, a diagnosis of disseminated sclerosis was made, chiefly involving the cortex. The case was too advanced for treatment to be of any avail. She gradually became worse, and died on January 19th, 1926, fourteen months after the onset of the disease. At autopsy the brain was found to be riddled with patches of disseminated sclerosis, especially the subcortical white matter and the periventricular margins.

Much more common are the alterations in mood. A recent and very instructive paper by Cottrell and Kinnier Wilson[13] deals with this subject. In 100 unselected cases they investigated the psychological outlook on life before and after the onset of the disease. They classify their results under three headings: (1) change in mood, (2) change in bodily feeling, (3) change in emotional expression and control. A change in mood they found to be present in every case they investigated. In 63 per cent. of the cases this change was in the direction of cheerfulness or happiness, to which they apply the term "euphoria." A change in bodily feeling, which they distinguish from a change in mental outlook and to which they give the name "eutonia," was present in 84 per cent. of the cases; in the remaining cases the change was either one of physical ill-being or a combination of this with a sense of well-being. Changes in emotional expression and control were also pronounced features in their series of cases. In 90 per cent. of the cases smiling and laughing were obvious features and appeared without adequate stimuli. In only two cases were they able to demonstrate actual intellectual deterioration. Cottrell and Wilson believe that these changes occur even in the early stages of the disease and are of importance in diagnosis. In their own words,

> "No single symptom of the neurological series (nystagmus, tremor, scanning speech, paraesthesiae, spasticity, amaurosis, etc.) occurs with anything like the same frequency in an unselected century of cases of the disease, and that the cardinal symptoms are not neurological in its limited sense but belong to the emotional, affective and visceral spheres."

These observations are of great interest, and will repay close study. If a young adult whilst telling you of a weakness in an arm or a leg seems extraordinarily cheerful about the whole affair, then suspect disseminated sclerosis, and do not put off the diagnosis if none of the classical signs of the disease are present.

Cerebellar Type (so-called).

It is well recognized that the first sign of the disease may be ataxia. The usual history of such a case is as follows. A previously healthy young adult "catches a cold"; some days later he sees double, is troubled with headache, and may vomit. Later, on attempting to get out of bed, he feels giddy and unsteady on his legs; the giddiness may be marked even when the patient is in bed. On examination nystagmus and ataxia of the upper and lower limbs, usually more marked on one side, are evident. There may be no signs of interference with the pyramidal tracts. Such is the picture of so-called "acute cerebellar ataxia." These symptoms clear up wholly or partially, but eventually relapses occur. The following case conforms to this type.

CASE IV.

A girl, aged 14, was admitted into Maida Vale Hospital in M 1926, under the care of Dr. Anthony Feiling, to whom I indebted for the notes.

Previously a healthy girl, she "caught a cold" on December 3 1925, and was confined to bed for three weeks. During t time she vomited and complained of severe occipital headac She saw double on more than one occasion. On getting out bed at the end of the three weeks it was noticed that she co not walk properly owing to unsteadiness. There was no weakn in her arms and she could sew and knit. After a week or she was able to get about, but was very unsteady in her ga Examination in hospital showed no alteration in mentality; t pupils were equal and reacted normally; the discs were norm and vision was full in each eye. There was a horizon nystagmus on looking to the left. Marked inco-ordination both the upper and lower limbs was present, especially on t left side. There was no loss of power or any evidence of involv ment of the pyramidal tracts except absence of the abdomir reflexes. The Wassermann reaction of the blood was negativ The cerebro-spinal fluid was not examined. There was no histo of otitis media, and examination of her ears was entirely negativ Within the course of the next few weeks she improved so that, discharge, her gait was nearly normal. The fundi remain normal. This girl was sent in with a diagnosis of "? cerebell tumour," but the disappearance of the headaches with improv ment clinically leaves little doubt that it was a case of disseminat sclerosis.

Vertigo is also a common symptom during the cours of disseminated sclerosis, and may be accompanied by hea ache, the patient labelling such attacks "bilious turns."

TREATMENT.

The treatment of a disease such as disseminated sclerosi because of our lack of knowledge of its cause, must necessity be unsatisfactory. Even if the exogenous theor prove to be correct, the problem, so far as treatment concerned, becomes endogenous. The infective agent afte entering the body must find a home. The real problem i to detect its hiding place, from which it or its toxin emerge at intervals to raid the nervous system. Suitabl lairs might exist in the mouth, intestines, or liver. Earl diagnosis of the disease should naturally be aimed at; i would be considerably facilitated if we had at our disposa a complement fixation test comparable with the Wasser mann reaction in syphilis. Until we gain some knowledg as to the causative organism a suitable antigen will only b found as a result of guesswork. The first step in treat ment, having explained the nature of the disease to th patient or a near relative, is to investigate the case fro a general point of view, especially with regard to septi foci. We are told in the treatment of infective arthritis for instance, to search for and treat septic foci; this we do and sometimes we are rewarded by immediate improvement We may attribute the arthritis to this hidden focus—fo instance, an apical abscess—but there is no proof that I an aware of that infective arthritis is actually caused by th organism, probably a streptococcus, isolated from that tooth. And yet removal of the sepsis, probably by once again turning the balance in favour of the patient's resistance, permits of clinical improvement. And so, think, we should regard disseminated sclerosis—namely, a a subacute or chronic infective disease. The mouth should be put in order, and if any doubt exists as to the state of the teeth, then an *x*-ray picture must be taken. I recently had under my care a nurse suffering from this disease, expressed clinically in recurrent attacks of retrobulbar neuritis which had eventually resulted in rather a high grade of optic atrophy. The teeth appeared excellent, but an *x*-ray picture showed apical abscesses in three. These teeth were removed, and the vision in the left eye, previously 6/36, improved to 6/12 within two weeks after the extractions. The right eye remained as before. True, this might be a natural remission of the disease, but as her vision had been very poor for some months it was at least a very happy coincidence. Septic teeth should not be removed wholesale, as on two occasions I have seen a definite exacerbation in the clinical picture result within forty-eight hours. In cases associated with or commencing by blindness, the condition of the nasal sinuses should be investigated.

Careful attention should be paid to the bowels, as constipation is a common symptom, even in the early stages of the disease. In some cases it becomes marked just prior to a relapse.

Medicinal Treatment.

Arsenic has long been recognized as the most useful drug, and the upholders of the spirochaetal theory lay emphasis on this fact. Where possible, early cases should receive precisely the same treatment as that used in neurosyphilis; the dose of intravenous novarsenobillon should, however, never exceed 0.6 gram. Failing intravenous injection, intramuscular preparations of arsenic or bismuth should be given. When such methods are for any reasons impracticable, Fowler's solution should be administered by the mouth, and may be used as a variant to the intravenous and intramuscular methods.

Pyrexial Treatment.

Protein therapy has been tried during the past few years in the treatment of this disease, and some encouraging results have been reported. A mild degree of protein shock may be produced by an injection of milk. It is preferable, however, to obtain a definite rise of temperature, and it has been found that the intravenous injection of typhoid vaccine produced this result. It is usual to commence with a small dose—for instance, 25 million—and gradually increase the amount so that by the end of six or eight injections the patient is receiving 200 millions. Within a few hours of the injection a rigor occurs, and the temperature rapidly rises to 102° or more. During this period there is, of course, general malaise and usually a temporary exacerbation of the symptoms, especially diplopia and spasticity. The injections should be given every fifth day or so, and it is best to give a small dose of novarsenobillon on the day following the injection. This form of treatment should be repeated from time to time. Malaria has also been tried; reports from Vienna are not encouraging in this respect, but Dreyfus and Hanau,[14] in a recent paper, express the opinion that it is more satisfactory than typhoid vaccine treatment. Dr. F. Golla informs me that relapsing fever has replaced malaria at the Maudsley Hospital in the treatment of general paralysis of the insane, and that the results are just as satisfactory as with malaria, and the risk of a fatal termination is considerably less. Relapsing fever might therefore prove more suitable than either malaria or typhoid vaccine as a pyrexial agent in disseminated sclerosis.

It is not easy to say whether any of these various forms of pyrexial treatment are of any real value; the natural mutability of the disease and the comparatively short time that this form of treatment has been on trial have both to be remembered. In a well established case which is more or less stationary I feel sure that no such treatment is of the least use. On the other hand, in a moderately severe case of relatively short duration, in which the disease is obviously active, pyrexial treatment does sometimes appear to bring about a remission. In early cases the chances of arresting the disease, even though temporarily, are greater, and remissions occurring within a short time of the treatment are not uncommon. It may be argued that such remissions are independent of the treatment, and would have taken place in any case. That may be so, but at least such remissions, whatever their cause, *do not* contra-indicate this line of treatment.

In conclusion, it is evident that little advance has been made in the treatment of disseminated sclerosis, and no real progress in this direction can be looked for until we know more of its etiology. The exogenous theory of this disease, though it may seem at first glance to be wild and speculative, is one that may repay further study.

THE PATHOGENESIS OF RESPIRATORY ANOMALIES AFTER EPIDEMIC ENCEPHALITIS.

BY

MACDONALD CRITCHLEY, M.D.BRISTOL, M.R.C.P.LOND.,

LATE RESIDENT MEDICAL OFFICER, NATIONAL HOSPITAL, QUEEN SQUARE, LONDON.

AMONG the many mental and physical after-effects of epidemic encephalitis the respiratory disorders are now recognized as occupying a very definite place. Knowledge of this aspect of the disease has gradually accrued by the publication of numerous isolated case reports.

GROUPING OF CASES.

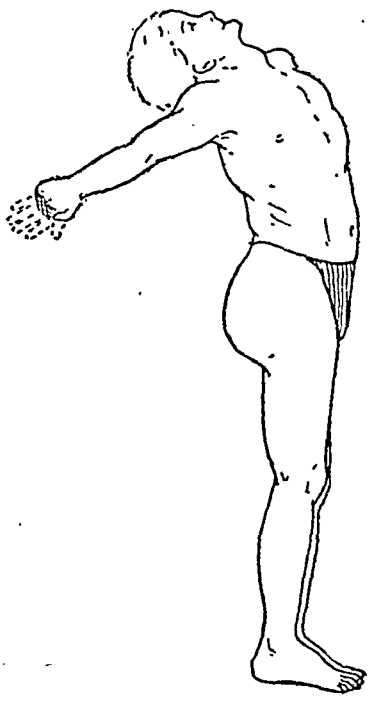
In an earlier paper[1] we pointed out that encephalitic respiratory disorders may occur both in the acute stage and also as "sequelae." The symptoms on analysis may be resolved into three main groups: (1) disorders of the respiratory rate, (2) disorders of the respiratory rhythm, and (3) respiratory "tics." Combinations of these groups often occur, and any of these manifestations may be constant, though more usually they are intermittent.

Respiratory Rate.

The disorders of the respiratory rate comprise acceleration (tachypnoea) and depression (bradypnoea). There is usually no alteration in the pulse rate, no cyanosis, and no thoracic distress in these varieties. In some instances the disorder supervenes only when the patient is supine, in others only when the patient stands upright. In other cases, again, the acceleration in respiration rate only comes on during sleep. The onset is frequently determined by emotional disturbances, such as those occasioned by fright, shyness, or excitement; the attack can often be checked temporarily by a strong effort of will on the patient's part. Again, the attack can frequently be cut short by speaking sharply to the patient or by ordering him to hold his breath, breathe through his nose, or perform some complicated act which will necessitate the patient's close attention. Consciousness is usually retained throughout an attack, but on rare occasions may be lost.

In some instances the lungs become over-oxygenated during the tachypnoeic spells; carbonic acid is washed out of the circulation and the acid-base balance is altered in the direction of a temporary alkalosis. Such a metabolic change results in tetany, of which some half-dozen cases following post-encephalitic tachypnoea are on record.

Bradypnoea is a much rarer manifestation, but may be met with during both the acute and chronic stages. The respiratory rate may fall as low as 6 per minute, and, in order to maintain full oxygenation of the blood, each breath is usually of greater amplitude than normal.



Respiratory Rhythm.

Disorders of the respiratory rhythm comprise those in which there is an irregular spacing in the normal cycle of inspiration : expiration. Such an arrhythmia may be regular or irregular in its metre; it may be paroxysmal or continuous in appearance. The arrhythmia may be apparent during the waking state only, or, conversely, only when sleeping. In other instances it may occur whether the patient is awake or asleep.

Sighing.—This is perhaps the commonest example of a respiratory dysrhythmia, and is often so slight in degree as to escape casual observation. It is especially common in association with Parkinsonism. From time to time the patient takes a deep inspiration followed by a prolonged expiration. A short period of compensatory apnoea usually follows. These sighs occur without any apparent reason at intervals throughout the day or night, often without the patient's knowledge.

Apnoeic Pauses.—Occasionally a patient can be observed to hold his breath in the middle of normal respiration without any preparatory acceleration of rate or depth and without any previous sighing. More commonly the apnoeic pause is ushered in by a series of deep gasping respirat

which may be either slow or rapid in rate. The breath is then held as though voluntarily, in the phase of full inspiration, until the face and neck become suffused and deeply cyanosed. In cases of prolonged inspiratory apnoea consciousness may be temporarily obfuscated and convulsive attacks are not uncommon. In the less severe degrees of this condition the patient performs many grotesque gestures, clenching and unclenching his fists, clawing the air, or twitching. At the end of the apnoeic spells the breath is audibly expelled, and then there follows a shorter period of expiratory apnoea before the resumption of normal breathing.

The drawing reproduced herewith shows a patient suffering from a post-encephalitic respiratory disorder in an actual attack. The patient, a young man aged 25, had been attacked with acute epidemic encephalitis in December, 1924. The respiratory disorder started originally as a persistent dry cough; later the patient developed attacks of breath-holding, occurring many times daily. In the attacks the patient stands up and takes several deep noisy breaths in rapid succession; next he stiffens himself and slowly bends the trunk backwards, at the same time extending the head fully. The arms are raised from the sides to a right angle in an exaggerated "yawning attitude." The forearms are alternately flexed and extended, the hands being maintained in the "accoucheur's attitude" characteristic of tetany. During this time the breath is held in full inspiration; the abdominal muscles are tightly contracted and the veins of the face and neck become extremely engorged. Each spasm is maintained for twenty to thirty seconds; in some instances there is a transient loss of consciousness and the patient falls. The attacks are terminated by a long expiration followed by a short spell of noisy tachypnoea. No physical signs suggesting any degree of Parkinsonism could be discovered. Drawing (from photograph) by Miss D. Pillers, Bristol.

"Cogwheel" Respiration.—A common type of anomaly seen after encephalitis consists in respirations which are jerky and broken in character. The jerkiness is usually more obvious during the expiratory phase. When viewed on a fluoroscopic screen it will be observed that the diaphragm is rising and falling in a series of cogwheel-like movements, and it is probable that this defective diaphragmatic movement is responsible for the peculiar respiration. In cases of the myoclonic variety of encephalitis the diaphragm and other respiratory muscles may participate in the myoclonus, producing a correspondingly jerky character to the respiratory rhythm.

Bigeminal and Trigeminal Respiration.—Analogous to the well known pulsus bigeminus or trigeminus, the respiration rate may take on a regularly alternating character. Thus the breaths may be alternately deep and shallow, or one deep respiration may be followed by two of shallower degree.

Respiratory "Tics."

The varieties of respiratory mannerisms met with in children after epidemic encephalitis are manifold; many of them are usually regarded as instances of "habit spasm." These diverse types may be aggregated and considered under the title of "respiratory tics." They are commonest in children, and may in fact be the only outstanding symptom remaining after encephalitis. More commonly they are associated with psychical and sleep abnormalities, in the absence of gross organic change. Amongst such "tics" one includes the spells of spasmodic cough occurring without any adequate laryngeal, tracheal, or pulmonary abnormality. Another example is found in the "blowing" habits of some post-encephalitics. The patient, usually a child, will suddenly leave off what he was doing, and, inflating the cheeks, give vent to a series of rapid blowing expirations. The child cannot give any adequate reason for his peculiar behaviour. Sniffing constitutes another objectionable post-encephalitic "tic." Expiration of air through the nose—spoken of as *soufflement* by the French—is another similar habit.

Wide gaping of the mouth, occurring from time to time without adequate reason, is commonly observed after encephalitis, especially in association with Parkinsonism. Sometimes the mouth is opened so far as to bring about an actual subluxation of the jaw joints. The patients, on inquiry, state that they have no sensation of fatigue, but that the lower jaw seems to drop of its own accord. They are unable to check the yawning for longer than a few minutes.

GENERAL CONSIDERATIONS.

Many attempts have been made to explain these phenomena; whilst certain observers have been content to dismiss these disorders as hysterical manifestations, the majority of physicians regard them as resulting from definite organic lesions in the central nervous system.

Supporters of the former conception stress the diversity of the clinical manifestations, their inconstancy, and the theatrical and bizarre nature of the accompanying gestures. They emphasize the emotional instability of many of the patients, and their susceptibility to environmental factors. The precipitation of the attack under psychical stress, its aggravation by excitement, and lastly its frequently abrupt arrest by strong suggestion, are also quoted. The similarity of the respiratory "tics" to the well recognized habit spasms of childhood is another argument. They point out, too, that similar respiratory anomalies—tachypnoea, periodic apnoea, Cheyne-Stokes breathing, sniffing, coughing, and other tics—have all been described long ago by Janet and others as well recognized manifestations of hysteria. Recently there have appeared publications endeavouring to trace a psychical origin to the nervous and respiratory sequelae of encephalitis.

It must be conceded, however, that none of these arguments are conclusive. Many of the late manifestations of encephalitis—such, for example, as tremor—are similarly influenced by the emotional state of the patient. Thus, apprehension, fear, pleasure, are all factors which aggravate the tremor, though few would affirm that this was a symptom of psychical origin; most patients exhibiting the Parkinsonian syndrome are able to control the tremor for a short time by exercising a strong effort of will, just as many of the patients with tachypnoea can alter temporarily their respiratory rate, and make themselves breathe slower or deeper, shallower or faster. Far from being an indication of hysteria, therefore, this variability of symptoms depending upon different states of emotion and control is known to occur in many organic disorders. In all genuinely hysterical cases of disordered respiration other characteristic features of hysteria can readily be demonstrated. The course of the disease, moreover, is very different in the two conditions: in hysteria the respiratory anomaly is usually transient and rapidly yields to treatment by suggestion; in the post-encephalitic states, however, the outlook is grave—a few improve, some remain stationary for months, but the majority tend to become progressively worse, the physical and mental states simultaneously deteriorating. Many eventually drift into asylums, being affected with delusions and hallucinations, often highly systematized. It does not seem necessary, therefore, to seek for a psychical origin to the respiratory disorders of encephalitis any more than in any other organic psychosis; diffuse histo-pathological changes are readily demonstrable, and although the anatomical basis of such manifestations is still a matter of hypothesis, the physiology clearly entails a dissolution of the highest functions of the mind—judgement and inhibition.

Normal Physiology of the Respiratory Mechanism.

Normal automatic or unconscious breathing is effected through a so-called "respiratory centre," which is in reality made up of a number of anatomically separate areas situated in the pons and medulla. This centre is stimulated partly by afferent proprioceptive impulses from the alveoli of the lungs and the thoracic musculature, but mainly by the concentration of carbonic acid in the blood stream. The efferent impulses are conveyed along the lower neurones to the chest muscles and diaphragm.

Though the respiratory centre normally acts independently as a reflex phenomenon, it can be influenced by cortico-bulbar activity. Thus voluntary impulses, conveyed along the pyramidal tract, are capable of inhibiting or accelerating the respiratory centre so that an individual is able, temporarily at least, to hasten or retard his respiration rate, to take shallow or deep respirations, to assume an irregular rhythm, or to inhibit all respiration. Moreover, the respiratory centre is under the influence of other cortico-spinal impulses, which are correlated with the various respiratory irregularities occurring under emotional stress. Thus fright is associated with a temporary inhibition of respiration; pleasurable excitement with an acceleration. The gasping respirations which accompany crying and sobbing also illustrate the influence of the emotions upon the activities of the respiratory centre. There is a good deal of evidence—both experimental and anatomical—to suggest that these phenomena are conveyed along very definite psychomotor pathways. Spencer has demonstrated that these tracts originate in the prefrontal cortex and pass in close proximity to the optic thalamus to end in the lower pons. It is along these routes that the characteristic facial movements and respiratory changes are affected with emotional stimuli. It appears also that the pyramidal tract exercises partial inhibition over these psychomotor (or facio-respiratory) pathways; hence marked emotional instability and even spasmodic laughter and weeping after bilateral ablation of the pyramidal tracts are observed, as in pseudo-bulbar palsy. This normal inhibitory effect of the pyramids, though taking place partly in consciousness, is mainly a subconscious influence, and probably depends anatomically upon the presence of transcortical projection fibres between the precentral and prefrontal cortices.

The Disorders of Respiration.

The pyramidal tract cannot be implicated in the clinical manifestations of disordered respiration because of the absence of the characteristic changes in reflexes and the conservation of voluntary control. The respiratory centre itself does not appear to be the site of disease; there is little or no similarity in the diverse respiratory disorders to the dyspnoea of bulbar disease. It is improbable, too, that a medullary lesion would affect the centres subserving respiration and spare the other important nuclei closely aggregated in this region. Moreover, pathological evidence has failed to support this theory. Changes in the proprioceptive impulses or alterations in the chemistry of the circulating blood have never been demonstrated; the afferent stream of impulses to the medulla therefore seems to be intact. The efferent neuro-muscular mechanisms have been held responsible by some; it is improbable, however, that any such changes are present in all the types of disorder, although doubtless they are a factor in some. Thus rigidity, myoclonus, or tremor of the diaphragm can be demonstrated in patients showing a cogwheel type of respiration. It is obvious, however, that the pathogenesis of respiratory disorders as a whole is to be sought outside the efferent pathways.

Psychical and Sleep Disorders.

Stress has been laid upon the frequent occurrence of psychical and sleep disorders in association with respiratory upset; the association with the emotional instability of the patient lends weight to the view that the psychomotor pathways, with their transcortical projections, are the probable site of origin. An interruption in these latter fibres would abolish the unconscious control normally exercised by the pyramids over the emotional factors of respiration; we would expect, then, to encounter an unstable type of respiration, influenced by every variety of emotional play. The conscious and voluntary control, which we believe to be the function of the long cortico-bulbar fibres of the pyramids, persists; consequently the patient is able, by exerting a determined effort of will, to check or even arrest the abnormality of breathing. Many of these respiratory upsets are of a striking and alarming nature even to the onlookers. It is not surprising that the patient himself is profoundly impressed by the phenomena, and the emotion of fear thus engendered tends to maintain the abnormal respiration. The disease tends, therefore, to perpetuate itself, owing to the complete emotional instability and the lack of equanimity and self-confidence.

Reference has been made to the occurrence of respiratory disorder during sleep; many authors have pointed out that towards nightfall the patients become restless and excited, and frequently noisy and unruly—in striking contrast to their diurnal somnolence and placidity. Simultaneously there is an aggravation in the respiratory disorders. These facts can be reconciled with a tiring-out of the processes of inhibition which have been active throughout the day-time, so permitting conduct and respiratory anomalies to manifest themselves unchecked.

The researches of Pavlov have done much to throw light upon the physiology of the highest cortical processes; they have revealed that many of the seemingly complex activities of the cortex are in reality the resultant of definite conditioned reflexes and their antagonistic inhibitory influences. The study of behaviour in animals after ablation of small areas of cortex demonstrates that there is a temporary upheaval of the normal conditioned reflexes, and that the inhibitory processes are affected to a much greater extent than the excitatory. More extensive damage to the brain produces a permanent weakness of the inhibitory processes. A similar state of affairs appears to exist in many cases of post-encephalitic respiratory disorder, where there is an obvious impairment of inhibition on the part of the patient, although the conditioned reflexes can still be checked temporarily by unexpected extraneous stimuli (external inhibition).

It appears, therefore, more in accord with the modern conceptions of neurology to regard these "psychical" changes following encephalitis (conduct and sleep disorders, respiratory abnormalities) as essentially physical in origin. I submit that the respiratory disorders are essentially organic in their pathogeny, and suggest that they arise from disorder of the psychomotor pathways controlling the respiratory centres, together with a defective inhibition by cortical control.

EXPERIMENTS ON THE RADIATION OF TUMOURS.

WITH SPECIAL REFERENCE TO THEIR BLOOD SUPPLY.

BY

J. C. MOTTRAM, M.B.LOND., D.P.H.CANTAB.

(From the Research Laboratory, Radium Institute, London.)

THE clinical treatment of tumours by radiation brings out two outstanding facts: first, that there are wide differences in the sensibility of tumours of different kinds; and secondly, that tumours of the same kind in different patients also vary in sensibility, though the variations are less wide than when tumours of different kinds are compared. At present there is no way of estimating these differences before treatment. The first kind of variation has been considered to reside in the tumour cells, but when different kinds of tumour cells are irradiated *in vitro* the lethal dose is found to vary very little. The second kind of variation must reside in the patient, and has been assumed to be due to a resistance towards tumour growth, which varies from patient to patient. Thus, it is evident that we have no certain explanations for the two most important clinical facts, and in order to elucidate them the following experiments have been carried out.

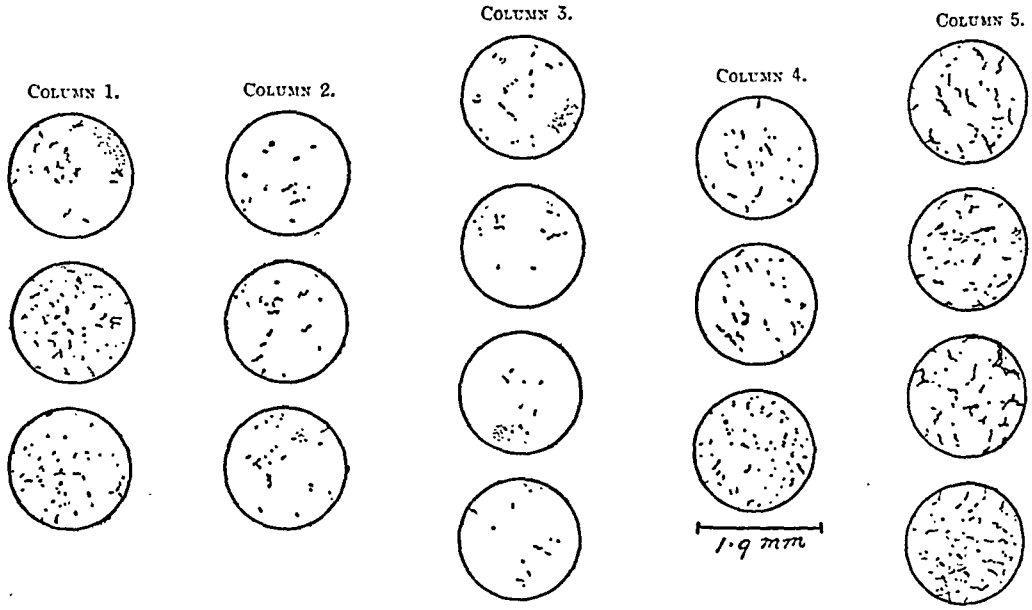
When a tumour is radiated *in vivo*, then removed at once,

and placed in another animal, the factor of resistance will be avoided apart from its operation during the few minutes in which the radiation is being applied. If, on the other hand, the tumour after radiation be left in the animal for varying lengths of time before removal and inoculation into another animal, then the factor of the host will operate more or less according to the length of time that it is permitted to remain in the host after radiation. By comparing these two sets of experiments the influence of the host will be demonstrated.

Experimental Details.

In order to avoid as far as possible normal variations in tumour growth, a tumour (mouse sarcoma No. 180) was chosen which grows in nearly 100 per cent. This was kindly supplied to me by Dr. Woglom from the Cancer Research Institute, Columbia University. Dr. Woglom stated that "in the ten years or so that we have been cultivating it I cannot remember one single regression." During this investigation 84 control inoculations have been made, with 75 takes; there were no regressions. Of the 9 negatives, 5 occurred in a single batch in which a much degenerated tumour was used. The experimental procedure was as follows:

Mice were inoculated in the flank with small pieces of tumour, approximately 1 mm. cube. When these had grown to approximately 4 by 4 mm. superficial area they were radiated with a radium application of 20 mg. of radium element, area 15 by 15 mm., screen 0.35 mm. silver. The exposures were for ten, fifteen, and twenty minutes. Either at once, or after varying lengths of time (from three to seven days), the mice were killed, and the tumour exposed by removing the skin. A thin slice, 1 mm. thick, of the tumour was taken from the surface, divided generally into six pieces, and inoculated into mice.



Results of Radiation.

When Tumour Removed.	10 min. Radiation.	15 min. Radiation.	20 min. Radiation.
At once	6/6	11/18	4/12
After 3 days	3/6	2/6	5/10
After 4 days	5/6	1/6	0/6
After 5 days	2/4	0/6	0/6
After 6 days	4/6	0/6	0/4
After 7 days	6/6	0/3	2/10

The denominators of the fractions give the number of inoculations, the numerators the number which grew into tumours.

The results show that the chance of the inoculation growing is much greater when the radiated material is removed at once than when removal is delayed for a period of four to six days. Just as the number of takes is reduced in this manner so also, as would be expected, is there a difference in the time of appearance of the tumours and their liability to regress. Tumours which grow from the inoculation of pieces taken four to six days after radiation take much longer to appear (about twenty-one days) than tumours growing from pieces taken immediately after radiation (about seven days), and whereas cases of regression and disappearance of tumours occurred amongst the former, none were observed in the latter. These findings go to show that the figures given in the table are not the results of chance, but of the arranged experimental differences.

At first sight these results suggest that there is in the mouse an inhibitory factor towards the growth of sarcoma 180, which accounts for the differences obtained, according as to whether the radiated tumour cells are removed at once or after varying lengths of time. On the other hand, the results can equally well be explained by assuming that the radiation produces effects in the tumour which do not manifest themselves for several days. One such effect has been observed. It is well known that radiation has produced effects on blood vessels. An early effect is swelling of the endothelial cells, which obstructs the blood flow through the arterioles and capillaries. This obstruction to blood flow is to be seen in the living mouse in the neighbourhood of the radiated tumour. On about the fourth day after the tumour has been radiated the normal pink colour of the skin and underlying tumour disappears, and is replaced by a bloodless yellow colour. I have had occasion recently to radiate chickens. Their skin is very thin and transparent, so that the pink colour of the underlying tissues can be easily seen. Twenty-four hours after a large dose, and two days after a moderate dose of radiation, using square radium applicators, a square white area is seen where the application was made, which is very marked after three to four days, and persists for a few weeks. These observations suggest that the normal blood supply to the radiated tumour may be interfered with at this time. In order to test this the following experiments were made.

Experimental Details.

Tumours were exposed for twenty minutes to the applicator *in vivo*. After varying lengths of time the tumours were removed so as to preserve as far as possible the amount of blood which they contained during life. The animals were etherized. The skin for about 1 *cm.* around the tumour was burnt through with a cautery, then ligatures were passed under the tumour, and the deep connexions tied off. The whole was then removed and fixed in formol Müller. Sections 5μ thick were made, stained with aniline fuchsine, decolorized with 0.5 per cent. ammonia solution, and counterstained with iron haematoxylin. In this way the red corpuscles show up intensely red against a grey background. Control

specimens which had not been radiated were similarly prepared. Using a square graticule in the eyepiece of the microscope, drawings were made, on squared paper, of the red cells seen. In this way a picture of the amount of blood in the capillaries was obtained. No differences between experiment and control were found in the twelve-hour and twenty-four-hour specimens. The results obtained with intervals of two, three, and four days are illustrated in the accompanying figure, which shows the drawings obtained as described. In choosing a piece of tumour to draw, an area of the section was always selected where blood vessels were most numerous and the tumour neither degenerated nor necrotic.

It will be seen that after two days (column 1), and especially after three and four days (columns 2 and 3), the capillaries in the radiated specimens contain very little blood as compared with the control specimens (columns 4 and 5). The areas of fine scattered dots represent haemorrhages, and it is seen that these are more numerous in the experimental animals. The differences which have been observed may therefore be well accounted for by the fact that tumour cells allowed to remain in the body after radiation suffer from an interference with their blood supply, as well as from the direct effects on them of the radiation.

Theoretical Considerations.

Starting from this fact, there arises the question whether the difference in radio-sensibility between normal tissues and tumours is related to effects on blood vessels. It is known that tumours, and especially malignant tumours, have an inefficient vascular supply. Any interference with this will thus operate against them more than against normal tissues. Further, in many malignant tumours the supply of blood is so poor that necrosis is of common occurrence, apart from radiation. Such tumours are especially sensitive to radiation, after which widespread necrosis may occur. Rapidly growing tumours, which presumably make a large call on the blood supply, and tend to outgrow it, are likewise said to be especially sensitive to radiation. Non-malignant tumours seem to fall into line as their vascular supply is less differentiated than normal tissues, but more than malignant tumours, whilst the sensibility is likewise intermediate. How far this hypothesis will account for the facts of radiation remains to be seen; it is now put forward as a working hypothesis which may prove useful in therapeutics.

Conclusions.

1. Tumours left for four to five days in the animal after radiation, and then removed and grafted into other animals, succumb more easily than when removed immediately after exposure.

2. This effect is associated with an interference with the blood supply, which occurs four to five days after the exposure.

3. These results suggest the hypothesis that the varying sensibility to radiation of tumours, and the difference in sensibility between normal tissues and tumours, are associated with the variations in blood supply, on which the radiation has a special action apart from its direct action on cells.

ASTHMA WITH MAXILLARY SINUSITIS AND A HEALTHY SUPERNUMERARY PARANASAL SINUS.

BY

W. S. THACKER NEVILLE, M.D., F.R.C.S.E.,

DARLINGTON.

THE patient whose case is recorded below is a medical student, aged 20, whose studies were interfered with by recurrent attacks of asthma. He came to see me on August 7th, 1926, and gave the following history.

He said that he had had bronchitis in October of the previous year, and that after three days in bed asthma developed, the attacks continuing during the succeeding three weeks. He then studied in London for the primary Fellowship examination, and while there was free from attacks, but on returning home, where he remained until the end of January, 1926, he suffered from slight attacks of asthma occasionally, with shortness of breath on exertion. On resuming work at a university in the North of England he had severe attacks for three nights, so he returned home. He had shortness of breath each morning, and asthmatic attacks at intervals of five or six weeks, each attack lasting for a week or two. For three weeks before coming to me he had never once been free from asthma. He had used adrenaline frequently, and had had four injections of peptone during the week in which I saw him.

I found his nose normal, except for a few threads of mucus extending from the septum to the lateral walls; some mucus was present on the floor of the nasal orifice. The tonsils and adenoids had been removed in childhood, but a portion of the left tonsil was still present. The larynx and vocal cords were red, and the trachea, which was easily exposed, was injected. On transillumination both maxillary sinuses were dark. By puncture and washing a mass of mucoid material was expelled from the right sinus; the left sinus showed only a few strings of mucus. Three days later the patient returned, and said that he felt better than for many weeks. Puncture was again performed, and on this occasion a mass of mucoid material was expelled from both sinuses. On the next day puncture of the right sinus revealed the same condition, but the left sinus washing was clear.

On August 14th a Caldwell-Luc operation was performed on both sides, the anaesthetic employed being morphine and scopolamine, with local injections of 1/2 per cent. solution of novocain, and the application of cocaine paste in the nose. On the right side a small normal sinus was exposed, and a counter-opening was made posteriorly below the inferior turbinate; the wound was then sutured. The left sinus was found to be similar to the right, but perforating a thin partition brought to light a sinus lined with polypoid mucous membrane, on the floor of which a strand of pus was lying. The sinus was scraped with a curette round which was wound gauze soaked in 10 per cent. zinc chloride solution, and the partition, which had completely divided the antero-median from the posterior lateral sinus, was removed. The sutures on the right side were then taken out and a similar partition was discovered, which, on removal, opened up a sinus presenting the same pathological appearance as the left.

By September 16th the patient had been free from asthma for about a month; on recurrence then, I washed out the sinuses and retained secretion was found. I removed the anterior ends of the inferior turbinates, and enlarged the intranasal opening to enable the patient to use lavage himself. On October 21st the patient, who was regularly washing out the sinus, reported freedom from the asthma and an increase in weight; he was only troubled now by a slight cough at night, due to the bronchitis which so often follows sinusitis. Two days later he stated that, after washing the sinus twice a day for a month he had abstained for thirty-six hours from lavage, when a violent attack of asthma supervened, necessitating the use of morphine. This was an indication that the patient was sensitive to his own protein.

The anatomical condition in this patient explains why on two occasions the washings from the left side were negative, and how, although proof puncture had shown the presence of disease on the right side, yet a healthy sinus was found, but, when the partition was removed, a polypoid mucous membrane was exposed to view. I have previously reported the occurrence of similar anatomical anomalies of a less degree in two patients in China. The origin of supernumerary paranasal sinuses is discussed by Schaeffer. It would appear that the medial healthy sinuses originate from the naso-palatine canal, while the diseased sinuses are the true maxillary sinuses. In my case the condition was deceptive as the partition was complete. From the clinical aspect the history of asthma for only ten months pointed to a focus of infection somewhere, yet if transillumination had been omitted from the routine examination the focus would not have been discovered, for the patient had no idea that he had any lesion in his nose; there was no localized oedema or hypertrophy, and no discharge was seen near the middle turbinate. The condition is interesting, as the patient seems to have been sensitized to his own protein, and was always relieved by an adrenaline injection.

A CASE OF SELF-MUTILATION.

BY

DOUGLAS J. A. KERR, M.B., CH.B.ED.,

ASSISTANT, FORENSIC MEDICINE DEPARTMENT, EDINBURGH UNIVERSITY.

THE following report is of considerable medico-legal interest, and though cases of self-mutilation occasionally occur, chiefly in asylums, the accompanying illustrations are probably unique in the annals of forensic medicine.

The deceased was a healthy man until two years before his death, when he contracted rheumatism, which prevented him from working. Since then he had been unemployed, and his landlady noticed that he was becoming strange in his manner.

About 10.30 one morning he left the house, saying he would return at midday for his dinner; he appeared to be depressed, and was under the delusion that he had killed his sister. He was not seen for two days, when he was found lying in a field on the outskirts of Edinburgh; his clothes, with the exception of his trousers, socks, and boots, had been removed, and he was seen to have numerous wounds on the head, throat, and body. He was taken in an ambulance to hospital, where he arrived in a very collapsed condition, almost pulseless. He was conscious, and understood directions, but was too weak to talk. The wound in his throat was septic and crawling with maggots, but not bleeding. He died eight hours later.

Ventral aspect.

Left hand. Head and neck. Right hand.

Post-mortem Examination.

Lividity was well marked. The internal organs and brain were normal in appearance. All the organs were plentifully supplied with blood, and death had not taken place from haemorrhage. The body showed over four hundred and forty different cuts, chiefly superficial, though in a number of instances, such as on the back of the left arm, on the fingers and throat, the underlying muscles were divided.

The main wound was in the throat; it started just below the lobe of the left ear, and passing immediately above the thyroid cartilage it ended at a point on the lower jaw midway between the angle and the symphysis menti. The incision had severed the sterno-hyoid and omo-hyoid muscles on each side, but the main vessels and air passages were uninjured The wound was septic and crawling with maggots. Immediately above the main wound, at its commencement on the left side and parallel to it, was a smaller wound, 2 in. in length, which penetrated the muscular tissue. A similar wound was situated just below the main wound. In addition to these wounds the following cuts were found:

Forehead 5—extending across the greater part of the forehead.
Chin and neck 27—two extending round the right side of the neck as far as the mid-line behind.
Chest 72.
Left axilla and side of chest 27.
Abdomen 168.
Left arm: Palmar surface—palm 24, fingers 15, wrist 4, forearm 6. Dorsal surface—hand 2, fingers 13, wrist 2, forearm 6.
Right arm: Palmar surface—palm 26, wrist 12. Dorsal surface—hand 2, wrist 10, fingers 21.
Scrotum: Six faint scratches on the most dependent part.

The wounds had been inflicted with a somewhat blunt penknife having a blade 1¾ in. long, which was found in the field near the deceased.

Comment.

The case presents many points of medico-legal interest. The number and character of the wounds are typical of *self-infliction and mental derangement*. Similar cases have been recorded, one of the most striking being that noted by Maschka (*Prag. med. Woch.*, 1888), and referred to in Dixon Mann's *Forensic Medicine*. In this case a man, who was an inmate of an asylum, inflicted 285 punctured wounds on himself, 200 being on the left side of the chest, 50 on the left forearm, and 28 on the right forearm.

In the case here recorded, in addition to the injuries on the trunk and arms, the forehead, chin, and cheeks had been extensively slashed. Of special interest are the cuts on the palmar aspect of both hands. This is a most unusual place for self-inflicted injuries. Incised wounds on the palms and fingers are regarded as characteristic of injuries resulting from an attempt to ward off an assailant armed with a knife or razor, by seizing the blade with the hands. Had this case shown only such wounds on the hands and the wounds on the throat, a strong suspicion of homicide would have arisen

The cause of death is also interesting. No vital structure was injured, and the loss of blood had been slight, as was shown by the well marked *post-mortem* lividity and the condition of the internal organs. Judging from the condition of the wound in the throat and the time of his disappearance, the man had apparently been lying out in the field, after the wounds had been inflicted, for two days and nights, clad only in a pair of trousers. This, together with the general healthy state of the organs and absence of disease, justified the inference that death had resulted from exposure and shock.

I am indebted to Professor Littlejohn and Professor Lorrain Smith for permission to publish this case.

MASTOIDITIS LIMITED TO THE DEEP SUBANTRAL CELLS.

BY

J. B. HORGAN, M.B., CH.B., D.L.O.,

HONORARY LARYNGOLOGIST, NORTH INFIRMARY, CORK.

THE case here reported illustrates the potential difficulties and vagaries of mastoid surgery and the importance of Mouret's[1] teaching as to the necessity of exploring not only the superficial but the deep subantral cells for the possible *extension of disease in every case of acute mastoiditis.*

A professional man, aged 42, was referred to me on June 29th, 1926, suffering from severe pain in the left ear and left temporal region. It had been present for five days; a discharge from the left ear which had been in evidence for three days had ceased. I encountered some difficulty in viewing the left tympanic membrane owing to exostoses. It was hyperaemic, but the anatomical landmarks were still apparent and the hearing was but slightly impaired. The pulse and temperature were normal, but as there was marked tenderness over the mastoid and temporal regions I at once performed a linear paracentesis of the posterior segment of the membrane and confined the patient to bed. There was no discharge from the ear then or later.

During the succeeding days the patient complained of intermittent radiating pains in the left mastoid and temporal regions, especially at night; these were sufficiently severe to necessitate the administration of sedatives to induce sleep, but they tended to become less, as also did the mastoid and temporal tenderness. A four-hourly temperature and pulse record failed to reveal the smallest abnormality.

On July 9th I noticed very slight paresis of the left side of the face, only evident during emotional activity. As this became much more marked on the following day, I decided to explore the mastoid bone. This proved to be a matter of extreme difficulty owing to its density, the superficial and anterior position of the *sigmoid sinus (which lay only a few millimetres below the cortex* and immediately behind the posterior meatal wall), and to the downward and lateral inclination of the middle cerebral fossa. The mastoid antrum, which lay at more than one inch from the surface, could only be reached by the use of a 2 mm. chisel in the very small triangle of dense bone which was circumscribed by the middle fossa, the sigmoid sinus, and the posterior wall of the bony meatus. It was small and contained a somewhat slightly turbid fluid. By applying pressure to the antral floor with a small sharp spoon I succeeded in opening into a small cellular area which lay in close proximity to the descending limb of the facial canal and which was found to contain purulent fluid. Cultural examination of both the antral and cellular contents yielded a pure culture of the *Streptococcus mucosus*. A careful examination failed to reveal any extension of the disease to the *temporo-zygomatic cells*. A small rubber drainage tube was inserted and retained for four or five days. The facial paralysis disappeared very quickly and the bone cavity was rapidly obliterated.

The deep subantral cells, which may often be prolonged into the interior of the pyramidal portion of the bone, in the space subtended by the labyrinth, the jugular bulb, the cerebellar fossa, and the facial canal, communicate with the inner half of the floor of the mastoid antrum. There may or may not be a connexion between them and the *more commonly affected superficial subantral cells, which,* as in this case, may be entirely absent. When both sets of cells are simultaneously affected the more apparent symptoms resulting from lesions of the external cells may mask those pertaining to a lesion of the deep, which latter, more especially in the absence of a direct communication with the superficial cells, may continue to advance. These deep lesions, which evolve slowly, may elude the attention of the less observant clinician and end by causing extensive havoc in the depths of the bone, implicating, on the one hand, the aqueduct of Fallopius or the cerebellar fossa (meninges or terminal part of the lateral sinus), or, on the other, the deeper planes of the neck.

HENOCH'S PURPURA IN AN ADULT.

THE following case appears of sufficient interest to be placed on record, since all the symptoms seemed to point to an "acute abdomen" until the purpura appeared.

A man, aged 44, came to my surgery in July, 1926, complaining of pain in the stomach, which was worse after meals; there was no vomiting and no pain on palpation. I gave him a rhubarb and soda mixture; one week later the pain had gone and he stated he was now quite well again.

On November 26th, in the afternoon, while the patient was walking he was suddenly seized with an acute abdominal pain "doubling him up"; this became gradually worse and he passed what he stated to be a good motion. The pain remained severe, and at 9 p.m. he looked collapsed, but the pulse was 74 and the temperature 97.4°. On examination his stomach was hard, and moving little if at all on respiration. By palpation it was difficult to make anything out as the muscles were rigid, but pain was found in the right iliac fossa. On percussion there was a resonant note all over; the liver dullness was lessened and the tongue was furred.

The patient had a bad night, and on the next morning the pulse was 76 and the temperature 97.2°. The pain, severe all over the abdomen, which was still rigid; it was worst in the left iliac fossa. The urine was smoky; it contained blood and slight albumin. On the next morning the *pain continued* severe, the pulse 82, and the temperature 100.1°. The abdomen was still hard and painful to palpation all over; he had been given small doses of calomel and salts but had vomited them, the vomit being bile-stained. After two enemas with no good result, he passed in the evening a motion which contained obvious blood, some bright red and some dark. In the early morning of November 29th he had severe pain over the left base, resembling pleurisy, but at 11 a.m. he was much better, the pulse and temperature were normal and there was less rigidity of the abdomen. At 11 p.m. he was reported to be unconscious after a bout of *wild excitement* in which he tried to get out of bed. I found the patient asleep, bathed in perspiration, and covered with a typical purpural rash. Since then he never looked back; the pain entirely disappeared, and the urine and faeces contained no blood.

I think this is clearly a case of Henoch's purpura in an adult, but until the rash appeared I at first suspected, from the previous history, a perforation; when the temperature rose on November 26th acute appendicitis seemed possible. I notice that in the 1925 edition of Taylor's *Medicine* it is stated that this purpura may be confused with intestinal obstruction, but this was put out of court in my case by the motion on the 26th; had not the pulse remained quiet I would certainly have sent him into a nursing home for surgical treatment. The pain and rigidity were obviously due to haemorrhage into the bowel wall.

High Hesket, Cumberland.

DIVERTICULITIS OF THE CAECUM.

THE following case appears to be worthy of record owing to its unusual features.

A woman, aged 54, had vomited and then was attacked with severe pain in the right lower abdomen at about 9.30 a.m. on October 31st, 1926. She had felt slight abdominal discomfort on the previous day, but put it down to "indigestion."

On examination there was rigidity and tenderness in the right iliac fossa and a small lump was felt in the appendix region. The pulse was 120 and temperature 99°. With these signs and symptoms the case was considered to be a small appendicular abscess *with dense adhesions.*

Operation.—The abdomen was opened in the afternoon by Mr. L. E. Barrington Ward, F.R.C.S., by a right paramedial incision, and the rectus muscle was retracted inwards The appendix was apparently normal, but there was a large quantity of free fluid in the abdomen. On palpating the caecum, which was covered with plastic lymph, showing that definite peritonitis was present, a mass was felt which appeared to be incorporated in its wall. An alternative diagnosis was made of diverticulitis or new growth. The caecum and part of the ileum was excised and the terminal portion of the small intestine was anastomosed to the ascending colon. The patient stood the operation well and made a good recovery.

The pathological report was that the peritoneum covering the caecum was acutely inflamed and great engorgement was present. Opening into the caecum about one inch from the appendicular orifice was a diverticulum about half an inch long. The mucosa of the diverticulum was inflamed and contained a faecalith. Cross-section of the caecum showed the mucous membrane of the diverticulum partly ulcerated and extending through the muscular coat of the caecum as far as the subperitoneal.

This case is of interest on account of the uncommon situation for diverticulitis to attack the large bowel, and illustrates how difficult an apparent appendix operation may turn out to be in general practice.

London, N.10. HAROLD PEREIRA, M.R.C.S., L.R.C.P.

OBESITY OF PITUITARY TYPE PROBABLY A SEQUEL OF ENCEPHALITIS LETHARGICA.

THE following case was shown at a clinical meeting for the diseases of children held by the Ulster Medical Society on January 13th.

The patient, a girl aged 10 years, was the youngest of three children; there was nothing abnormal in the physique of the parents or other children.

The history was that she was a normal healthy intelligent child, apart from periodical attacks of vomiting, until she reached the age of 7 years, when she had an attack of "appendicitis," the pain being treated "for a week with poultices." Shortly after this she developed tremors, "shakiness," squint, and began to increase in weight. She became mentally changed, developed phobias, was stupid and dull, and fell asleep easily. Her grandmother says "all she knows now she knew when she was 7 years old."

At 10 years she is 49 inches in height, the symphysis pubis being midway, and she weighs 82 lb. The fat deposit is evenly distributed over the body, being of the pre-puberty dyspituitarism type (Fearnside). She is stupid and dull. The Wassermann reaction of the blood is negative. The cerebro-spinal fluid was under slight pressure; it contained no cells; there was no increase in globulin, chlorides 0.74 per cent., sugar 0.07 per cent. There is a slight degree of optic neuritis (right) and paresis of the sixth right cranial nerve. An *x*-ray plate of the skull shows a questionable slight irregularity of the posterior clinoid processes.

It is suggested that this child's present condition is a rather uncommon sequel of an attack of encephalitis lethargica three years ago.

F. M. B. ALLEN, M.D., M.R.C.P.Lond.,
Assistant Physician to the Belfast Hospital for Sick Children.

AN OCCUPATIONAL BURSA OF THE HAND.

MANY types of occupational bursae have been described from time to time. This described here is unfamiliar to me, at any rate. It occurred in a railway carriage cleaner, who had followed his occupation for seven years, the last three of which had been on piece-work; it was during these last three years that he had noticed his affliction. On the dorso-medial aspect of the right thumb, opposite the metacarpo-phalangeal joint, appeared a painless swelling, semi-fluctuant, and measuring about 1¼ in. vertically by 3/4 in. laterally. He was right-handed, and his method of reaching the high carriage windows was to use his left hand to steady his brush whilst his right hand supplied the motive power. Consequently, the region of most constant pressure was the angle between the right thumb and forefinger which gripped the brush. The bursa had formed over the most prominent bony point in this region—namely, the base of the proximal phalanx of the thumb. It began as a slight thickening of the skin, and not by "blister" formation, as is met with in the hayfields.

The patient states that five of his mates have identical swellings, though varying in size; amongst the cleaners they are called "pig's feet." It is always interesting to observe the protection provided by nature for a part required to perform some special function; this, I think, is some justification for mentioning the case.

Bradford. B. W. RYCROFT.

British Medical Association.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

GLOUCESTERSHIRE BRANCH.

A MEETING of the Gloucestershire Branch was held at the General Hospital, Cheltenham, on January 13th. Dr. J. RUPERT COLLINS presided, and Dr. J. S. KELLETT SMITH gave an address on the redundant colon, with radiographic illustrations.

Dr. Kellett Smith said that many people were born with a large intestine too long for comfortable disposition in the abdominal cavity, and necessitating its arrangement in exaggerated or adventitious loops, which might properly be termed redundant. He showed a table illustrating the variation in length of the large intestine, the difference between minima and maxima being roughly 100 per cent. It was important to note that the full variation was in evidence at birth, and was not the result of diet or habit. Bryant was quoted as concluding, from 160 *post-mortem* examinations, that in 15 per cent. of people the intestine was so far above the average length as to necessitate redundant loops which might cause trouble. It was emphasized that a loop was in no sense a stricture; in many cases it caused no trouble, and when trouble did ensue it was the logical sequence of the tendency in a loop to obstruct if it became overfilled, twisted, or kinked. The symptoms were constipation with absorption results, occasional diarrhoea, very occasionally vomiting, and gas, with abdominal distress, due to partial obstruction or interference with the colon blood supply. A characteristic symptom was the sensation of gas passing an obstruction, with consequent relief; belching of wind was common. Abdominal pain, from mild grumblings to violent colic, might be present, and complete obstruction from acute volvulus might occur. Intermittent tumours had been described. The symptoms were in themselves of a general character, and not diagnostic alone. The diagnosis was made by *x*-ray examination after a barium enema. Dr. Kellett Smith had had 14 cases in the past twelve months, and he briefly outlined the details. The condition of the colon in each case was shown in a series of very excellent films, which brought out clearly the various types of redundant colon, including the adventitious loops found chiefly on the left side. The symptoms in the cases described included those detailed above, with also in one case the passage of pure blood in considerable quantity from the bowel.

The PRESIDENT, while admitting that there were very few departments in medicine in which more help was obtained from the radiologist than in opaque meal cases, advised caution in assuming that the demonstration of a redundant colon immediately interpreted all the symptoms. In his opinion the treatment of the patient should overshadow local treatment in these cases. Dr. MEYRICK JONES mentioned some of the pitfalls in barium work, and congratulated Dr. Kellett Smith on the uniform technical excellence of his skiagrams. Dr. SOUTAR emphasized the fact that auto-intoxication was a very real clinical condition, and one which in neurasthenias and psychasthenia had constantly to be investigated. In his view it was advisable to explain to a patient so far as possible the origin of his symptoms, as his co-operation was thus more readily secured, and this was an invaluable factor in treatment. Dr. FORSTER mentioned a woman patient who said her bowels moved regularly, but questioning elicited the fact that the regularity was "every third Sunday morning." Dr. CURTIS WEBB put in a strong plea for the restriction of purgatives in such cases, and the substitution of the enema. He had found, when the abdominal wall was lax, as it usually was, that it was useful to begin building up the feeble abdominal muscles with the faradic current before attempting much in the way of exercises. In his experience pain in redundant colon, due to congestion at a loop, was frequently relieved by diathermy. Other members discussed the paper, and in reply to various questions Dr. KELLETT SMITH gave an outline of the treatment which had been found useful in his cases by the medical men who had charge of them. The Americans believed in "oil above and oil below." Normacol had proved valuable. He agreed with washing out rather than the use of purgatives, and recommended potassium permanganate injections.

Dr. J. B. DAVEY showed pathological specimens. (1) Cauliflower type carcinoma of pyloric end of stomach, with secondaries in head of pancreas and liver; it weighed 14 lb. 2 oz. (2) Large fibro-adenoma of breast in a girl aged 14, following on a blow six weeks before admission. Clinically sarcoma was suspected. (3) Clot containing microscopic fragments of carcinoma of colon, passed per rectum by a man with three weeks' history of passing blood and mucus. He had been regarded as a case of mucous colitis. Subsequently a large fungating growth of the sigmoid was detected by sigmoidoscope.

The PRESIDENT showed a boy, aged 6, weight 1 st. 12 lb., suffering from infantilism and chronic diarrhoea. The stools contained 60 per cent. fat. The diagnosis was discussed. Dr. ALLMAN POWELL demonstrated a case of

senile pruritus in which injections of adrenaline had acted like a charm. A man was shown, who was under the care of Mr. Pike, with proptosis. He had hard glands in the neck, and one of them, removed the previous evening, was shown by Dr. Davey to be invaded by carcinoma.

Reports of Societies.

ACUTE POLIOMYELITIS.

DISCUSSION BY THE MEDICAL OFFICERS OF SCHOOLS ASSOCIATION.

AT a meeting of the Medical Officers of Schools Association on February 4th Dr. JAMES COLLIER read the opening paper in a discussion on acute poliomyelitis.

The pathological aspect of this disease, said Dr. Collier, was admirably treated by Dr. F. E. Batten in his Lumleian Lectures in 1916, and since that date little had been added except by way of confirmation, though a few cases of the then undescribed encephalitis lethargica, which had crept into Dr. Batten's description as poliomyelitis, had had to be separated. The epidemiological and public health aspect of the malady bristled with difficulty, potential danger, and paradox. When the speaker first entered on medical study, forty years ago, there was no suggestion that poliomyelitis was an infectious disease; twenty-two years ago the view was put forward that it was infectious by contact only, but now some, including himself, were beginning to think that poliomyelitis was not infectious in the sense of case-to-case infection, and that the future was likely to prove that only carriers could spread the disease. Poliomyelitis, however, was a condition with many unexpected phases, and no one could prophesy what it might do. Would it disappear silently, and then reappear in the form of a violent epidemic? He thought it unlikely that it would play any terrible havoc in this country unless it first of all entirely disappeared. For there was always poliomyelitis amongst us—in London there were cases in every month of every year—and therefore the community was, so to speak, a "salted" one. But who, from his knowledge of poliomyelitis, could have predicted that in one comparatively small area in the world tens of thousands of cases would occur in the space of a few years, culminating in 5,000 deaths in New York and adjacent States in the autumn of 1916; or that in one small isolated village in the West of England, with a total population of 119 souls, forty-five persons should be seized with poliomyelitis in the course of a few days, every house having its two or three for four victims, as happened in the Devon and Cornwall outbreak of 1910? Every form of the disease was seen in that village within a week, and yet in the same year, in Edinburgh, there were, he thought, sixty-two cases, all of the usual spinal type, and no two cases occurred in one family or in one street. He remembered that the two reporters who brought before the Epidemiological Section of the Royal Society of Medicine an account of the outbreak respectively in the west country and in Edinburgh had a very different reception from the audience present on that occasion. The audience patted the Devon and Cornwall man on the back, commending him especially for his powers of observation, and was quite rude to the Edinburgh reporter, whose contribution was thought to be from an epidemiological point of view not nearly as valuable, and it was suggested that he had missed cases or types of cases; yet both these reports were of the highest value as examples, the one of poliomyelitis running riot in a susceptible community, the other of poliomyelitis epidemic in a highly "salted" community, with multitudinous carriers.

Dr. Collier then passed in review some of the clinical features of poliomyelitis. Lumbar puncture was the most useful measure in making a correct diagnosis from the earliest appearance of symptoms until some days after the pyrexia had disappeared. It was also a means of permanently removing some of the most distressing symptoms. The grouping of the forms of the disease on an anatomical basis, as suggested by Wickman, had been criticized as neither clinical nor scientific, but it was a useful aid to memory and thought. No one had yet made a better classification, and Dr. Collier proceeded to describe the characteristics of each of the forms there set out: the abortive, the neuritic, the spinal, the meningitic, the brain-stem, the cerebral, and the cerebellar. The carrier, he said, was not a hypothetical individual. He had been caught after infecting others, and his virus obtained. Sometimes, though rarely, the carrier himself succumbed to the disease. It was a chain of carriers who perpetuated the disease and passed it on from season to season. Some of the forms just mentioned—the spinal, for instance—were so well known as to make description superfluous, but there were several peculiar varieties of the spinal form which deserved special mention, and the lecturer gave particulars of some illustrative cases. The neuritic type of poliomyelitis was nothing more than the same variety in which there was great pain and tenderness in the paralysed region, sometimes to such an extent as to increase the apparent paralysis to completeness. This was the most interesting variety of the disease from the pathological point of view. It was sometimes troublesome in diagnosis. He had many times been called to see cases of acute rheumatism as cases of poliomyelitis, but it was well to remember that while pain generally increased the reflexes, both superficial and deep, poliomyelitis generally abolished them. The brain-stem form he left undescribed, because he had not seen one himself, and he was rather unconvinced by any description.

There were a number of curious relapsing cases in which the patient seemed to become apyrexial and convalescent, and after a few days all the original symptoms returned. These were examples of a second blaze of infection which had remained alive in the tissues. Such relapses might be anticipated by watching the temperature chart. If instead of the customary peak there was a flat-topped temperature curve for the first few days, and little jumps of temperature in the apyrexial interval, a relapse might be expected. Whatever the textbooks might say about dreadful results in relapses, he had never seen any harm occur. There was no increase of paralysis from the relapse. Indeed, in a case which he saw of an eighth-day relapse, with high fever and great restlessness and headache, it was obvious that the paralysed legs were improving continually. Very rarely one saw a case of poliomyelitis in which the types were mixed, though he had seen a certain number. There were also cases which showed no pyrexia or headache, but only paralysis; such cases, he thought, were always of the purely spinal type. He had not seen more than half a dozen apyrexial cases. A great many rashes had been described in poliomyelitis, but two were worthy of mention. One was herpes zoster, and the other a striking rash of most peculiar appearance and distribution, consisting of large bluish papules distributed over the paralysed region only. He had seen this rash half a dozen times. Possibly it was of the same pathogeny as herpes zoster, but herpes zoster had always a very curious distribution in patches, which was not the case with this eruption.

Dr. Collier closed with a word of consolation to school medical officers. This disease, he said, did not like schools, institutions, or large communities. In one of the bad epidemics in America forty-five schools in the infected locality, containing 3,600 children of susceptible age, were kept under observation, and only one case occurred. At the Hospital for Sick Children no case had been recorded of the spread of the infection to another child. How was this to be explained on the theory of case-to-case infection? Take what happened at Broadstairs in 1926. All the cases occurred in a few days, and then there were no more cases. He commended to the general notice two fascinating pieces of work—one by Topley and Greenwood, communicated in 1926 to the Epidemiological Section of the Royal Society of Medicine, on the subject of infection in a community of mice, and the other by Surgeon Commander Dudley, in a report issued by the Medical Research Council, on the spread of droplet infection in semi-isolated communities.[1]

The discussion chiefly took the form of questions addressed to the lecturer, the first of which was whether a carrier could be detected without resort to lumbar puncture. Dr. L. R. LEMPRIERE, the President, asked

[1] A summary of this work was published in the BRITISH MEDICAL JOURNAL for January 1st, 1927 (p. 34), under the title of "The spread of infection in schools and ships."

whether in an epidemic of influenza a mild case of poliomyelitis might be overlooked. Dr. WILLIAM DUNN (Uppingham) asked why lesions should sometimes produce a transient paralysis which got better, and sometimes the absolute death of the neurons and a lasting paralysis. Dr. Dunn also objected strongly to the interference of the Ministry of Health, and the extremes to which the requirement to make returns was sometimes pursued. He asked how many officers at the Ministry of Health had ever seen a case of acute poliomyelitis. The PRESIDENT said that in conversation with Sir George Newman it was made clear that the Ministry would do no more than tender advice. No question of authority could come in at all; the headmaster and the council of the school remained absolutely in control. Dr. DUNN, however, was doubtful as to the position of a school which was disbanded against the advice of the Ministry of Health.

Dr. ELWIN NASH asked how it was that epidemics which decimated certain districts of America differed from those experienced in this country. Dr. J. GRAHAM FORBES asked whether the meningitic type of the malady was followed by a definite paralysis; also whether the virus that Flexner described in 1908, and which was subsequently confirmed by Levaditi at the Pasteur Institute, was really the virus in poliomyelitis. Dr. W. ATTLEE referred to the difficulty of one or two abortive cases occurring in a big school. Ought the medical officer to take steps to find the carriers, and what should those steps be? Dr. J. A. H. BRINCKER said that when going into the history of many of the relapsing cases it had always struck him that there was a possibility that these had been abortive cases, and that on account of the fact that little or no attention had been paid to them they got the opportunity for reinfection, which was usually more severe.

Dr. COLLIER, in his reply, said that at present there were no practicable means of detecting a carrier, apart from lumbar puncture. Cases of poliomyelitis, especially abortive cases in the early stage, were often diagnosed as influenza. When there were no definite nervous signs he did not know any means of distinguishing, nor would he say that lumbar puncture would of necessity distinguish. The mild case of poliomyelitis affecting the back and giving rise eventually to spinal curvature was often overlooked. The only way to detect it in the acute stage was by a careful examination of the trunk reflexes, and in the upper thoracic region that was most difficult. As to the pathology of the disease, there had been much controversy. It was held for a long time that there was nothing but an inflammation, but it was now shown that while the infection produced an inflammation it also produced a paralysing poison. In monkey poliomyelitis derived from man the inflammatory lesion was seen not very often, the degenerative lesion of the cells was seen frequently, so that it was quite certain there was a lesion besides the inflammatory one. He had been asked with regard to the difference between epidemics. The comparatively mild epidemics in this country, especially in towns, differed from those which occurred in Sweden and other places for the reason that in a country where poliomyelitis was always endemic there were many carriers all the time, and therefore a much "salted" population. The herd was relatively immune. The worst epidemics had always been in sparsely populated country communities. As to whether the meningitic type of the disease left paralysis in its train, this was not usually the case. The meningitic type suggested an inflammation more within the skull and involving the meninges particularly, but there was no reason why in the meningitic type there should not be a lesion also at a distance which would produce paralysis. With regard to the cerebro-spinal fluid and its cells, nothing could be gathered from the nature of the cells with any certainty; there were surprising variations in different cases. Flexner's work on the virus had been completely verified, especially by work in Paris and Vienna, and in Japan, and he thought it might be taken that the pathology and bacteriology of the disease were settled. One speaker had suggested that relapses followed abortive cases. That was not his experience. He had never found an abortive case showing relapse. All the relapses he had seen had been after cases of considerable severity, and the abortive case and the relapsed case seemed a little contradictory.

DISCUSSION BY THE MEDICAL SOCIETY OF LONDON.

AT a meeting of the Medical Society of London held on February 7th, with the President, Sir HUMPHRY ROLLESTON, in the chair, a discussion was held on poliomyelitis.

Dr. F. M. R. WALSHE, in opening, enumerated the many difficulties associated with anterior poliomyelitis, which was, he said, a disease of great responsibilities for the medical attendant. The disorder was essentially an acute specific fever which might or might not proceed to invasion of the central nervous system. In epidemics many so-called abortive cases occurred, amounting to upwards of 50 per cent., in which recovery took place without paralysis. The disease as it ordinarily appeared could be divided into three phases. There was first the stage of general infection, varying from a few hours to three or four days. The reaction might be slight or very brisk; usually the temperature rose to 101° or 103°, the child showed general malaise, and certain local symptoms, which were generally gastro-intestinal, tonsillar, or coryzal in nature, were present. The second stage represented invasion of the subarachnoid or meningeal region, and varied in its time of appearance and in its intensity. It was characterized by fever, headache, pains in the back, rigidity of the spine, and sometimes tremor of the limbs. There might even be opisthotonos. The cerebro-spinal fluid was now usually under pressure with increase in the cells, polymorphonuclears in the early stages giving place to lymphocytes later, with increased globulin but normal glucose and chlorides. Recovery might occur even at this stage, or more usually the third phase with paralytic phenomena developed. Paralysis appeared suddenly, as a rule was maximal at its onset, and might rarely be ascending or appear to move from limb to limb. A generalized slight weakness might occur, and the nature of the malady was then frequently overlooked. Pain was often present and might be very intense and widespread. It was his (Dr. Walshe's) experience that tender muscles in the early stages frequently indicated the earliest recovery. Diagnosis in the pre-paralytic stage consisted in recognizing the signs of subarachnoid involvement. Treatment in the pre- and post-paralytic stage was distinct. In the former, where the time was often limited, only one drug appeared to have any value, and that was hexamine, which ought to be used in massive doses with alkalis. The serum of convalescent patients contained immune bodies; it should be used intrathecally and also subcutaneously and intravenously, the cerebro-spinal fluid being drawn off freely and serum given in doses of 10 to 15 c.cm. by the gravity method. Since the serum of human convalescents alone was available, this method was unreliable. The patient should be isolated and all excretions and secretions treated as infective for three weeks after fever had disappeared. The value of antiseptic gargles was problematic. The treatment of paralysed muscles involved certain general principles. In the acute stage rest and prevention of deformities alone should be attempted, massage and electricity being definitely harmful. The muscles should be placed in a position of physiological rest. Various methods of doing this were advocated, but the age, condition of the child, and the amount of pain present had all to be considered. In the pain-free convalescent period more active measures could be employed. Massage was useful in a restricted field, but electricity was of doubtful value and might be harmful. Re-education of the muscles was most important, and each patient had to have a scheme which was revised from time to time. The danger of stretching paralysed muscles was probably overestimated. Dealing next with the etiology of the disease, Dr. Walshe described its seasonal and age incidence. He stated that the incubation period averaged three to four days, and infection occurred by human borne contagion through the naso-pharynx, both sufferers and healthy carriers being responsible. The virus usually disappeared in three weeks, and there was no evidence of the existence of chronic active carriers. Natural resistance certainly occurred, and it was possible that many children suffered from an abortive form of the disease and became immune. Dr. Walshe quoted some general work on epidemiology, showing its application to poliomyelitis, particularly as to "bed to bed"

infection, as occurred in other infective fevers. He discussed the recent epidemic in this country, and pointed out that both the policies adopted—that of keeping children at school and that of sending them home—had certain objections, but local conditions must be a guide.

Professor J. McINTOSH gave a short account of the more recent work on the etiology and pathology of acute anterior poliomyelitis. He stated that the consensus of opinion [illegible] nce alone was that poliomyelitis was a entity. In the *post-mortem* exam- case some parenchymatous degeneration of the internal organs was found associated with a general enlargement of the lymph glands, including those of the intestinal canal, and congestion with minute haemorrhages in the grey matter of the spinal cord. Summarizing the histological lesions, Professor McIntosh described the typical perivascular infiltration in the grey matter of the cord, the cells being principally lymphocytes, with a small number of larger cells with a clear nucleus, while plasma cells were rare. Degeneration of the ganglion cells of the cord was a marked feature, with neuronophagia and complete disappearance of the cell. Haemorrhages were also a marked feature. All these changes indicated an infective origin for the disease, but bacteriological investigation of the malady proved entirely negative. At the same time, however, the disease was successfully transmitted to monkeys for the first time by Landsteiner and Popper in 1909, and this had been confirmed repeatedly. Professor McIntosh then described his own successful experiments with Dr. Turnbull, stating that the experimental disease produced in monkeys was in every respect comparable with poliomyelitis in children, with an average incubation period of nine to ten days, followed by high temperature, weakness and trembling in the limbs, and paralysis usually appeared within twenty-four to forty-eight hours in the lower limbs, and tended to spread upwards. This experimental work revealed that the virus of the disease belonged to the filter-passing group of organisms, and was very resistant to certain external influences and agents, such as drying; it had been kept in an ice-chest for weeks, while 50 per cent. glycerin, and even 5 per cent. carbolic acid, failed to destroy it. On the other hand, the virus was rapidly destroyed by 1 in 1,000 potassium permanganate, or 1 in 100 hydrogen peroxide. Experiments showed that however the *material was inoculated* in monkeys, the same disease was always reproduced, and intracerebral inoculations generally proved most successful. The virus appeared to have a special predilection for the grey matter of the cord, and of the tissues outside the nervous system practically only the lymphatic system contained virus. Experimentally the naso-pharynx had been shown to be the chief site of penetration of the virus, although some observers had favoured a gastro-intestinal route. The secretions from the naso-pharynx and urine or faeces appeared to be infective in many cases, even in carriers and abortive cases, which was an important point in epidemiology. Clinical evidence had been brought forward to show that abortive cases and carriers could spread the disease, probably by the virus present in the tonsils or pharyngeal mucus. No satisfactory evidence had yet been brought forward to show that biting insects played any part in the spread of the disease. The *mucus* of the naso-pharynx might contain the virus for as long as seven weeks after an attack of poliomyelitis. Animals which had recovered from paralysis or from abortive attacks were immune to a second inoculation, which was in keeping with clinical observations, and the blood serum of convalescents would destroy the virus *in vitro*. This convalescent serum had been used for therapeutic purposes with apparent good results, and attempts at vaccination in monkeys with killed or attenuated virus had also met with considerable success. Professor McIntosh then described some of the applications of the pathological work to prophylaxis against poliomyelits by gargles and sprays for the naso-pharynx, combined with complete isolation of cases and contacts. He concluded by mentioning certain diseases of the nervous system which were not clearly distinguished from poliomyelitis, instancing Werdnig-Hoffmann progressive spinal muscular atrophy, Landry's paralysis, and toxic polyneuritis.

Sir THOMAS HORDER first referred to some points in a paper by Dr. Mervyn Gordon which had been prepared for the meeting, showing lantern slides to illustrate certain aspects of the histological lesions in the cord. One case of clinically diagnosed Landry's paralysis showed typical lesions of anterior poliomyelitis. The two essential features of the disease in its histological picture appeared to be neuronolysis and neuronophagia. Coming next to his own paper, the speaker dealt first with some difficulties in diagnosis under two aspects. There was first the diagnosis of poliomyelitis from diseases without specific infection of the nervous system, but in which nervous symptoms were present—as, for example, meningism in pneumonia or influenza, and secondly, the diagnosis from cases with definite infection of the nervous system, such as encephalitis, acute infective polyneuritis, and cerebro-spinal fever. A "catarrhal" group of diseases, influenza, *Micrococcus catarrhalis* infection, whooping-cough, and measles were all examples of acute pyrexia in which nervous symptoms might be present, and he thought it important to beware of such terms as "cerebral influenza" or "neuritis complicating influenza." He had seen cases of poliomyelitis occurring in a boarding school side by side with influenza in the epidemic of 1918, and recently he had seen acute encephalitis occur in the fourth week of whooping-cough. He differed from Dr. Walshe as to the way in which the virus acted, preferring to think of the nervous system infected as a whole, with attenuation of the virulence as deeper structures got involved in some cases. Dealing with some early symptoms, he had found retention of urine in some cases in young adults. Pain, especially focal at the onset, was valuable in diagnosis, and tenderness of muscles also helped. It was important to realize that poliomyelitis was not a purely "motor" disorder.

Dr. JAMES COLLIER dealt with several points which had been raised. He thought that it was an error to describe a leucocytosis in the blood, and in the cerebro-spinal fluid the nature of the cells was very variable, polymorphonuclear cells or lymphocytes predominating at all stages of the disease. He stated that the virus present in the throats of sufferers had been used experimentally to infect monkeys, but there was no proof that it would infect humans. The carrier was very important, and might be completely healthy. In his experience he had never seen a patient infect other children in hospital, and he thought that possibly the disease was transmitted only by carriers. He disagreed as to poliomyelitis not being a very infective disease, quoting certain epidemics to illustrate this. Many epidemics were probably preceded by a "carrier epidemic."

Dr. A. F. HURST discussed the treatment of the disease by hexamine, adding that 100 or even 200 grains of hexamine could be given three times a day if the urine was kept alkaline by adequate doses of potassium citrate.

Dr. M. O. RAVEN (Broadstairs) raised the question of abortive cases and the difficulties of diagnosing a "carrier epidemic." Cases had occurred in Broadstairs dotted all over the town where carriers could not be blamed, and he believed that flies and dust might still have something to do with the spread of the disease. He mentioned some experimental work in which macerated flies had been used to infect animals.

Mr. R. C. ELMSLIE said that in a large proportion of the cases seen by a surgeon the early stages of the disease had been undiagnosed. The resulting paralysis had to be distinguished from certain local conditions—as, for example, arthritis of the hip-joint, in which muscular tenderness and resistance to movement might be found without any history of febrile disturbance. He thought that institutional treatment would be of great benefit, because by the study of cases segregated in a special institution a lot might be learnt about the disease, and because better results could be obtained if children could stay in the same institution for even, say, five years if necessary for the complete cure of the resulting disabilities. Unfortunately, authorities did not appear willing to take patients until three months after the acute stage for fear of infecting attendants or other children.

THE TREATMENT OF LEPROSY.

AT the Royal Society of Medicine on February 2nd the Sections of Tropical Diseases and Parasitology, Dermatology, and Therapeutics and Pharmacology united for a discussion on the treatment of leprosy. Dr. R. T. LEIPER, president of the first of these Sections, was in the chair.

Dr. J. M. H. MACLEOD detailed his experience of recent methods of treatment at St. Giles's Homes for British Lepers, the only leper colony in this country, where there was accommodation for twelve cases. He said that fortunately leprosy had long ceased to be indigenous in these islands, but a few cases still existed, the exact number being impossible to estimate in the absence of compulsory notification. The majority were British subjects who had come home from abroad suffering from the disease. Only very rarely had infection started in this country by close and prolonged contact with lepers from abroad; he had under his care three such patients, and knew of one other. Consequently it was inadvisable even here to belittle the danger of the spread of the disease, and not to take effective measures against it. Unlike protozoal diseases, such as syphilis and trypanosomiasis, where drugs like arsenic, mercury, and antimony were specifics, in bacillary diseases, so far as he was aware, no drug had yet been proved to have a specific action. Perhaps leprosy might be an exception, but in his experience it could only be said that, as in tuberculosis so in leprosy, segregation and treatment on general hygienic principles were of more importance in enabling the patient to resist the invasion of the bacillus and in hastening the arrest of the disease than any known form of so-called specific medication. He suggested as points for discussion the question whether any drugs now employed, including the chaulmoogra or hydnocarpus oils, had a specific action on the disease, what was the value of vaccines in the treatment, and what were the best conditions of climate, altitude, and mode of life for promoting arrest.

Dr. J. H. SEQUEIRA entered a plea for the careful consideration of "protein shock" as the real cause of the beneficial results in a number of so-called cures. He described how in 1911 investigations were made in his clinic as to the cause of "salvarsan fever"—the rigors and rise of temperature which followed, in the early days, the injection of a dose of salvarsan dissolved in 100 c.cm. of presumably sterile solution. To determine whether the reaction was due to the salvarsan or to the medium, a number of patients were injected with the "sterile" solution only. One subject so submitted was an advanced case of maculo-anaesthetic leprosy. Following the injection he had rigors and high temperature, and the same results followed a second and a third injection, but after the second injection the very extensive eruption began to fade, and after the third injection it disappeared entirely. This man had attended his department at regular intervals for the past sixteen years, and there had been no recurrence. The anaesthetic areas were less, an atrophy of the muscles persisted, a perforating ulcer had been healed, the disease had been absolutely stationary for years, but he did not claim the case as a cure.

Dr. GEORGE PERNET, in dealing with a fair number of lepers, had found that the best thing to give, especially in the nodular type, was chaulmoogra oil. It was not a specific by any means, but the fact should be borne in mind that when, as happened some years ago, the crop of *Taraktogenos kurzii*, from which chaulmoogra oil was derived, was a failure, and other oils were substituted in the commercial market, many disappointments in treatment resulted. He had treated lepers also with mercury perchloride, though with no very great satisfaction; but whenever any new method was employed, whether it was the effect of suggestion or not, the cases seemed to improve a little. When Koch's original tuberculin came out, Radcliffe Crocker, with whom the speaker was working, applied it in leprosy, but the result was the breaking out of a very great number of small nodules all over the patient's skin. He suggested that thyroid might be tried, not in the hope of finding a specific, but because it would assist the general metabolism.

Dr. G. C. Low said that there was no specific cure for leprosy at present. Probably in tropical medicine the nearest approach to a complete specific was the action of antimony in kala-azar. Chaulmoogra oils and their derivatives were not specific, but acted probably by improving the nutrition of the body. He thought that there was hope for the future in "protein shock," which, however, was no new thing; he could remember in 1893 the suggestion being made that a leper should be given thin beef extract to induce protein shock. Some of those present might have followed the correspondence in the BRITISH MEDICAL JOURNAL on Dr. Graham Little's case (December 4th, 1926, p. 1034; 11th, p. 1141; and 18th, p. 1195), the good result in which, in the speaker's opinion, must be set down to protein shock. It was a matter that should be investigated further.

Mr. T. A. HENRY, D.Sc. (Director, Wellcome Research Laboratories), gave an account of the chemistry of the chaulmoogra and hydnocarpus oils. The organic chemist, he said, had not until recently given much attention to the fixed oils, mainly because they were simple in their structure and did not lend themselves to the protean changes in which he specialized. Several of these oils had an interest for the leprologist, because they did exert some effect in leprosy, but the chaulmoogra and hydnocarpus oils were the most effective of the series. It had been assumed, and apparently with good reason, that the action of these oils in leprosy was due to certain peculiar acids, which had not been found in any plant outside the natural order *Flacourtiaceae*. Most of these oils contained both chaulmoogric and hydnocarpic acids, and it seemed possible that the activity was due to the hydnocarpic acid alone. Unfortunately, this acid had not yet been found by itself in any of these oils, and its separation from associated chaulmoogric acid in the large quantities required for clinical trials was not easy. The speaker thought, however, that some work by Sir Leonard Rogers pointed to the explanation that to be useful the acids must be liquid or nearly liquid at the body temperature, and if that was so it would probably be found that a mixture of the two acids was essential. It was quite likely that the now common practice of injecting chaulmoogra and hydnocarpus oil esters mixed with olive oil was advantageous, because it lowered the melting point of the fatty acids, which were no doubt liberated from the mixture in the body. The speaker was not very hopeful with regard to the possibility, by a synthesis of a series of acids of this type, of arriving at something more effective than the natural acids, and it was perhaps in other directions that an improved and speedier treatment of leprosy might be found. There was some hope in a series of mercury derivatives, which had the advantage that they could be used in combination with treatment by hydnocarpus oil.

At this point in the discussion three communications from workers abroad were presented by Sir LEONARD ROGERS.

Dr. ERNEST MUIR (School of Tropical Medicine, Calcutta) wrote that there was no specific for leprosy. There was a line of treatment, however, which would cause the permanent disappearance of all active signs of the disease in early cases, though if a marked reduction in the general health of the patient occurred later there was always the possibility of a relapse. This line of treatment consisted of the following: (1) treatment of any accompanying disease; (2) rectification of diet; (3) gradually increasing exercises; (4) use of special drugs, the injection of hydnocarpus oil and its preparations being the most important; (5) external applications; (6) surgical intervention when necessary. Vaccines were useful, especially in certain cases and in the third stage of the disease, given intravenously, but the action was more of the nature of anaphylactic shock than specific. The real test of the efficiency of any special treatment for leprosy was its effect in the first and second stages, and it was in these that hydnocarpus oil was so useful.

Dr. H. W. WADE (chief pathologist, Leper Colony, Philippine Health Service) forwarded a description of the general plan of the antileprosy campaign in the Philippines. Cases in which there was hope of success in treatment were kept in regional treatment stations of the hospital or asylum type under close supervision. Those unfavourable for effective treatment were transferred to another colony where they could lead more

normal lives. In 1927 there was to be inaugurated a system of searching out and dispensary treatment of clinically positive but bacteriologically negative cases. Mixed chaulmoogra ethyl esters were the principal preparations used in treatment, for the most part with iodine added, to reduce irritation. Weekly intramuscular injection was the almost universal rule. These modern treatment methods appeared to be particularly effective in early cases. The results obtained in the Philippine Islands during the last few years showed that a not inconsiderable proportion of advanced cases (probably 15 or 20 per cent.) could be "apparently cured" if treated intensively under proper conditions—a noteworthy advance, though not particularly encouraging to anyone treating a small group of unselected cases.

The third communication read by Sir Leonard Rogers was from Dr. ISABEL KERR (Dichipalli Leper Institution, India), who said that most cases of early leprosy treated by oils of the chaulmoogra series did well. In the second stage treatment had to be protracted, as small doses of the drug only could be given for fear of aggravating the disease, but in the third stage the drug could be pushed.

Dr. R. G. COCHRANE (medical secretary, Mission to Lepers) said that he had seen some 10,000 cases of leprosy in India and the Far East. He considered that during the early or invasion stage the treatment of cases by "protein shock" was decidedly harmful. In the second stage, where there were raised rashes and numerous nodules, "protein shock" had a definite value in treatment. After seeing various methods of treatment in India he had come to the conclusion that the most effective remedy and the cheapest—and, after all, in dealing with the very large number of cases cheapness was a consideration—was hydnocarpus oil combining 4 per cent. creosote. This seemed to do the maximum amount of good in leprosy in all stages.

Dr. E. A. O. TRAVERS spoke from his experience of personal charge of a leper asylum in the Malay Peninsula, where the average number of patients was about 400. The main treatment he had carried out had been to give the powdered nut of the hydnocarpus tree. It was possible that in the extraction of the oil some valuable constituent was left behind. To give the whole nut was a very popular method of treatment among the Chinese, and in an old Chinese *Pharmacopœia* he had found the chaulmoogra nut recommended as a treatment for leprosy. The medicament was palatable and inexpensive, and could easily be taken by women and children as well as by men, which was not the case with the injections, though if a case did not improve sufficiently quickly he had practised injection as well.

Dr. JAMES HASSON (late chief surgeon, Edith Cavell's Hospital, Alexandria) disagreed with the statement made by Dr. Muir and by other speakers that the results following vaccines were due to "protein shock." He regarded the treatment as absolutely specific in its action.

Dr. FREDERICK HALL (late district medical officer, Fiji) declared that there was no specific cure for leprosy. Many of the treatments given in the past had been harmful. All treatments that produced sensitization or reaction were harmful. Chaulmoogra oil and similar treatments all did good so long as they were given only to stimulate the patient's powers of resistance. Exercise and massage acted in the same way. In the occasionally dramatic results seen in a well organized hospital there had probably been treatment of intercurrent disease, the nourishment of body and mind, the prevention by cleanliness of fresh infection, and the promotion of an atmosphere of recovery.

Dr. MACLEOD, in replying, said that there seemed to be general unanimity amongst the speakers that there was at present no specific cure for leprosy, and that chaulmoogra and hydnocarpus oils, though they could not be called specifics, were of some value in promoting the arrest of the disease. He rather joined issue with some speakers in what had been said about protein shock. He had seen marked improvement after the injection of milk albumin and the reaction produced by it, also after an injection of Koch tuberculin, though in other cases he had seen rather the reverse, perhaps because they were taken at the wrong stage.

Sir LEONARD ROGERS, who also replied, referred to his work in using sodium salts of fractions of the chaulmoogric and hydnocarpic acids, and said that the only drawback had been the irritating action of the customary injections. This difficulty had now been overcome, and the injections, whether made intramuscularly or by an infiltration method as practised by Dr. Muir, could be absolutely painless. Instead of the 3 per cent. solution hitherto employed, a 1 per cent. solution was used, and was just as active, but without the irritating quality. This modified preparation was now being tested in Calcutta and in the Philippines and in other places where he had sent it. On the general question Sir Leonard Rogers referred to the great improvement in the outlook on leprosy during the last decade, and the fact that the advances made were due to English-speaking investigators, among whom he desired to pay a special tribute to the Americans.

FILTRATION OF HERPES VIRUS THROUGH COLLODION MEMBRANES.

AT a meeting of the Section of Pathology of the Royal Society of Medicine on January 18th Dr. S. P. BEDSON described an experimental investigation of the filtration of herpes virus through collodion membranes.

Dr. Bedson said that it had been stated by Levaditi and Nicolau (1923) that the virus of herpes febrilis, as well as other so-called filterable viruses, passed through collodion membranes which, under similar conditions of filtration, held back all the haemolysin in a rabbit antiserum and, entirely or in greater part, complement and diphtheria and tetanus toxin. These membranes allowed peptone and amino-acids to pass through freely. The filtrates were tested chemically for the presence of protein, which was found to be present in a concentration of 1 in 1,000, how constantly was not stated. These authors had employed sacs made from a collodion having a composition of 6 per cent. nitrocellulose in equal parts of 95 per cent. alcohol and ether. The collodion sacs were sterilized at 110° C. for ten minutes, and filtration was carried out with a positive pressure of 10 to 12 cm. of mercury. It would appear that the experiments were intended to demonstrate that these viruses, including the virus of herpes, were of smaller dimensions than protein molecules, but since the collodion filters employed by these workers allowed some protein to pass, it was obvious that no conclusions could be drawn as to the relative size of virus particles and protein molecules unless the quantity of both was determined before and after filtration. This they had not done. Working with herpes virus, Dr. Bedson had attempted to approach the question quantitatively. Filtration was carried out with a Seitz filter in which the Seitz filter disc was replaced by one of collodion. Collodion membranes were made of varying degrees of permeability by increasing the percentage of alcohol in the solvent of the nitrocellulose and by soaking the membranes in varying concentrations of alcohol from 0 to 90 per cent. Filtration was performed at a pressure of from 200 to 300 mm. of mercury. The herpes viruses used for filtration were guinea-pig passage viruses, and the amount of virus present before and after filtration was estimated by making a series of dilutions and inoculating each dilution on the scarified epilated hairy skin of the guinea-pig. The amount of protein present before and after filtration was determined by means of a precipitating serum for guinea-pig serum. The membranes found to allow the greatest quantity of protein to pass were those made from a collodion containing 4 per cent. nitrocellulose in 75 per cent. alcohol and 25 per cent. ether soaked in water only, and those least permeable from a collodion containing 4 per cent. nitrocellulose in 50 per cent. alcohol and 50 per cent. ether and soaked in alcohol for twenty-four hours. None of these membranes allowed the herpes virus to pass through in sufficient quantity to infect guinea-pigs when the filtrate was inoculated into the plantar skin or rubbed into the scarified and epilated hairy skin. Even those membranes which allowed 1 part in 400 of the protein present in the unfiltered virus to pass through the filter reduced the virus content of the filtrate below the least quantity required to infect a guinea-pig.

TREATMENT OF TRAUMATIC FACIAL PARALYSIS.

AT a meeting of the Section of Otology of the Royal Society of Medicine on February 5th a paper by Dr. E. FARQUHAR BUZZARD on the treatment of traumatic facial palsy was read.

It was stated that owing to the anatomical conditions no operative procedure at the site of the lesion was possible as a rule; treatment, therefore, could not follow the same lines as that for other peripheral nerves, though the general principles were similar. Where the lesion only caused a partial paralysis signs of recovery might be expected to appear in about three weeks, but in severe cases, where the paralysis was complete, recovery did not begin until the end of about four months. If at the end of that period there were no signs of recovery the outlook was serious. It was important to take measures to maintain the facial muscles in good condition and to provide the patient with an apparatus to prevent the paralysed muscles from becoming stretched and subsequently passing into a condition of post-paralytic contracture. Active co-operation on the part of the patient was important.

Cases illustrating the surgical treatment of facial paralysis by means of nerve anastomosis were shown by Mr. E. WATSON-WILLIAMS, Mr. LIONEL COLLEDGE, and Mr. C. GILL-CAREY.

Sir WILLIAM MILLIGAN commented on the rarity of facial paralysis in this country, owing to the care taken in operating and in after-treatment, compared with what he had observed in aural clinics on the Continent. He emphasized the importance of massage and electrical treatment of the facial muscles. A long period might elapse before the ear was healed and in a condition to allow an operation for nerve anatomosis to be performed. In a case of tuberculosis of the ear in a child this period had been seven years, during which unremitting care had maintained the nutrition of the facial muscles.

Mr. LIONEL COLLEDGE, in answer to a question by Mr. G. J. JENKINS, said that if no signs of recovery had appeared at the end of six months it was unlikely that the paralysis would improve; in the absence of any such signs at the end of twelve months, complete restoration was most improbable. Although cases of recovery after much longer periods had been reported, they were so rare that he thought a nerve anastomosis was justifiable if complete paralysis persisted more than a year. The two cases he had presented, however, showed that complete recovery of power and of the electrical reactions might occur in all the facial muscles after an interval of two years and four years respectively following anastomosis either to the hypoglossal or the descendens noni.

Dr. C. P. SYMONDS thought the long delay in recovery in some cases might be explained by functional disuse, and supported Dr. Buzzard in drawing attention to the importance of active participation in the treatment by the patient.

Diagnosis and Localization of Cerebral Abscess.

Dr. C. P. SYMONDS, in a paper on some points in the diagnosis and localization of abscess of the brain, said that severe headache, vomiting, drowsiness, and slowing of the pulse marked the occurrence of mechanical obstruction to the outflow from the ventricles with internal hydrocephalus, and were terminal symptoms. In the early stages there were fever, rapid pulse, general malaise, and anorexia, with intermittent headache. The localizing signs might be considered under three headings: (1) cerebellar, (2) left temporal, (3) right temporal. (1) Suboccipital headache was important, but it might be bifrontal or general. The finger-nose-finger test was the simplest method of examination. Falling away of the affected limb when support was withdrawn from beneath the outstretched hands was also useful. The other sign was nystagmus. The patient should be asked to look towards the side of the lesion, the spontaneous deviation occurring in the opposite direction. The quick component might be absent, so that the eyes slowly swung back towards the middle line. (2) In abscess of the left temporal lobe in a right-handed person the sign of outstanding value was aphasia. It might be necessary to show a patient a large number of objects to elicit this symptom. Thus only one or two out of a dozen objects might not be correctly named, but these failures were sufficient. (3) The other signs of temporal lobe abscess were common to both sides. The first was weakness of the opposite side of the face, mostly of the lower half, which might be present when the patient talked or smiled, but was less apparent when he showed his teeth at command. The second group indicated pressure on the pyramidal tract —absent or diminished abdominal reflexes, increased knee-jerks, with extensor or doubtful plantar response. The third sign was a defect in the visual field caused by involvement of the optic radiation, which at first swept downwards and forwards and extended well forward into the temporal lobe before it turned back beneath and around the lateral ventricle to reach the occipital cortex. An otitic abscess lying in the lower part of the temporal lobe was likely to affect the inferior bundle of the radiation, producing homonymous defect in the superior quadrants of the opposite fields. The cerebro-spinal fluid was clear, and contained a slight excess of cells, varying from 18 to 95 per cubic millimetre, mainly lymphocytes. A preponderance of polymorphs with diminution of chlorides and absence of sugar reduction was usually associated with meningitis, and indicated that the abscess was leaking into the ventricular system or the subarachnoid space. The paper concluded with an account of certain cases illustrating the diagnosis of superficial abscess in which the signs and symptoms were cortical in character, and also of localized non-suppurative encephalitis in which spontaneous cure might result.

In the discussion which followed Mr. SYDNEY SCOTT and Mr. G. J. JENKINS drew attention to the importance of avoiding lumbar puncture if possible, and only withdrawing small amounts of cerebro-spinal fluid should this proceeding be necessary in suspected abscess of the brain. The withdrawal of 5 c.cm. of cerebro-spinal fluid had been sufficient to cause sudden death.

RECURRENT PREGNANCY TOXAEMIA.

AT a meeting of the Edinburgh Obstetrical Society on January 12th, the President, Professor R. W. JOHNSTONE, in the chair, Dr. JAMES YOUNG read a paper entitled "Recurrent pregnancy toxaemia and its relation to placental damage."

Dr. Young said that in 1914 he had submitted evidence that the eclamptic phenomenon was caused by the absorption of the toxic elements rapidly elaborated in a mass of dying placenta. Since then it had been shown in other connexions that extremely toxic materials, such as histamine and tyramine, might be produced from disintegrating tissue. He had at that time described the placental lesion, and, as Strachan had shown recently, his general views had since been confirmed by Clemenz, McNalley and Dieckmann, Adair, Soli, and others. If the placental lesion extended over a considerable area of the organ it might cause immediate ending of pregnancy by abortion, premature labour, or accidental haemorrhage without toxaemia, but less marked damage might be consistent with continued life of the foetus, and, therefore, with the time necessary for the development of the toxic elements responsible for the eclamptic attack. Such a view was in harmony with the well known facts that no essential part of the eclamptic process was direct damage to the foetus, the life of which might be unharmed even in the most fulminating case, and that, on the other hand, a severe eclampsia might suddenly subside after the intrauterine death of the foetus and the consequent complete detachment of the placenta. Dr. Young brought forward new evidence derived from a study of 220 successive cases of toxaemia and accidental haemorrhage in parous women in the Edinburgh Royal Maternity Hospital. In eclamptic cases a recurrence of eclampsia or non-convulsive toxaemia was found in over 30 per cent. This was clearly an underestimate, because it did not allow for those cases in which the toxaemia occurring in the last pregnancy, for which the patient was admitted to hospital, was the first of a recurring sequence. In addition, in eclamptic cases there was a 40 per cent. tendency to the occurrence in

successive pregnancies of abortion, premature labour, accidental haemorrhage, or stillbirth. The morbid process resident in the patient and damaging the successive pregnancies might be "primary" or "acquired." In many of the damaged pregnancies of the sequence there was no toxaemia. It had long been known that this absence of toxaemia occurred in many cases of accidental haemorrhage. Toxaemia was present in only about 40 to 50 per cent., and even in patients who died as the result of the haemorrhage there might be no evidence of toxic changes in the liver and kidney. The toxaemia was an accident, and was apt to be intense in "concealed haemorrhage" in cases where the damaged placenta was retained within the uterus. Dr. Young showed that the same abortion—premature birth—toxaemia sequence occurred in this condition in 18 out of 55 cases, or 32 per cent. Dr. Young believed that the data indicated that the causes of eclampsia and the related toxaemia of pregnancy were to be found amongst the causes of abortion and premature birth, which operated by means of placental damage. Toxaemia was an accident occurring only in those cases in which, after the placenta was damaged, the abortion or premature birth did not follow soon enough or quickly enough. Dr. Young stated further that the recognition of the high incidence of recurrence in true eclamptic toxaemia, and, in eclamptic cases, of the considerable tendency to recurring abortion and premature labour, made necessary a revision of the views held regarding so-called "nephritic" toxaemia. It had been generally believed that there were two groups of late pregnancy toxaemia—the eclamptic or non-recurrent, and the "nephritic" or recurrent—but the distinction was now untenable. This statement did not, of course, apply to those comparatively few cases of kidney disease clearly acquired before pregnancy from such causes as scarlet fever, which were sharply marked off from the specific toxaemia in which the nephritis was secondary. Dr. Young believed there was now much evidence for the view that the late pregnancy toxaemias, whether eclamptic or "nephritic," had a similar origin in the diseased placenta, and that kidney damage in such cases was secondary and was often aggravated by successive toxic pregnancies. This was supported by his own investigations and by those of others, which indicated that chronic nephritis might succeed even one eclamptic attack.

Occipito-posterior Presentation.

Dr. DOUGLAS MILLER read a communication on the occipito-posterior position of the vertex. His paper was based on an analysis of 750 occipito-posterior cases, the majority of which had been delivered in the Edinburgh Royal Maternity Hospital. In all cases, except for the abnormal position, labour was uncomplicated by contracted pelvis or other major abnormalities and diagnosis of the posterior position was made or confirmed during labour. The cases were classified into the following four groups:

Group I.—Spontaneous rotation of the occiput to the front had occurred in 474—rather more than 60 per cent. This figure probably underestimated the frequency of anterior rotation, as the review necessarily omitted cases admitted late in labour, in which forward rotation of a primarily posterior position might have already occurred. Where anterior rotation took place the average duration of labour was greater than in primary anterior positions by two and three-quarter hours in primigravidae and by one and three-quarter hours in multiparae. In 51 cases forceps delivery was ultimately necessary because of foetal distress or rigidity of the pelvic floor.

Group II.—In 88 cases the child was born spontaneously face to pubes, and in 9 cases the infant was the second of twins. In the majority of the remainder the children were small or the vaginal orifice abnormally lax.

Group III.—In 48 cases (6.4 per cent.) the head was seriously delayed at the inlet of the pelvis. In approximately two-thirds of these manual rotation of the head was performed. This manœuvre was as a rule followed by forceps extraction, although in many cases no further assistance was required. Rotation of the head was effected by means of forceps in 5 cases. Internal version was performed in 12 cases, and gave much less satisfactory results. It was added, however, that in the majority of cases this operation was not one of election, but had been employed as a last resort after labour had become seriously prolonged. Craniotomy was performed in 2 cases in which foetal death had already occurred.

Group IV.—In 140 cases arrest of the head with the occiput posterior occurred at a low level in the pelvis. Manual rotation, followed by spontaneous or forceps delivery, was the treatment adopted in rather more than half of these cases. In about 25 per cent. rotation was effected by forceps. Extraction of the child face to pubes was employed in a small number of cases of severe impaction, while in 8 cases in which delivery of a living child was considered impossible, craniotomy was performed.

These different methods of dealing with persistent occipito-posterior cases were shortly discussed, and it was shown that a comparison of the tabulated results was definitely unfavourable to forceps rotation. In emphasizing the importance of diagnosis, Dr. Miller pointed out that in the majority of cases it was possible to foresee at an early stage in labour whether forward rotation was likely to occur or not, by careful abdominal and vaginal examination or by the occurrence of such signs as were shown in the following table.

	No. of Cases in which Noted.	Termination: Mal-rotation or Non-rotation.	Spontaneous Forward Rotation.
Early rupture of membranes...	197	145 (74%)	52 (26%)
Delayed engagement of head...	139	107 (77%)	32 (23%)
Foetal heart heard both in flank and in opposite anterior lower quadrant	103	78 (76%)	25 (24%)
Normal engagement and rupture of membranes at or near full dilatation of os	332	33 (10%)	299 (90%)

Dr. Miller remarked that dystocia was greatest and morbidity highest in the persistent posterior case in which assistance had been unduly delayed until serious impaction had occurred, and the suggestion was made that in the restricted group of cases in which clear indications of faulty flexion were present, rotation of the head and body of the child might with advantage be performed at or near the commencement of the second stage of labour. This proposal of early intervention did not in point of fact run counter to the policy of conservatism so generally applicable in the management of labour; for against a manœuvre which was comparatively simple and safe when done early there had to be placed the high probability of formidable and difficult intervention after the mother had become exhausted by hours of suffering and fatigue, and the foetal life was at a low ebb.

DYSENTERY IN ABERDEEN.

AT a meeting of the Aberdeen Medico-Chirurgical Society on January 13th, with Dr. THOMAS FRASER, the vice-president, in the chair, a paper entitled "A note on some cases of dysentery in Aberdeen" was read by Dr. ROBERT RICHARDS.

Dr. Richards classified bacillary dysentery under the three main headings: (1) endemic, occurring in tropical and subtropical countries; (2) epidemic, usually occurring in minor form in local outbreaks in this country; and (3) sporadic, occurring in strictly isolated cases where the two previous types were rare or unknown. He referred to the large amount of work which had been done in infantile diarrhoea and the curious differences with regard to the causative organisms. American investigators had found that many cases were due to the *B. dysenteriae* of Flexner, the figures of the Boston floating hospital being 75 per cent. and in Baltimore 80 per cent. The latest figures for Britain were those of Nabarro, who recorded that in 13 cases out of 150 from the Great Ormond Street Hospital for Sick Children the dysentery bacillus was found. Dr. Richards's first case was a boy, aged 7, sent to the Royal Hospital for Sick Children with a diagnosis of intussusception. Before admission to hospital he had been ill for two days with vomiting, purging, and a temperature of 101.2° F., and he passed large quantities of blood and mucus. On admission he had a pinched, anxious expression; the abdomen was retracted and tender, but no tumour was felt. Rectal examination caused severe tenesmus with the

expulsion of some blood and mucus. A tentative diagnosis of ileo-colitis, or dysentery, was made, but in view of the doctor's statement that he had felt a tumour the abdomen was opened. No tumour was found, but the colon was thickened and swollen, and the appendix was also swollen and congested; there was great enlargement of the mesenteric glands. The case was then treated, as one of acute dysentery, with magnesium sulphate and the condition rapidly cleared up. The finding of *B. dysenteriae* Flexner confirmed the diagnosis. In this country the diagnosis of intussusception in such cases was not unlikely, but on rectal examination a distinct difference was apparent. In dysentery the tenesmus set up was very great and the examining finger was forcibly ejected, being followed by the passage of blood and mucus, whereas the rectum in a case of intussusception was large and roomy, unless a tumour was felt, and, in addition, no tenesmus was set up. The next three cases described were children aged 8, 4, and 5, all of whom showed typical dysentery symptoms, and in two cases *B. dysenteriae* Flexner had been isolated. The stool examination in case No. 3 was twice reported as negative for dysentery organisms, but this might have been due to delay in transmitting the specimen. The child, aged 4, had practically the same symptoms, but the causative organisms belonged to the food poisoning group, the *B. aertrycke*. An interesting feature in this case was the fact that three years later he was seen with a painful left knee, evidently a referred pain from the hip-joint; where all movements were restricted and a certain degree of fixed flexion was present. The temperature was 100° F. and the pulse correspondingly rapid. An *x*-ray examination was negative. On the same afternoon the patient became sick and developed diarrhoea accompanied by tenesmus and the passage of blood and mucus in the stool. A diagnosis of dysentery with toxic arthritis was made, and the finding of the Sonne bacillus confirmed this. Further confirmation was afforded by the clearing up with saline treatment of both conditions. In Dr. Richards's belief there was no previous record of such metastatic joint symptoms from Sonne dysentery, although arthritis was a common complication of both Shiga and Flexner dysentery in Macedonia. A further series of three cases of Sonne dysentery was described. Dr. Richards thought that true dysentery was not so rare among the general population as was usually stated. An outline was given of the treatment with magnesium sulphate which had been found to be almost specific in dysentery cases.

SPLENECTOMY AND BANTI'S DISEASE.

AT a meeting of the Section of Pathology of the Royal Academy of Medicine in Ireland, on December 17th, 1926, Professor WIGHAM in the chair, Dr. A. HALPENNY reported a case of Banti's disease treated successfully by splenectomy.

Dr. Halpenny said that a man, aged 30, was admitted to hospital with jaundice and weakness. The skin and sclerae were deeply jaundiced, the hepatic dullness in the middle line extended almost to the umbilicus, and the lower pole of the spleen was palpable two fingerbreadths below the ribs. The patient's weight was 8 st. 9 lb. The cardio-vascular, respiratory, and nervous systems were normal. The urine gave a positive benzaldehyde test for excess of urobilinogen. A blood count showed red cells 3,260,000 per c.mm., haemoglobin 70 per cent., and white cells 8,900 per c.mm., with 61 per cent. neutrophile polymorphonuclear leucocytes, 5 per cent. eosinophiles, and 34 per cent. lymphocytes. Splenectomy was performed, and the liver was found enlarged and cirrhotic; there was some fluid in the peritoneum. The patient had a moderate temperature for four days, after which he made an uneventful recovery. One month later the blood count was: red cells 3,880,000 per c.mm., haemoglobin 75 per cent., and white cells 11,500, of which 65 per cent. were neutrophile polymorphonuclear leucocytes, 5 per cent. eosinophiles, 29 per cent. lymphocytes, and 1 per cent. mast cells. The jaundice gradually decreased after the operation, and had almost disappeared when the patient was discharged a month and a half later, feeling very much stronger. The spleen weighed 985 grams. The cut surface showed small white areas which proved to be composed of fibrous tissue, the capsule was thickened, and sections showed general thickening of the reticulum with hyperplasia of the Malpighian bodies. There was an abnormal density of the whole splenic tissue and engorgement of the sinuses with blood. The walls of the sinuses contained a large amount of blood pigment.

Professor T. G. MOORHEAD described a case of Banti's disease, which had greatly benefited by removal of the spleen. The special interest of the case was that it occurred in a child, aged 6½ years, whose father had suffered from a similar condition. The father had his spleen removed some years previously and was now in perfect health. As a rule Banti's disease first showed itself in adult life, and it was only very rarely that a familial tendency had been recorded. Before the operation the child was very anaemic, the haemoglobin 50 per cent., the red blood cells somewhat reduced, and nucleated red blood cells were present. Two months after the spleen had been removed the haemoglobin reached 85 per cent., the red blood cells were increased, and nucleated red cells had disappeared. Prior to the operation the differential white blood count was practically normal, but after it the differential count showed 60 per cent. of lymphocytes.

Dr. J. LAIT demonstrated the spleen, which was enlarged and very congested, the Malpighian bodies standing out very prominently. The whole of the cut surface was thickly studded with small irregularly shaped masses, yellowish brown in colour, and from four to five times as large as the Malpighian bodies, which were hypertrophied. The small brownish masses were composed of fairly dense fibrous tissue; among the fibres were unstained translucent fibres not unlike degenerated muscle fibres in appearance, and numerous multinucleated giant cells. The masses contained pigment which gave the iron reaction, and calcification was demonstrated by von Hona's method. Dr. Lait had found similar appearances in splenomegalies associated with syphilis and myelogenous leukaemia. He had come to the diagnosis of Banti's disease mainly by a process of exclusion.

Cerebral Haemorrhage and New Growth.

Dr. A. R. PARSONS gave an account of two recent deaths due to cerebral disease. A man, aged 52 years, was found unconscious in the street; he was bathed in perspiration, and there was extreme rigidity of the lower extremities. The pupils were small, but equal in size, and the blood pressure was 240 systolic, 110 diastolic. He lived for just thirty hours after admission. Dr. Parsons considered the case to be one of decerebrate rigidity. The second patient was a man, aged 57, who was in a semi-unconscious condition when admitted to hospital. He had suffered from persistent headaches and vomiting, and there was paresis of both arms and legs. His blood pressure was 155 systolic and 95 diastolic, the pulse rate 70, and the temperature 98°. He never regained consciousness, and died in a fortnight. There was no optic neuritis.

Dr. J. T. WIGHAM described the specimens and said that in the first case haemorrhage had occurred into the mid-brain and that the blood had passed from there into both ventricles. He agreed that the condition was identical with that described by Sir James Purves-Stewart as found in cases of decerebrate rigidity. In the second case there was thrombosis of the longitudinal sinus, and the brain was adherent to the dura in the right temporal region. The right ventricle was obliterated and the left dilated. A large tumour was present in the right temporal region and was found microscopically to be a malignant glioma.

Fibrosarcoma of the Thigh.

Dr. R. A. STONEY described the case of a woman, aged 46, who had noticed a lump in her thigh sixteen years previously. It had grown very slowly until two years ago, when it rapidly increased in size. When examined the tumour was the size of half a coco-nut, was freely movable except in one part, and was situated in the superficial fascia. Dr. Stoney had removed the tumour with the overlying skin and fatty tissue, and at the operation he had found that the tumour readily peeled off the deeper structures and was apparently encapsuled.

Dr. WIGHAM demonstrated the specimen, and said that microscopic sections showed it to be a fibrosarcoma. He had no doubt as to its malignancy.

Dr. R. J. ROWLETTE referred to tumours which existed in a benign form for several years and then acquired malignant characteristics. He mentioned a case of a fibroid tumour of the uterus, which had been diagnosed thirty-five years previously; it then suddenly became malignant and caused death by intestinal obstruction. He also reported a case in which uterine polypi had occurred in successive years. These had been removed by operation, and then a sarcomatous polypus had occurred which caused the death of the patient.

Tracheal Diphtheria.

Dr. W. G. HARVEY read notes on a case which was admitted to the Adelaide Hospital as one of pneumonia. The patient was a girl, aged 18, who was six months pregnant. On admission she had difficulty in breathing and was cyanosed; the temperature was 101°, the pulse 120, and the respirations 30. The breathlessness was more suggestive of obstruction, and on examination no dullness or pneumonic breathing was found. The fauces were practically normal. Dr. Furlong examined the larynx and reported that no membrane was present, there being only some congestion. Later the patient coughed up a thick piece of membrane of the typical wash-leather appearance. This was examined by direct smear and by culture for diphtheria bacilli, with negative results. The patient was given antidiphtherial serum, but later miscarried, and about an hour afterwards died, apparently owing to respiratory obstruction and toxaemia.

Dr. J. LAIT, who had made a *post-mortem* examination, said that the fauces and larynx were comparatively free from any lesion. But the trachea, extending down to the bifurcation, the bronchi, and their smaller branches, were covered by a typical diphtherial membrane, which had completely occluded the lumina of the tubes of the smaller bronchial branches. A swab taken from the membrane at the necropsy had yielded streptococci only, but diphtheria bacilli were easily demonstrated in microscopical sections. The lungs showed a bronchial pneumonia, with areas of collapse and emphysema. An interesting point was that the membrane in the trachea was quite loose, in contrast with that of pharyngeal diphtheria. He had no doubt but that the condition was tracheal diphtheria.

Staphylococcal Septicaemia.

Dr. A. R. PARSONS read notes on a case of staphylococcal septicaemia. A man was admitted to hospital as a possible case of pneumonia. He had dyspnoea and a pain in his side; his pulse rate was 110 and his temperature 102°. The urine contained some albumin, but chlorides were almost completely absent. There were no physical signs of pneumonia. The patient had had a boil on his neck for a week before admission. Two days after admission to hospital he died.

Dr. J. LAIT said that at the necropsy there were no signs of pneumonia. A splenic puncture was made and the fluid was incubated with sterile broth. A swab from the cut surface of the spleen was also obtained and spread on a blood-agar plate. In both instances a pure culture of *Staphylococcus aureus* was obtained. No large abscesses were found in any of the organs. After numerous sections a small abscess about the size of a pin-head was found in the right lung, and another in the lower pole of the left kidney. By Gram's stain numerous characteristic clusters of staphylococci were demonstrated in microscopical sections of the lungs, and to a less extent in the kidneys and spleen.

SURGERY OF THE SPLEEN.

AT a meeting of the Liverpool Medical Institution on January 13th Professor D. P. D. WILKIE read a paper on the place of surgery in the treatment of diseases associated with enlargement of the spleen.

Professor Wilkie said that until recently the interest of surgeons in the spleen had centred mainly in the operative treatment of traumatic rupture of the organ and the rare cases of torsion of a wandering spleen. Increasing knowledge of the functions of the spleen, and thus of the part which it possibly played in diseases in which it was manifestly enlarged, had encouraged surgeons to attempt its removal in cases of splenomegaly. The effect of splenectomy on the course of diseases associated with splenomegaly was studied in many series of cases with great care and intensive observation. Sufficient data had now accumulated to permit the review of the subject with a measure of confidence, while recognizing that finality was still distant. This was essentially a borderland subject, and co-operation between the physician and the surgeon must be constant and intimate to ensure the maximum benefit to patients, and to further progress in medical science. Surgical intervention was practically never necessary in cases of septic infarct of the spleen; the special interest of these cases lay in the likelihood of the condition being mistaken for a perforation demanding immediate operation. In cases of splenic tuberculosis the question of splenectomy should be thoroughly discussed, and it was found that in certain cases removal of the organ had led to a favourable termination of a long febrile illness. With regard to syphilis of the spleen, Mayo had first drawn attention to the fact that the spleen might be the fastness in which the spirochaete might lodge and defy all specific drug treatment. He had shown that removal of the organ would permit of rapid cure by medicinal means. Malaria, cysts, and primary tumours of the spleen were then dealt with, and the splenomegalies were discussed. In splenic anaemia or Banti's disease the operation upon this condition presented two main difficulties. In some cases there were extensive and dense perisplenic adhesions which might hamper removal, and in freeing the spleen considerable haemorrhage and shock might result. The second difficulty lay with the splenic vein, which was friable from endophlebitis and might tear when ligatured. Special care would obviate this complication. When an operation was performed in the late stage of the disease in the presence of hepatic cirrhosis and ascites, the combination of omentopexy with splenectomy as advised by Tansini appeared rational and had been employed with success in a number of cases. Egyptian splenomegaly and Gaucher's disease were then described. In blood diseases with splenomegaly pride of place was given to haemolytic jaundice, because of all the blood dyscrasias associated with enlargement of the spleen it was foremost in the list of successful splenectomies. The relief following operation in this condition was so dramatic as to be almost unbelievable until actually witnessed. Splenectomy was the only treatment for haemolytic jaundice, in which it presented no special difficulties; by extirpating the organ responsible for breaking up and destroying the fragile red cells, it was followed immediately by disappearance of all the signs and symptoms of the disease. Professor Wilkie then discussed purpura haemorrhagica, pernicious anaemia, leukaemia, von Jaksch's disease, polycythaemia, and cirrhosis of the liver. In conclusion it was stated that splenectomy had now an established place in the treatment of certain diseases characterized by splenomegaly—namely, in acquired haemolytic jaundice, in chronic purpura, in splenic anaemia, and in Gaucher's disease. It might be used with benefit in a few selected cases in certain diseases, such as splenomedullary leukaemia, pernicious anaemia, von Jaksch's disease, and tuberculous and syphilitic splenomegaly. The operation was not indicated in a third group of diseases in which enlargement of the spleen was found—namely, malaria, polycythaemia vera, and acute leukaemias.

Dr. S. W. PATTERSON, dealing with the medical aspects of the subject, said that with x rays the spleen could be shown directly and also indirectly by the deformity of the greater curvature of the stomach or splenic flexure of the colon when these organs were distended with opaque material. He agreed that in cases of acholuric jaundice splenectomy was the treatment of choice, and illustrated the familial type of this disease by describing a family of twenty-nine members. Seventeen members of this family were affected; eight of them had had the spleen removed, with immediate relief of the jaundice and lessening of the anaemia, but the fragility of the red blood corpuscles was apparently unaltered; in one case it was present eighteen

years after splenectomy. In pernicious anaemia the results were not good. In the condition of purpura depending on a dyscrasia of the blood platelets splenectomy gave satisfactory results. Dr. Patterson emphasized the good results of x-ray treatment of spleen and long bones in leukaemia, and concluded with the remark that although the spleen was far from being a superfluous organ, the normal spleen could be excised without seriously injuring the health; a spleen acting abnormally was a dangerous organ and ought to be removed.

EXPERIMENTAL CANCER RESEARCH.

AT a meeting of the Cardiff Medical Society on January 18th, Dr. ALFRED HOWELL in the chair, a paper on "The story of experimental cancer research" was read by Professor E. H. KETTLE.

Professor Kettle said that the systematic experimental investigation of cancer began with the publication of Jensen's papers in 1902-3, in which was announced the successful propagation of a mammary carcinoma of the mouse through many generations. Jensen's tumour was exhaustively studied in this country and on the Continent, and very soon other spontaneous tumours in mice and rats were recognized and made available for further study. Much information about the general biology of malignant tumours and the special features of individual examples was gradually accumulated; but it had become recognized that the study of propagated tumours was only of limited value. In any series of inoculations tumours failed to grow in a certain proportion of the animals. Further, some tumours, after a period of progressive growth, retrogressed and finally became completely absorbed, when the mice in which this had occurred became refractory to further inoculations with the same brand of tumour. These observations fitted in well with the current trend of pathological thought, and the investigation of natural and acquired immunity to the inoculated tumour was entered upon with high hopes. Unfortunately, though mice could be rendered immune to inoculation with tumour tissue, no means had been discovered to control the progress of spontaneous tumours. About this time, when it seemed that experimental cancer research had reached a dead end, it received a welcome stimulus from the work of certain Japanese investigators, who demonstrated the possibility of producing cancer of the skin in animals by exposing them to irritants, especially tar. This line of research had been fruitful in results, and had still great possibilities. It had been shown, for example, that as a general rule cancer of the skin could only be produced by the repeated action of the irritant and developed only after a considerable period of time—a period corresponding to some twenty or thirty years in the life of man. At the same time, it was not necessary to apply the irritant throughout the whole of this period; a couple of months' application of tar might be followed four months or more afterwards by the development of cancer. Of even greater significance in their bearing on human pathology were certain observations which tended to prove that a local cancer was associated with a definite constitutional change. After referring to the study of the cancer cell in *in vitro* cultures, Professor Kettle briefly dealt with the recent work of Gye and Barnard. He pointed out that all the work of the past showed that, with one exception, malignant growth could only be propagated by the inoculation of the actual living cell. This exception was the sarcoma of fowls described and studied by Peyton Rous, which could be propagated by a cell-free extract. Gye had demonstrated that this cell-free extract contained two substances, neither of which was capable of producing a tumour when used alone, though in combination they could do so. Gye claimed that one of these factors was a non-specific living virus, and on the optical side he was supported by Barnard's work. All this research was still very recent, but it had received already a considerable degree of confirmation, and was obviously of the first importance. Indeed, its bearing on the general problem of infection might eventually outshadow its application to the more limited pathology of tumours.

Reviews.

PROSTATIC ENLARGEMENT.

MR. KENNETH WALKER has made a welcome contribution to surgical literature in his book entitled *The Enlarged Prostate*.[1] The work deals with simple enlargement of the gland, though in the discussion of the differential diagnosis other affections of the prostate are brought in.

The opening chapter deals with the anatomy, physiology, and development of the gland, and with the nervous mechanism of micturition and ejaculation. The author reminds his readers that we are ignorant of the pathology of prostatic enlargement, and that age is the only certain factor in its etiology. The gross naked-eye changes in the urethra, bladder, ureters, and kidneys are described in detail, while the symptoms, diagnosis, and differential diagnosis are fully discussed. The chapter on cystoscopy is good, but we would have preferred that a cystoscope of British manufacture should be taken as an illustration, for, in our opinion, they are quite as good as those of foreign make. The same remark applies to his rather scathing view of gum-elastic catheters of British make.

A really excellent diagram illustrates the common complications of prostatic enlargement in the genito-urinary tract, and this is followed by a description, in full detail, of the treatment of each complication. A mental appreciation of this diagram would be most helpful to any student or practitioner. The methods of carrying out the different laboratory renal function tests are given; the author does not trust to any single test, but requires to know the results of different tests for each case. While appreciating the value of these tests, he emphasizes the importance of correlating the information they give with that obtained from the clinical examination of the patient, for on the results of the latter should depend the final decision whether to operate or not. A chapter is devoted to the important subject of anaesthesia, including local, sacral, spinal, and general. We agree with the conclusion that bronchitis is as common with spinal as with general anaesthesia.

The question of prostatectomy by the perineal route is fully gone into; Mr. Kenneth Walker rates the difficulties and complications of this operation high, and in considering the choice of operations discusses the pros and cons. He holds that the perineal operation is one for experts only, and that prostatectomy by the suprapubic route is much safer in ordinary hands. The operations of cystostomy and suprapubic prostatectomy are described in full detail in a way most helpful both to the student and to the young surgeon. The different methods of controlling bleeding from the prostatic cavity are related, and he expresses a preference for Pilcher's haemostatic bag. Treatment after operation is detailed, and particularly his methods of combating shock, pain, secondary haemorrhage, etc. The different methods of attaining bladder drainage and of avoiding pelvic cellulitis are discussed, and the frequency of post-operative epididymitis is commented on. He goes into the causes of post-operative obstruction to micturition, and makes recommendations on how to avoid this complication and how to treat it if it arises. The chapter on prostatism without enlargement is probably the most interesting in the book—perhaps because the successful treatment of this condition is so difficult. In this type of case he advocates a perurethral operation, which, he considers, gives the best results. He recommends diathermy for removal of the obstruction, and a full description, with helpful illustrations, is given of his method of performing this operation; a table of results in thirty consecutive cases is given; two of these patients died from acute renal sepsis which was present prior to the diathermy; he thinks these deaths might have been avoided had a preliminary cystostomy been done.

The book is an excellent review of the subject from every aspect; it is written in a systematic way, and is, therefore, easily read and easily grasped. For those who wish to go deeper into particular portions, an excellent table of refer-

[1] *The Enlarged Prostate.* By Kenneth M. Walker, F.R.C.S., M.A., M.B., B.C. Oxford Medical Publications. London: Milford, Oxford University Press. 1926. (Demy 8vo, pp. xi + 193; 59 figures, 1 plate. 12s. 6d. net.)

ences is provided at the end of each chapter. The book is of a handy size, the text is good, while the illustrations are ample, helpful, well chosen, and well produced. It is a work that can be safely recommended, both to the young surgeon and to general practitioners whose responsibility it may be to advise a patient with an enlarged prostate.

PARSONS'S "DISEASES OF THE EYE."

IT cannot be said to redound to the credit of English ophthalmology that it is without a standard textbook, and that it has to rely in this respect upon an American translation—or, more correctly, adaptation—of an Austrian work. We refer to the textbook of Fuchs and Duane. It is the only one of the important subdivisions of medicine and surgery that is in so sorry a case. To compensate for this, however, it is possessed of several manuals and handbooks of more than average value. Of these undoubtedly the best esteemed and most complete is *Diseases of the Eye*,[2] by Sir JOHN H. PARSONS, the fifth edition of which is now before us. Succeeding editions of this manual have been noticed in these columns from time to time, and each successive edition has been commended for its many excellencies. The book is already so well known to the majority of our readers that a review of its general plan is unnecessary; the new edition differs from its predecessors only in being more complete and up to date, and in containing adequate accounts of those advances in diagnosis and treatment which have been introduced in recent years, and the large number of minutiæ of detail that the slit-lamp has revealed are described. The already profuse supply of illustrations has been increased, and many of the old ones have been redrawn and improved.

The distinctive virtue of this manual is that it is founded on a rich personal experience and informed by a sane judgement, which have put the author in a position to express definite and authoritative opinions. So many books of this kind—erudite though they may be—are mere compilations of the experience of others. Theory after theory is advanced and left in the air, or a bewildering array of methods of treatment are offered as possible alternatives, the reader being left to make his choice. But the reader more often than not is a student or practitioner who is seeking advice and guidance in his difficulties; with no means of knowing how to sift the profusion of alternatives offered him, and with no experience to guide him in his choice, he is little better off. Time and again throughout the pages of this work we read that "this and that have been suggested . . . but I think," "this, that, and this other have been advocated . . . but I prefer." And the opinion is always a well considered one, and the preference based upon an experience which is unrivalled.

If there is one thing which may seem to detract somewhat from its value, though only in a limited sense, it is that for the student of general medicine, with his many interests, it may appear at first sight to be somewhat too large. It is impossible to cater for all classes simultaneously, and as a manual for the student of ophthalmology and as a reference book for the practising ophthalmologist or medical man it certainly is not too large. They will find it a masterpiece of much in little, and of compression, without an unnecessary word, of a mine of information and a wealth of detail into the minimum of space; at the same time it is easy to read, and preserves throughout perfect clarity of exposition. With all its additions the fifth edition is only seventeen pages larger than its predecessor. If it is to preserve its distinctive character as a manual the same principle should be adhered to in successive editions. To enlarge it would be to fall between two stools. Even as it is, a manual in size, its completeness almost raises it to the dignity of a textbook. At the same time the student of general medicine will find so much of interest to him in neurology and medicine, and so much that is essential to him in the medical aspects of ophthalmology, that he will admit it a sound investment, and the hours spent over it well spent indeed.

[2] *Diseases of the Eye.* By Sir John Herbert Parsons, C.B.E., D.Sc., F.R.C.S., F.R.S. Fifth edition. London: J. and A. Churchill. 1926. (Extra post 8vo, pp. viii + 676; 343 figures, 19 plates. 18s. *net.*)

INDUSTRIAL HYGIENE.

THE Germans and Austrians appear to be paying for the war in small part by inflicting on the libraries of foreign countries the purchase of voluminous and expensive scientific publications. In the matter of scientific journals the German publishers seem to think that they can charge according to the bulk of their volumes and the length of the articles—a most pernicious arrangement. It is becoming a question whether it is worth while to continue to purchase periodical publications the issues of which have been so greatly expanded, often by mere padding. The libraries naturally do not want to break the continuity of sets of famous old journals, and German publishers appear to be playing upon this fact. *Körper und Arbeit*[3] is a voluminous publication dealing with the physiology of work compiled by several authors, such as René du Bois-Reymond, Arnold Durig, and Robert Herbst. The first part consists largely of anatomical and physiological details which are to be found in the textbook of anatomy and physiology, and might well have been omitted.

The chapters on the energy output and metabolism, and on rationalization of work by Dr. Atzler, those on the theory and practice of fatigue by Professor Durig, on the food of the worker by Dr. Lehmann, on clothing and on sport and work by Dr. Herbst, are to the point. Those interested in the physiology and efficiency of muscular work will find a great deal of information laboriously gathered together, and may use this weighty and rather dull volume with advantage for reference. The British Industrial Fatigue Research Board deals with the problems here discussed, and one member of the Board, Professor A. V. Hill, has contributed more than anyone in recent years to the physiology of muscular work; his researches are adequately summarized, but those on ventilation of workshops by Leonard Hill, Vernon, and others, a subject of the greatest importance to industry, are but briefly referred to.

COMPARATIVE PHYSIOLOGY.

IN contributing a volume on *Comparative Physiology*[4] to the Textbooks of Animal Biology, Professor L. T. HOGBEN has provided both stimulus and means wherewith the zoologist may enrich his knowledge by a vivid glimpse of the experimental methods and results most intimately related to his interests; at the same time it will enable the physiologist to pursue the fascinating inquiries of the last decade in which his methods are applied to problems and material not primarily concerned with an analysis of mechanisms known or suspected in man.

Two hundred and nineteen pages suffice to present an immense variety of phenomena, many of which show unexpected relations between the functions by which lower organisms develop and maintain life and those familiar in the study of mammalia. The diversity of nature is no longer accepted with the resignation of Winterstein, in his comprehensive treatise (1912), as due to "Artverschiedenheiten," but is gradually being woven into a pattern, the significance of which can, at occasional points, be detected. The subjects chosen for discussion, as indicative of such a change, are described in sufficient detail to induce interest and appreciation in readers with little previous specialized knowledge.

A high standard of accuracy is reached, and where a particular subject is described at all, few of its recent developments are omitted. The absence of reference to Kato's work on isolated nerves may perhaps be quoted as an exception. The title of the book would suggest that the comparative method had received considerable attention, but it has not yet been applied to any great extent to the data of general physiology. It may be hoped, however, that the re-orientation of material which is now in progress, and is here described by Dr. Hogben, may make the comparative, as contrasted with the experimental, method a more prominent feature of a future edition.

[3] *Körper und Arbeit.* Herausgegeben von Prof. Dr. Edgar Atzler. Leipzig: G. Thieme. 1927. (6½ × 9½, pp. xii + 770; 102 figures. M.42.50.)

[4] *Comparative Physiology.* By Lancelot T. Hogben, M.A.Cantab., D.Sc.Lond. Textbooks of Animal Biology. London: Sidgwick and Jackson, Ltd. 1926. (Demy 8vo, pp. xiv + 219; 44 figures. 7s. 6d. net.)

ANNALS OF MEDICAL HISTORY.

THE last or winter number of the eighth volume of *Annals of Medical History*[5] has on its cover a portrait of John Caius, who is referred to in Sir Humphry Rolleston's article on some worthies of the Cambridge Medical School. The frontispiece represents Francesco Redi (1626-1697), philosopher, physician, and poet, to whose memory Dr. Rufus Cole devotes an interesting biography. Dr. W. S. Miller gives the results of some years' inquiry into the life and doings of Abraham Chovet (1704-1790) of Philadelphia, a successful teacher of anatomy, who was described by S. Weir Mitchell's father as "a very bad man"; he left behind him a large number of anatomical models. Dr. E. B. Krumbhaar gives a description of the thirty-five medical medals and tokens he is presenting to the College of Physicians of Philadelphia, and comments on the comparative scarcity of English papers on medical numismatics. "The Worship of Asklepios, with special reference to Tholos and the Theater," is the title of a finely illustrated article by Dr. Ira S. Wile. Dr. Casey A. Wood writes on the medicine of ancient and mediaeval Ceylon under the heading "Ayurvedic Medicine." Dr. Herbert Fox of Philadelphia, in a particularly interesting article, shows that three of Thomas Hodgkin's original cases of the disease that goes by his name were (as proved by microscopical examination of specimens in the Guy's Hospital Museum, which the authorities allowed him to make) histologically identical with that now recognized. He, however, follows other American writers in giving the credit for establishing the histological characters of Hodgkin's disease to Miss Dorothy Reed (1902), and does not mention Sir F. W. Andrewes's description in the same year. Further, as four years before Hodgkin's paper appeared Craigie recognized that there was a disease midway between tuberculosis and cancer, Dr. Fox suggests that it might with some propriety be called after him. Dr. Roy L. Moodie provides two more studies on palaeopathology dealing with tumours of the head among pre-Columbian Peruvians, and with Pleistocene examples of traumatic osteomyelitis.

NOTES ON BOOKS.

The Personal Equation,[6] by LOUIS BERMAN, is much on the same lines as his previous book *The Glands Regulating Personality*, for both are addressed to the lay reader. It is written in rather superior journalese; a sentence such as "Every person begins as a minute droplet of that peculiar, mysterious, wonderful jelly known as a protoplasm" is hardly meant for professional consumption. The argument throughout is the influence of the endocrine glands on personality, and, as in the previous volume, well known men are taken to afford illustrations of the predominance of certain ductless glands. Thus two portraits at different ages of President Woodrow Wilson are introduced to show the facial characteristics of the pituitary-centred type, while President Harding figures as presenting the salient characteristics of an adrenal-centred individual, and Raphael as a thymus-centred person. The nine chapters include several with catchy titles, such as "Are we gland-controlled marionettes?" The author argues that the influence of the endocrine glands is more important than that of heredity.

In *Types of Mind and Body*[7] Dr. E. MILLER covers some of the ground, though in rather a different way, as Dr. Louis Berman does. In fact, he does not admit that writings such as Berman's have yet established a science of character based on endocrinology. The style of his otherwise well written book shows a preference for long words and a method of expression more popular than that ordinarily found in a medical monograph; the substance, however, is hardly adapted, and presumably is not intended, for the lay reader, who might be surprised to light on a sentence such as "the centre of gravity of our norm of human behaviour lies nearer to the cyclothymic reaction than it does to the schizothymic reaction," even though the cyclothymes and the schizothymes have been defined on an earlier page. This "Psyche Miniature," which is intended to show how physical conformation can be correlated with mental reaction, contains four chapters, dealing with morphology, the physiological background, the psychological aspect, and cross-currents. In the second of these the influence of the endocrine glands on the economy of the organism and on temperament and character is discussed, and the author appears to accept Eppinger and Hess's conception of vagotonia and sympatheticotonia. Later, when dealing with the psychological aspects, Michael Angelo and Leonardo da Vinci are mentioned as examples of characters with definite schizothymic marks and asthenic physiques, and Paul Verlaine's portrait is given to show his pyknic face and stout physique, almost Mongoloid in quality; Charles Baudelaire, of whom a caricature and a rather striking picture are also introduced, had a dominantly asthenic physique. The previous description of the various types is supplemented in the chapter on "Cross-currents" by consideration of the variations in the types of mind and body, and in this connexion the mental characters of John Bunyan, Lord Byron, and Milton are analysed.

The volume on *General Medicine* of the "Practical Medicine Series (1926)"[8] is, like its predecessors (see JOURNAL, July 12th, 1924, p. 59; February 7th, 1925, p. 270), divided into four parts, and is under the same editorship as in previous years. Recent work on infectious diseases and endocrinology is reviewed by Dr. George H. Weaver, assisted by Dr. T. Crooks. Diseases of the chest, excluding the heart but including tuberculosis, are discussed by Dr. Lawrason Brown, who pays special attention to treatment by sanocrysin and artificial pneumothorax. Dr. Robert R. Preble deals with the blood and the blood-making organs and diseases of the blood vessels and the heart, paying special attention to subacute endocarditis, blood pressure, and nephritis. Dr. Ralph C. Brown reviews the recent literature of diseases of the digestive system and metabolism, as well as the diseases of the liver and gall bladder.

In *Aids to Memory for First Aid Students and Nurses*[9] Dr. VERNON NEWTON has collected a number of mnemonics for the benefit of students of first aid and home nursing. Although the book makes no claim to be a textbook, or even a book of reference, it contains a considerable amount of information in compressed form.

In *The Gang Age*,[10] a small book by Dr. P. H. FURFEY, is given a brief psychological study of a young boy between the age of 8 or 10 years and puberty. It is a period of life when the influence of home, and especially of parents, becomes weaker, while school and the wider world offer new interests and activities both to the mind and the body. The interest of the book is social and educational, and although its outlines are broadly drawn it will be read with profit by parents and teachers. A valuable feature is a short bibliography at the end of each chapter, which will be welcomed by those who desire to pursue the subject further. The book is a useful and interesting contribution to the psychology of later childhood.

PREPARATIONS AND APPLIANCES.

Neutralon and Belladonna Neutralon.

NEUTRALON is a synthetic aluminium silicate with the formula $Al_2Si_2O_{15}$. Weak solutions of hydrochloric acid slowly split it up, forming aluminium chloride and insoluble silicic acid. Neutralon therefore appears to be a valuable new remedy for treatment of hyperacidity of th[illegible] drug neutralizes excessive hydrochloric acid carbon dioxide, and the insoluble precipitat[illegible] a protective coating for the mucosa of the [illegible]ts as a gastric sedative. Fairly extensive clinical tests have been made with the drug in Germany and the reports are satisfactory. "Belladonna neutralon" has the same formula as neutralon, but contains in addition 0.6 per cent. of extract of belladonna. This compound has the same action as neutralon, but in addition the belladonna, by paralysing the vagal nerve endings, exerts an action which may be valuable where there is excessive vagal irritability. Since belladonna is toxic in excess, belladonna neutralon must be given with a certain degree of caution, and should not be repeated too frequently. These preparations are supplied by Messrs. Schering, 3, Lloyd's Avenue, London, E.C.3.

JANET'S TEACHINGS.

THE French school of psychiatry, during the century or more for which it has existed, has always been remarkable for the independence of its judgements and the originality of its ideas. Professor Pierre Janet, who is to-day the most influential of its representatives, is amply endowed with both of these qualities, and has proved himself an inspiring teacher. In his clinical work he follows the inductive method, not hesitating to follow where the facts lead, while when he comes to put his ideas into lectures or essays he leans to the deductive, setting out a proposition or theory, and substantiating it by reports of cases, related with all the skill of an accomplished story-teller. His writings are many, and for the most part scattered. It is therefore convenient to have various courses of lectures he has given in Boston and elsewhere brought together in an English translation,[1] so excellently made that it may be read with pleasure, and almost as a pastime.

It is perhaps true, as Janet affirms, that many medical practitioners are inclined to entertain a very poor opinion of psychotherapy, and to regard it as almost useless. They maintain that some patients will get well spontaneously, and that others will inevitably drift into chronicity; they believe that medical skill makes but little difference in such cases. Thus many medical men succumb to the "monstrous prejudice," against which Magnan indignantly used to protest, "that we can do nothing for our cases." Did this view correspond to facts, the doctor, when confronted with the anxious, depressed, deluded, or obsessed patient, would have little to do but assume an attitude of resignation and inactivity. Fortunately, however, such an opinion is untenable; the "war-shocked" soldier was cured by removal from the situation which provoked his neurosis and by the application of psychotherapeutic measures; similarly, it is often possible to dispel the symptoms of the more complex neuroses or psychoses of civil life by the removal of situations which have a traumatic significance and by the use of methods designed to straighten out internal disharmonies. To deny, indeed, the value of psychotherapy would be to deny the value of environment, education, and moral guidance in the development of personality, since psychotherapy consists in a large measure in the elaboration and application of methods which are utilized in daily life to influence the minds of normal persons. The ways and means of psychological healing are many and varied, and each is described and submitted to a critical discussion. Consideration is first given to miraculous and philosophical healing. Christian Science is included in the latter category, and akin to this is Dubois's system of "medical moralization," the aim of which was to encourage the patient to ignore his neurotic symptoms, and to induce him to cultivate the higher moral qualities. Janet devotes much attention to treatment by hypnotism and suggestion—methods in which a cure is attempted by making use of the patient's automatism. Treatment by rest, isolation, and "mental liquidation" is next discussed. Under the last term Janet includes those methods in which recovery depends upon unburdening the mind of traumatic memories. The discussion of this subject is largely concerned with a criticism of psycho-analytic theories. Janet expresses the view that, despite much exaggeration and distortion, psycho-analysis has unquestionably done a great deal to promote interest in psychiatric researches and has initiated a notable movement in ideas. He does not, however, accept Freud's sexual theory of the neuroses. Briefly, he takes the view that the sexual inadequacy which the neurotic exhibits is a symptom, and not a cause, of his neurosis. He quotes with approval Lyman Wells's generalization to the effect that in our civilization the sexual life has become a difficult matter, so that it is, as it were, a "touch-stone of our powers of mental adaptation." Thus disorders of the sexual functions are amongst the commonest and most inevitable manifestations in the subjects of a neurosis.

The methods which aim not only at using and saving what a patient already possesses, but also at enabling him to acquire further tendencies or to recuperate those which he has lost, call for careful study. They are far less precise than those to which reference has been made above, and the psychological notions upon which they depend are far less definite. Janet deals with them under the headings of education, excitation, and guidance, and gives particular attention to psycho-physiological methods of treatment.

In his discussion of treatment by isolation Janet reveals perhaps most fully his great clinical insight and his understanding of the neurotic character. Here he discusses the social reaction of his cases, showing how their capricious and exacting behaviour is liable so to deplete the energies of their associates as to produce a kind of collective neurosis. They demand everything and give nothing. The effect of such individuals upon others has a bearing upon the problem of heredity. A child of psychopathic parents grows up in a family atmosphere which will tend to exert an unfavourable influence upon its mental development; it will be submitted to a species of persistent and insidious psychic trauma which converts an otherwise healthy child into a neurotic. It would seem highly probable, as Janet brings evidence to show, that many mental invalids, whose morbid reactions are attributed to heredity, are in reality the product of an unhealthy domestic atmosphere.

Many of the patients described by Janet are not recognized as the subjects of mental disorder. Not only would they themselves indignantly repudiate the suggestion that they were mentally ailing, but, in many instances, those with whom they were associated would be surprised to learn that a person whom they had regarded as merely difficult, trying, and irksome to live with was in reality suffering from a recognizable form of mental illness. It is due to the pioneer work of such clinicians as Janet that these hitherto neglected and often unrecognized forms of mental illness, the description of which was left to the novelist, are now increasingly engaging the attention of the medical profession. The psychopathic personality and the psychoneurotic are not only themselves ineffective and unhappy, but they so tend to exhaust the energies of others as to create in them also ineffectiveness and unhappiness. Such persons may do

[1] *Psychological Healing: A Historical and Clinical Study.* By Pierre Janet. Translated from the French by Eden and Cedar Paul. In two volumes. London: George Allen and Unwin, Ltd.; New York: The Macmillan Company. 1925. (Demy 8vo; the two volumes, pp. 1265, 42s. net.)

as much harm to their associates as cases of physical infection, though the effects of the latter are more obvious. The family practitioner can probably do most to diminish the incidence of these so-called "minor psychoses" in the community. Many of them are largely the outcome of an unhealthy domestic situation, and the family doctor who realizes that psychopathic parents may unwittingly be responsible for the creation of neuroses in their children may do a great deal to prevent their occurrence by tactfully giving the educational recommendations which may seem to be called for in the particular case. Unfortunately the situation is rendered difficult by the psychic blindness which most individuals exhibit in regard to their own defects of character. The time may come when the physician will be called upon to give advice in cases of domestic inharmony (usually due to mental abnormality in one or more members of the family group) as readily and promptly as in those of physical illness. Before this most desirable state of affairs can come about, however, several conditions must be fulfilled. In the first place, there must be wider diffusion of a knowledge of the principles of mental hygiene, and the significance of mental twists in children must be fully appreciated by those responsible for their care; in the second, the study of personality disorders must take a larger place in the medical curriculum; and in the third, the psychopathologist must endeavour to communicate his knowledge in language as simple as possible. As regards the last condition, however, it can certainly be said that Professor Janet has not erred in presenting his subject in a manner which the busy practitioner will find it difficult to understand.

POST-GRADUATE POSSIBILITIES.

THE fact that, in spite of many disappointments, delays, and failures, it is still easy to get influential support for a proposal to improve the conditions of post-graduate medical education in London is proof of the vitality of the idea. Everyone who approaches the problem for the first time, even if he does not take the trouble to make himself acquainted with the history of what has been done since the Special Clinical Meeting of the British Medical Association in 1919, at once perceives that there are two sides to the question—the educational and the social. The full title of the chief body now active in London is the Fellowship of Medicine and Post-Graduate Medical Association. It was produced by the amalgamation of two bodies—the one founded by the late Sir William Osler and Dr. Hurst, for education; the other by Sir StClair Thomson and the late Sir John MacAlister, for social purposes. The latter purpose seems rather to have passed out of sight, but the need for an organization of the kind has not diminished. The Post-Graduate Hostel was established in London in order to meet both demands. It was opened at the end of last July, as reported in our columns at the time, and we have since regularly given particulars with regard to the meetings it has held. Its aim was to bring together socially post-graduate visitors to London, whether resident in this country or overseas. It sought to do this by social meetings and by discussions, to be held on two nights a week. The desirability of having in London such an institution met with very general approval, but, unfortunately, its financial basis was not sound; it has consequently been found necessary to wind up its affairs. Their experience has convinced its promoters that any experiment of the kind ought to have behind it either a sufficient capital sum to provide a really satisfactory hostel, or a moderate but certain annual income if a smaller experiment were to be tried.

The decision to close the Hostel was reached at a meeting on January 31st, and the resolution to bring the experiment to an end was accompanied by a cordial vote of thanks to Mr. A. P. Bertwistle, M.B., F.R.C.S.Ed., the director of the Hostel, for the trouble he had taken in connexion with its initiation and the success with which he had arranged an interesting series of discussions. Most of those present at the meeting at which this resolution was adopted afterwards dined together and heard an address from Sir Arthur Robinson, First Secretary of the Ministry of Health, on "Our duty to Colonial visitors." He expressed a confident anticipation that the time would come when London would provide a post-graduate school worthy of it, and added that an essential part of that school must be a hostel to help in attending to the social side. The Ministry of Health, he said, was impressed with the importance and urgency of the problem generally, but especially in regard to the insurance medical service. He did not omit to mention the report of the Post-Graduate Medical Committee appointed six years ago by Dr. Addison, then Minister of Health, but it may be opportune for us to recall that this departmental committee, of which the Earl of Athlone was chairman, recommended that a post-graduate medical school, with a hospital centrally situated, should be formed in London, and that it should be a school of the University of London, receiving substantial financial assistance from the Treasury through the University Grants Committee. It also recommended the establishment by the University of London of an Institute of State Medicine, in which instruction would be given in public health, forensic medicine, industrial medicine, and in medical ethics and economics. This final recommendation was almost immediately realized through the gift of the Rockefeller Foundation of two million dollars for building and equipment, on condition that the British Government undertook to provide for maintenance and running expenses. Sir Alfred Mond, who had become Minister of Health in the interval, promised that Parliament would find the necessary subvention, estimated at £25,000 a year. A royal charter was granted, and it was arranged that the new institution should take over the London School of Tropical Medicine. A second donation of £4,000 a year was subsequently promised by the Rockefeller Trustees to maintain a director and administrative staff, and Dr. Andrew Balfour was appointed director in October, 1923. Plans were got out under his supervision, and the foundation stone of the new building now rising in Keppel Street, near Gower Street, was laid by the Minister of Health, Mr. Neville Chamberlain, last July. The other recommendation of the Athlone Committee—that for the establishment of a general post-graduate school in London—has hung fire, but hope rose again when, in August, 1925, Mr. Chamberlain appointed a committee "to draw up a practical scheme of post-graduate medical education centred in London," and himself became its chairman. This committee, Sir Arthur Robinson told his audience, has been engaged in a most thorough and careful study of the problem in all its aspects, and he expressed the expectation that the labours of the committee "will not fail of fruition in the discovery of a solution of this most difficult and important problem." While he refrained from any

forecast of the recommendations of this committee, he went so far as to say that the Ministry of Health recognized that any scheme, to be successful, must include a hospital, educational facilities, and an organization, and a place where men from this country and from overseas could meet as friends, exchange ideas, and be put in the way of knowing exactly where they could obtain what they wanted, whether specific experience in one subject or more general knowledge. We hope that the report of this committee may not be too long delayed, and venture to express the opinion that if anything really worthy of this country is to be done it must be with the concurrence of the University of London, which would probably ensure that "substantial financial assistance from the Treasury through the University Grants Committee" of which the Athlone Committee spoke.

The thanks of the meeting were conveyed to Sir Arthur Robinson by Sir Thomas Horder, Bt., honorary treasurer of the Hostel, who was in the chair. The address, he said, had been really helpful and cheering on a somewhat depressing occasion.

MEDICAL GOVERNORS.

THE appointment of Lieut.-General Sir John Goodwin, K.C.B., to be Governor of Queensland was mentioned in our issue last week (p. 268). His record as an administrator during his term of office as Director-General, Army Medical Service (1918-1923), and his services with Mr. Balfour's mission to the United States in 1917, when he represented the medical profession of this country to the medical profession in the United States, assure his success in the new and important office for which he has been selected. It is not often that Colonial Governors have been chosen from among the ranks of those who have been trained as members of the medical profession, and it must be still more seldom, if ever, that a medical man who has served in a professional capacity till he has reached to the highest post open to him in his service has been chosen to be Governor of one of the great self-governing Colonies—if it is still permissible to describe one of the States of the Commonwealth of Australia as a colony. It is a curious coincidence, if it be altogether a coincidence, that Queensland has already had a member of the medical profession as Governor; this was Sir William MacGregor, G.C.M.G. After a long career in the Colonial Service he became Governor of Queensland in succession to Lord Chelmsford in 1909. After holding the office of colonial medical officer in Fiji, to which he was appointed in 1875, three years after his graduation at Aberdeen, he was Governer in succession of British New Guinea, Lagos in West Africa, and Newfoundland. His career was varied and adventurous, and he was a most valuable public servant. He retired in 1914, in which year he was appointed a Privy Councillor, and died in 1919. Other members of our profession have similarly given up active practice and drifted, as it were, into the diplomatic service. Of these Sir Rutherford Alcock was a distinguished example. After a term of service as house-surgeon to the Westminster Hospital, he was appointed in 1832 surgeon to the British-Portuguese forces in Portugal, and in 1836 he was transferred to the Carlist forces in Spain, becoming Deputy Inspector-General of Hospitals to that force at the age of 28. He soon, however, returned to London, and lectured on surgery at the now dead and forgotten Sydenham College. But it was in China that Alcock made his reputation. Abandoning medicine, he was appointed in 1842 consul at the newly opened treaty port of Fuchow. At Amoy with Sir Harry Parkes he did good service in "bringing home to the minds of the Chinese officials that treaties were solemn engagements and not so many promises that were to be whittled away at the will of the mandarins."[1] Some such persuasion seems to be too sorely needed in the present crisis. Alcock took a great part in the establishment of the international settlement at Shanghai, which has since developed into such a great place of business and trade, and is at present so much in the public mind. Afterwards he was sent to Japan, and took part in 1861 in the defence of the legation against the Japanese swordsmen when Laurence Oliphant was severely wounded, as described by himself in his *Episodes in a Life of Adventure, or Moss from a Rolling Stone*, published in 1887. After serving as Minister Plenipotentiary at Peking with great distinction, Alcock returned to London, where he held various honorific offices, and died full of years and honours at the age of 88. The career of another alumnus of Westminster Hospital comes down nearer to our own day, and is probably remembered by many readers. This was Sir George Scott Robertson, K.C.S.I., M.P., who entered the Indian Medical Service soon after his qualification in 1876, and served in the North-West Provinces as a civil surgeon, afterwards entering the Foreign Department of the Indian Government as agency surgeon at Gilgit. From this time his services were more diplomatic and military than medical, and the heroic defence of the agency by its garrison under his command thrilled the whole British Empire. On his return to England he sat in the House of Commons for Bradford for some years, and died in 1916. Thus he was not only one of the few medical diplomats, but also one of the few medical members of Parliament of his time. There are other members of the profession who have served their country as administrators or diplomats whom space prevents our mentioning, except Sir Auckland Geddes, who represented this country as Ambassador at Washington from 1920 to 1924. In the United States of America a parallel is furnished by General Leonard Wood, Governor of the Philippine Islands, who, at the age of 24, commenced medical practice in a Boston slum. He subsequently entered the medical service of the United States Army during the war against the Apaches, but soon became a combatant officer, receiving the highest award for gallantry in action. Subsequently he was physician to the White House, under the Presidencies of Cleveland and McKinley. He rose to the rank of brigadier-general in Cuba in the course of the war with Spain, and was Governor of Santiago; in 1910 he was appointed chief of the staff of the United States Army. He held a high command during the late war, and was wounded at the commencement of 1918 in France by the bursting of a gun. After the war he returned to administrative work and became Governor of the Philippines, where, as in Cuba, he has been largely responsible for the establishment of civil peace and good sanitary conditions.

SIR PATRICK MANSON.

MR. NEVILLE CHAMBERLAIN will unveil a memorial tablet to the late Sir Patrick Manson in the Manson ward of the Royal Albert Docks Hospital on Tuesday, March 15th, at 3.30 p.m. It is very appropriate that this tablet should be erected at this particular hospital, for it was there that Manson carried out so many of his epoch-making researches, and there that he laid the foundations of the teaching of tropical medicine; he gradually gathered about him an enthusiastic staff, and the numbers who attended the periodical classes steadily increased. It is very appropriate also that the ceremony should be performed by Mr. Neville Chamberlain, for it was his father, Mr. Joseph Chamberlain, who, by his convincing pleading, obtained from the public contributions to a fund which made it possible to

[1] *Dictionary of National Biography*, 1st Supplement, p. 29

finance the scheme in its early stage. Those whose memories go back long enough will vividly recall the speech Mr. Joseph Chamberlain made in London in 1899, pointing out first the responsibility laid on this country to undertake research into the diseases which rendered many tropical colonies almost uninhabitable for the white man, and the obligation upon it to educate the young medical men it was sending out in what was already known with regard to the prevention and treatment of these diseases. The speech was a model of lucidity, comprehensiveness, and eloquence. The response was immediate, but Mr. Chamberlain was not content to make this one effort; he was persistent in using his great influence to ensure the success of the scheme, and both he and Manson lived long enough to be sure that it was to be a permanent success. In 1920 the school was removed to the large building in Endsleigh Gardens, where it was under the same roof as a hospital for tropical diseases. The school welcomes, as Mr. Chamberlain said in 1899, officers appointed to the medical services of the colonies and protectorates, to receive, before leaving England, systematic instruction, with special facilities for clinical studies, and also doctors already in the service who, when on leave in England, are afforded opportunities of bringing their professional knowledge up to date. The plan of the school formulated by Manson was so thoroughly thought out as to ensure success, and at the time of his death in 1922 no fewer than 2,544 persons had passed through the courses, and the majority of them had taken the school's certificate of proficiency. In 1904 the importance of education in tropical medicine was recognized by the University of Cambridge by the creation of a diploma in the subject. The School of Tropical Medicine in London, and the sister institution in Liverpool founded at about the same time, have, in fact, become models for similar institutions in other countries—in France, Germany, Belgium, Italy, and in the United States of America. We may add that a volume on the life and work of Sir Patrick Manson, by his son-in-law, Dr. Manson-Bahr, and Professor Alcock, lately of the London School of Tropical Medicine, is now nearly ready for issue.

THE ANTIRACHITIC VITAMIN.

VARIOUS investigators have shown in recent years that irradiation of sterol-containing materials with ultra-violet light produces antirachitic potency, and it has generally been considered that the sterol itself (cholesterol or phytosterol) was the vitamin precursor. A paper has recently been read before the Biochemical Society in which the results of experiments carried out by Professor Heilbron, Dr. Kamm, and Dr. Morton (University of Liverpool) are described. These investigators have shown that by very careful fractional crystallization of so-called pure cholesterol a least soluble fraction can be collected, in which nearly all the vitamin precursor is concentrated. It is thus proved that the antirachitic properties developed in cholesterol on irradiation are not due to the sterol itself, but to the presence in it of a minute quantity of some other substance. This conclusion has been arrived at by experimentally following the concentration of the vitamin precursor by delicate spectrographic methods. Whereas cholesterol itself shows only general absorption in the ultra-violet region, the precursor has three well defined absorption bands which disappear on irradiation with concomitant vitamin production. The spectrographic results have been verified by direct animal feeding tests. The most concentrated fraction so far obtained has a potency over four times as great as the original material. Efforts are now being made, on the one hand, to obtain this substance in more concentrated form, while, on the other, cholesterol derivatives are themselves being examined spectrographically with a view to fixing possibly the precursor as one of these compounds.

THE FERENS INSTITUTE OF OTO-LARYNGOLOGY.

AN informal ceremony took place at the Middlesex Hospital on February 8th, when Mr. T. R. Ferens, lately member of Parliament for Hull, handed over to Prince Arthur of Connaught, chairman of the governing body, as representing the medical school of the hospital, a suite of laboratories which are to be known as the Ferens Institute of Oto-Laryngology. Mr. Ferens has founded this institute at a cost of £20,000. At present it is housed on the top floor of the recently provided annexe of the Middlesex Hospital in Cleveland Street, but as soon as the structural alterations at the main hospital are completed it will be housed in a new building. The accommodation consists of a large general laboratory, three smaller research laboratories, a museum and library, a dark room for photography, a lecture room, and a common room. The institute has been elaborately equipped with microscopes and all apparatus necessary for research in the physiology and anatomy and the diseases of the ear, nose, and throat, and is intended to be used for research and teaching under the direction of Mr. Somerville Hastings and Mr. F. J. Cleminson (the latter a relative of Mr. Ferens), respectively surgeon and assistant surgeon of the ear and throat department of the Middlesex Hospital. Mr. Ferens, in handing over the institute, said that he had been informed of the great need of research, particularly in connexion with the ear. He was arrested by the remark of one specialist that very little was really known about this organ. He expressed his great pleasure in making the benefaction. Prince Arthur of Connaught, in accepting the gift, said that the provision of such an institute was unexampled in the British Empire and perhaps in the world. Its purpose would be to offer the most complete and up-to-date facilities for research and teaching, and studentships would be provided for approved post-graduates who might desire to pursue investigations on the lines indicated, for from one to three years. Its total capacity would be for eight to ten students. There would be no charges for use of the laboratories and the apparatus and other essentials of research work, but, of course, students would have to provide for their own maintenance. It was also hoped to give opportunity in certain cases of exceptional merit for research work to be continued, in spite of the lack of financial resources, by a post-graduate student otherwise judged to be specially qualified for it, and with this object in view an appeal would be made for the founding of three such post-graduate studentships, of £300 each—one for Great Britain, one for the Dominions, and one for America. Money to endow these studentships had still to be provided, so that a good opportunity was offered for supporting Mr. Ferens in his far-seeing and public-spirited benefaction, which would help to make London the centre of study in diseases of the ear, nose, and throat for students from all parts of the world. Mr. Hastings pointed out that the institute was closely associated with the treatment of patients, that the out-patient department for such cases was on the floor below, and in the adjacent wards were twenty-six beds given over to the treatment of these conditions. Mr. Cleminson said that the name first proposed was the Institute of Otology, but as it was intended for the study of diseases of the nose and throat as well as of the ear, a more comprehensive title had now been chosen. He believed that the institute would form one valuable contribution towards making London the post-graduate centre in medicine. After the function was over Prince Arthur recalled the visitors to announce that Mr. Bernhard Baron, who was present, had expressed his willingness to establish the post-graduate studentship for Great Britain. Subsequently, in the hospital theatre, Dr. Logan Turner, President of the Royal College of Surgeons of Edinburgh, and Dr. A. de Kleijn of Utrecht, lectured on "The most recent physiology of the labyrinth."

MEDICAL EDUCATION IN THE SUDAN.

THE steady progress of medical and other education in the Sudan is illustrated in the annual report of the Gordon Memorial College for 1925. With the advent of more peaceful conditions the British troops were withdrawn from their occupation of some of the college buildings, and expansion of the work has now become possible. The primary section of the school has been closed, and room has thus been made for new laboratories for physics, chemistry, and biology. More space is also available for the important entomological section and the museums. The report contains an account of the work during the year at the Wellcome Tropical Research Laboratories, and mention is made of a proposal to build new medical research laboratories adjacent to the Civil Hospital. This would permit closer co-operation between the medical officers in the hospital and laboratories, would facilitate the examination of fresh pathological material, and provide a suitable teaching centre for pathology for the students of the Kitchener School of Medicine. If this proposal materializes, the director of the Sudan Medical Service has agreed to allot beds in the Civil Hospital to facilitate research. Another suggestion made is that a railway car should be equipped as a travelling laboratory, so as to serve Port Sudan and other towns of increasing size and commercial importance. A provincial laboratory has been established at Atbara, and the Gezira laboratory at Wad Medani research farm has been provided with chemical and entomological sections. The pathological museum has continued to expand, and valuable material has been collected for teaching purposes in the Kitchener School of Medicine, where various members of the staff have acted as lecturers during the year. In addition to the routine and educational work, various researches have been in progress, including those of Major N. T. Whitehead in connexion with the prevalent types of pneumococcus responsible for epidemic pneumonia, and investigations by Dr. D. Riding on bilharziasis and trypanosomiasis.

DRUGS AND THE CHEMIST.

THE year 1884 was given by Mr. Norman Evers, F.I.C., in a lecture last week at the Royal Society of Arts, as marking the turning point in the modern history of drugs. By that year practically all the important alkaloids had been discovered, and the era of production of synthetic drugs was beginning. Synthetic drugs from then onwards, in ever-increasing numbers, began to pour into this country, chiefly from Germany, until the great war temporarily put a stop to them. Mr. Evers showed a list of fifty important synthetic products which were introduced into this country between 1885 and 1914. The production of synthetic drugs, he said, had its origin in the search for an antiseptic which would be an improvement on carbolic acid, and in particular one which could be used internally as well as externally. The ideal antiseptic had yet to be discovered, but the search for it had led to many interesting and unexpected discoveries. A good deal of weeding out of synthetic drugs occurred during the war, and the lecturer thought that the medical profession was now definitely more sceptical than formerly, and that there was less likelihood of a drug of untried properties having any vogue. Mr. Evers said that even to-day the structure of some of the best known alkaloids, such as morphine, strychnine, and emetine, was still undecided. Many alkaloids had been synthesized, the most recent triumph being the synthesis of cocaine by Willstatter, but no alkaloid had yet been prepared synthetically on a commercial scale at a price at which it could compete with the natural product. The separation of glucosides, with the determination of their composition, and the isolation of hormones presented still greater difficulties. Adrenaline and thyroxine were the only hormones which had passed with anything like completeness through the three stages, which were first the crude extract, then the pure active principle prepared from the animal, and finally the synthetic product. Insulin and the pituitary, parathyroid, and ovarian hormones were still in the first of these stages. While the advent of new drugs had created new problems, the advances in chemical and physical science had enabled those connected with the older drugs to be tackled. Only a few years ago the preparations of ergot on the market were uncertain in their activity; there was no recognized and accurate method of physiological standardization, and no method of chemical standardization at all. The official method of preparation of the liquid extract, given in the *British Pharmacopoeia*, was one which was certain from its nature to produce an almost inactive product. But work had since been done on the chemical side of the isolation of the alkaloids, while on the physiological side a method had been evolved whereby the alkaloidal activity might be accurately tested, and now physiologically standardized liquid extract of ergot could be safely relied on to give the results expected of it. The analytical control of the supply of drugs had also been developed in recent years. Before 1880 there was very little standardization, and until twenty years ago the analytical control of the drug supply was practically confined to alkaloidal determinations and a few tests prescribed in the *British Pharmacopoeia*. To-day practically every drug that the pharmacist or medical man received, if it came from a firm of repute, had been checked by analytical methods, not only in respect to the finished product, but, perhaps two or three times, in respect to the raw materials. The progress of chemotherapy would necessitate the synthesis of compounds of increasing complexity. Modern therapeutics called for increased co-operation between pharmacologists, physiologists, and chemists, universities and research institutions, and chemical manufactories. Medical men and the public must be protected against the introduction of new drugs with exaggerated statements as to their efficacy, and the lecturer pictured what would have happened had the Medical Research Council not stepped in to ensure that insulin was properly manufactured and carefully standardized.

MEASUREMENT OF ULTRA-VIOLET RAYS.

WORKING in the research laboratory at Messrs. Cadbury's factory at Bournville, J. Ewart Moss and Arthur W. Knapp have revived the old method of measuring ultra-violet rays used by Freer in the Philippine Islands, and by others before Freer, in which a standard solution of oxalic acid and uranium acetate is exposed to the source for thirty minutes, and subsequently titrated with N/10 potassium permanganate. The standard solution, when of a thickness of 2.2 mm., absorbs all those radiations of wave-length shorter than 3,200 down to 2,300 A.U. It is comparatively unaffected by the "near" ultra-violet—that is, by wave-lengths longer than 3,200 A.U. The maximal biological action of the sun is in the rays between 3,200 and 3,000 A.U., and of artificial sources between 3,000 and 2,900 A.U. The standard solution is therefore a suitable one, and can be used for testing the falling-off of mercury vapour lamps, the transparency of glasses such as vitaglass compared with ordinary window glass, and for like purposes. This method is not so convenient to use as the acetone blue method introduced by Webster, L. Hill, and A. Eidinow, because titration is required. With the acetone blue method the standard solution is exposed in a standard silica tube, and the degree of fading measured directly against a set of standard tubes of decreasing depth of blueness. The degrees of this scale of measurement are biologically determined against erythema production in the white skin. The acetone blue solution has almost the same region of absorption of the ultra-violet

spectrum as the uranium solution, and therefore can be justly used for measurement of lamps, glass screens, and ultra-violet intensity of sunlight.

THE STRANGEWAYS MEMORIAL FUND.

WE announced recently (January 29th, p. 206) that a memorial fund was being inaugurated as an expression of the respect and gratitude which many must feel for the work of the late Dr. T. S. P. Strangeways of Cambridge. Absorbed in his unselfish scientific investigation, Dr. Strangeways was not able before his premature death to make adequate provision for his widow and seven children, five of whom are still being educated. A meeting to consider the best means of organizing an appeal was held at the house of the Royal Society of Medicine on February 2nd, when Dr. H. R. Dean, professor of pathology, Cambridge, presided. It was announced that the committee of the memorial fund had set itself to raise, before next autumn, sufficient money to ensure that the five sons of Dr. Strangeways should be enabled to continue their education on the economical lines which their father had planned. To achieve this result it will be necessary to call for widespread support, and as there are many old pupils and colleagues of Dr. Strangeways in London and other large centres it was agreed at the meeting, on the motion of Dr. W. S. A. Griffith, seconded by Dr. Paul Fildes, that copies of the appeal should be forwarded to the various medical schools so that they might be distributed to Cambridge men and others likely to be interested. Sir Walter Morley Fletcher, secretary of the Medical Research Council, in commending the appeal, spoke of the value of the research work undertaken by Dr. Strangeways, especially in connexion with rheumatoid arthritis; although he received a grant from the Council, Strangeways had spent large sums out of his own pocket in the furtherance of his beloved research. His work not only laid the foundation upon which others could build, but it enabled him to make a classification of the disease into various clinical types. This work on rheumatoid arthritis led him to an intensive study of tissue culture, and thence to the problem of cancer. One sign of the extreme value to medicine of the work which Strangeways had done, and was doing up to the time of his death, was the approval set upon it by the Medical Research Council as a contribution to scientific medicine. But that was only one part of the work done by Strangeways. Probably thousands of former students owed very much to his superb natural gifts as a teacher—gifts which were shown in their highest degree at the demonstration table rather than at the lecture. Many instances were remembered of his unselfish and thoughtful help for young people. Recognition of work of such a character as that undertaken by Strangeways was necessarily slow, and it would always be a matter of regret that he died before his work was fully appreciated, but the memorial fund would at least give the opportunity for posthumous appreciation. We may repeat that cheques should be drawn to Lloyds Bank, Cambridge, and crossed "a/c Strangeways Memorial Fund." They may be sent to the manager of the bank, Mr. G. F. C. Gill, or to Sir Humphry Rolleston (Southfield, Cambridge), or to Professor H. R. Dean, Dr. M. Donaldson, Dr. G. P. Bidder, Dr. L. E. Shore, or Dr. L. Cobbett.

INFLUENZA.

THE deaths from influenza in the great towns of England and Wales increased last week from 725 to 818, but in London the number decreased from 252 to 215. The recrudescence in London seems, therefore, to have passed its maximum. For the great towns other than London the totals for the last three weeks were 273, 473, and 603; the rate of increase appears to be slackening, but it is not improbable that some further increase will occur. However, it seems unlikely that the maximum will exceed 1,000 for the whole of the great towns (including London). Widespread as the illness has been, the toll taken in lives has been much below that of the recrudescence in 1922. In the week ending January 28th of that year 1,450 deaths were registered in the great towns. The Scottish Board of Health states that reports received down to February 5th show that in most parts of Scotland there was no undue prevalence of influenza for the time of the year, and that there was nothing in the nature of an epidemic. There is, however, a good deal of influenza of a mild catarrhal type, and in some places—Aberdeen, Greenock, Falkirk, and the Lower Ward of Lanarkshire—there is rather more than there was a week ago. At Aberdeen about 3 per cent. of persons visited by health visitors had influenza, and about 60 per cent. of health insurance sickness benefit claims had reference to influenza cases. In other places—Dundee (where, however, there was an increase in the number of deaths from influenza and from respiratory diseases), Motherwell and Wishaw, Dunfermline, Fifeshire, and the Upper and Middle Wards of Lanarkshire—there were fewer cases than in the previous week. In Motherwell and Wishaw the type is said to be becoming milder, and the interesting distinction previously reported by the medical officer of health, that the symptoms of the Wishaw cases were mainly gastric and those of the Motherwell cases catarrhal, is becoming less marked.

POST-GRADUATE TOUR TO AMERICA.

A POST-GRADUATE tour in Canada and the United States of America is being arranged by the Section of Surgery of the Royal Society of Medicine. It is proposed that, starting on July 23rd, the complete tour shall occupy about six weeks. The towns to be visited are: Boston, New Haven, New York, Philadelphia, Baltimore, Washington, Cleveland, Detroit, Ann Arbor, Grand Rapids, Chicago, Rochester (Mayo Clinic), Great Lakes, Niagara, Toronto, Ottawa, and Montreal. Facilities will be available for shortening the tour for those who so desire, and arrangements will be made for those interested in other subjects than surgery. The cost of the whole tour is estimated at about £140, and travelling facilities on the same terms will be offered to the wives of those taking part in it. Fellows of the society other than members of the Surgical Section can participate in it on being nominated by the Tour Committee, and the Section is willing to permit members of the medical profession who are not Fellows of the society to accompany them, if nominated by two members of the Section and approved by the Tour Committee. Those who wish to join this tour are asked to communicate as soon as possible with Mr. C. Max Page, 134, Harley Street, London, W.1.

THE Milroy Lectures, the first of the courses of the Royal College of Physicians this session, will be given by Dr. W. F. Dearden, medical officer of health to the Manchester Port Authority, on March 1st, 3rd, and 8th; his subject is health hazards in the cotton industry. The next course, the Goulstonian Lectures, on cardiac dyspnoea, will be given by Professor F. R. Fraser, M.D., of St. Bartholomew's Hospital, on March 10th, 15th, and 17th. The Lumleian Lectures, which will be delivered on March 22nd, 24th, and 29th by Sir Charlton Briscoe, Bt., M.D., physician to King's College Hospital, will deal with the muscular mechanism of respiration and its disorders. In May (3rd and 5th) Dr. C. Gordon Douglas, C.M.G., F.R.S., of Oxford, will give the Oliver-Sharpey Lectures, on the co-ordination of the respiration and circulation with variations in bodily activity. Lastly, the Croonian Lectures will be given in June by Sir F. Gowland Hopkins, M.B., D.Sc., F.R.S., professor of biochemistry in the University of Cambridge; his subject is the task of biochemistry.

LISTER CENTENARY CELEBRATION IN EDINBURGH.

BRITISH MEDICAL ASSOCIATION ANNUAL MEETING, JULY, 1927.

A PUBLIC meeting in celebration of Lord Lister's centenary is to be held in the McEwan Hall, Edinburgh, on Wednesday, July 20th, at 8 p.m. The Right Hon. the Earl of Balfour, K.G., O.M., has consented to take the chair, and short addresses will be delivered by Sir William Watson Cheyne, Bt., Professor Tuffier of Paris, Professor Harvey Cushing of Harvard University, and Dr. James Stewart of Halifax, Nova Scotia.

Throughout the week of the Annual Meeting of the British Medical Association a museum of Lister relics will be on view in the Upper Library of the Old University. In this connexion most generous assistance has been given by the director of the Wellcome Historical Medical Museum, London, and his staff, and the unique interest of the exhibits will largely be due to their co-operation.

Lister Memorial Volume.

A Lister Memorial Volume has been prepared, and with the consent of the Council of the British Medical Association it will constitute the Book of the Meeting in so far as a copy will be presented to each member of the Association who registers. The volume, edited by Dr. Logan Turner, contains a variety of contributions; a sketch of Lord Lister's life is given by his former house-surgeon, Sir George Beatson of Glasgow. A series of short personal reminiscences has been written by Sir William Watson Cheyne, Dr. Rutherford Morison, Dr. Grasett, Dr. Baldwin, Dr. T. R. Ronaldson, the late Professor Francis Caird, Dr. Stewart (Halifax), Dr. Douglas (Cupar), and Mr. Hamilton Russell of Melbourne. Two of Lister's scientific addresses, and a series of letters of general interest, are incorporated in the book. A number of striking comments which he made at various times in relation to the germ theory and the antiseptic system, and, in fact, upon things in general, have been grouped in a chapter under the heading "Obiter dicta." A section of particular interest is that dealing with the lives of Lister's fellow residents in the Edinburgh Royal Infirmary during the summer of 1854, a group which included Beddoe, Christison, and Kirk—men who won distinction in widely differing fields. This chapter has been contributed by Dr. Logan Turner. A chapter entitled "Surgery prior to Lister's time" is written by Mr. Alexander Miles, while an article on the influence of Lister's work on surgery is contributed by Professor Fraser; Professor Sharpey-Schafer deals with Lister's work as a physiologist.

The volume, which will contain from 180 to 200 pages quarto, is illustrated, and, except in so far as reproduction of certain letters and published articles is concerned, the matter is original.

Lister's Edinburgh Residences.

The residences which Lister occupied while in Edinburgh have hitherto been undistinguished by any memorial inscription. The committee considered the present a suitable opportunity to remedy what may have seemed to many an omission. With the generous consent of the proprietors concerned, short indicatory inscriptions are being placed upon the wall of 11, Rutland Street, and 9, Charlotte Square.

Prize Essay.

A donation of £25 was received by the committee, the donor desiring that this sum should be awarded as a prize for the best essay submitted on the subject "The influence of Lister on surgery." To the original prize the committee has added a gold medal, and this award is open to students and graduates of not more than one year's standing of any medical school in the British Empire. The terms upon which the essays are to be submitted have already been published, and notices have been sent to the various teaching centres. It is intended that the award of the prize and medal shall be made by Lord Balfour at the Lister centenary meeting on July 20th.

AN OUTBREAK OF ANTHRAX AT THE ZOOLOGICAL GARDENS.

Report by H. HAROLD SCOTT, M.D., F.R.C.P., *Pathologist to the Zoological Society of London.*

THREE weeks ago we were able to give a short preliminary account of the outbreak of anthrax among elephants at the London Zoological Gardens. We are now in a position to print the following extract from the report made by the pathologist, Dr. H. H. Scott, to the Prosectorial Committee. We are indebted to that committee and Dr. Chalmers Mitchell, secretary of the society, for placing the text at our disposal. It fully confirms the main facts stated in our note published on January 22nd (p. 154). It would appear that the disease was not suspected by anyone until the death of the second elephant, and that the precautions adopted with regard to the men who had been in contact with the elephant that died first were taken because of the diagnosis of anthrax in the second elephant. The Zoological Society and its officers are, we think, to be congratulated, not only on the prompt and effective handling of the outbreak, but on the frankness with which they have presented full and authoritative details to the medical profession. After stating that a detailed account of the *post-mortem* findings can be seen, by anyone interested, in the full autopsy records in the custody of the society, Dr. Scott continues as follows:

The blood was dark and unduly viscid, but the muscles did not show any unusual discoloration. The spleen, though congested and very dark, was not enlarged. The other organs, except for a somewhat darker coloration of the contained blood than was normal, revealed no appearance worth noting.

From the first case, "Indiarani," smears were taken from the heart blood, the peripheral blood, the liver, spleen, kidneys, and lungs, and cultures were put up also from each of these, and as the liver on section showed a foaminess which was expected to be due to Welch's *Bacillus acrogenes capsulatus*, the cultures were set up in duplicate and incubated aerobically and anaerobically. Portions of the liver, spleen, and lungs were also taken for histological examination. All the smears showed large, rather square-ended bacilli, and the fact that the anaerobic cultures grew well, while the aerobic showed no growth, led me to infer at the time that the *B. acrogenes capsulatus* was the cause of the condition. I have heard since, both from Professor Wooldridge and others, that the gas gangrene bacilli very rapidly kill out the *B. anthracis*, with the result that the latter do not grow in the presence of the former. Thus is accounted for the fact that Welch's bacillus, an anaerobe of the gas gangrene group, developed to the exclusion of the other.

On December 29th the second elephant, "Sundermalah," died, and the autopsy was undertaken as soon after as possible; in fact, the body was quite warm. The *post-mortem* examination was started just after 9 a.m. With the exception that there was absence of the foamy state of the liver, the conditions found were on all fours with what had been noticed in the former case, but, in addition, on the internal aspect of the right elbow there was a sore covered by a scab; on removal of this scab I made smears from the tissues beneath, and also smears from the blood and the various organs and tissues, as in the case of "Indiarani." Cultures were also put up. These were made between 9 and 11.30 a.m., and taken over at once to the laboratory, where the smears were stained and examined and the cultures placed to incubate, aerobically and anaerobically.

The smears showed numerous bacilli, so suspicious to my mind of anthrax that I communicated the fact to the superintendent, and then telephoned to Professor Leiper, to whom some worms and faeces had been sent, telling him of my suspicions, in order that the material might be burnt or otherwise disposed of before anyone in his laboratory ran the risk of infection.

Professor Wooldridge, being at the Gardens the same afternoon, came over with Dr. Vevers and examined my smears. He did not regard them as sufficiently characteristic of anthrax, being, as he said, too large and not quite typical in shape. Though expressing his doubts, he suggested that he should take some smears down to Sir John McFadyean to confirm or refute my suspicions. He accordingly went with me to see the body, and remarked that there was not the usual discoloration of the muscles associated with anthrax—a point we too had noticed;

but for safety I made some fresh smears of the blood for him to take to Sir John McFadyean. Later I received word of confirmation from Dr. Vevers, who said he had heard of the fact from Professor Wooldridge. The following morning the cultures showed unmistakably the nature of the infection, and confirmed still further my suspicions of the smears. To be brief, the tissues, which have now been cut and stained, show the condition very clearly.

To finish with the question of the elephants first. In neither case did the intestine show any inflammation at all, and the probability of their having been infected by mouth was slight; sections of the liver, moreover, show clearly that the portal veins contain practically no bacilli, whereas the branches of the hepatic artery are crowded with them. This, I think, can only be explained by the fact that the systemic vessels carried the infection from the skin or the lungs, and not that the infection gained entrance through the alimentary tract.

In spite of the absence of signs of intestinal infection, Dr. Vevers suggested that the oilcake supplied to the elephants should be examined bacterially. It was quite possible that, if infected, the oilcake might be trodden upon and crushed, and any surface wound become infected by the animals lying on it. In neither case was there any sore found on the feet, which were carefully examined. Several cultures were put up from the oilcake and from the box in which the cake was kept, but with negative results.

On January 1st cultures were made from fissures in the skin of the remaining five elephants, on the slender chance of finding a local infection in any of them, but all proved negative, and all are well at present. The next suggestion, for which also I am indebted to Dr. Vevers, was that the "pig-oil" with which the elephants are rubbed from time to time (and they had in fact been rubbed on December 18th) might be contaminated. Cultures were therefore put up from the few drops remaining in the tin which had been used, and also cultures from a fresh tin opened for this purpose. The second proved to be quite sterile, and from the first no harmful organisms were grown, merely such as might gain entrance from exposure to the air. There were no anthrax colonies. Another culture, put up later, merely confirmed these findings.

So much for the elephant side of the question. By December 31st all we could state definitely was that the second elephant, "Sundermalah," had died from anthrax: the case against the first being the same was possible, but not proven.

Turning now to the human aspect. On December 30th, in view of the results of the examination of the smears from "Sundermalah," and of the cultures, all those who had been in contact with either of the cases were examined for cuts, sores, etc. P., B., and L. were found to have small cuts or fissures on their hands, and W. a spot (? acne) on the face. Smears and cultures were put up from these. From P. there grew colonies of *Staphylococcus albus* and *Staph. aureus*; from B. and L. colonies of *Staph. albus* only; from W. colonies of *Staph. albus, aureus,* and *citreus*.

On January 3rd, 1927, B. returned with a sore on the wrist (having started, it appears, in a hair follicle). This was a papule becoming vesicular with a haemorrhagic periphery, the whole rather smaller than a threepenny piece. A culture was taken from this and also a smear made. The latter showed anthrax bacilli on staining. He was sent to hospital, and the culture, which had grown abundantly by the following day, was sent, on the instructions of Colonel Monckton Copeman, F.R.S.,[1] to Dr. Arthur Eastwood, the bacteriologist of the Ministry of Health, who later wrote to me confirming the fact of its being the suspected *B. anthracis*.

B. had not come into contact in any way with the second elephant, only with the first—"Indiarani"—thus affording proof that the first case had been one of anthrax and replacing our suspicion by certainty. He had first noticed the spot on December 30th or 31st, thus giving the incubation period of six to seven days.

On January 5th Mr. W. Lawrence, my assistant, who had a great deal to do with the second autopsy (December 29th), called attention to a small red spot on his arm which he had noticed the previous evening (January 4th). There was a second similar spot about three inches above this; both were hair-follicle lesions. Serum from these was examined by smear, which revealed the *B. anthracis*, and cultures put up showed abundant growth the following morning. He also was sent to hospital, and, a subculture having been taken, the original was sent to Dr. Eastwood, who again confirmed our work. The incubation period from the date of the second autopsy was again six days.

On the same day (January 5th) G., the boy who came to cart away the remains of the bodies, presented himself with a sore on his arm which had appeared on the previous day. When seen by me it was very small, hardly larger than a hempseed, and had a slight ring of oedema (whether this was part of the actual lesion itself one cannot say; he said that he had been "squeezing the place that morning"). Smears from it showed bacilli in considerable numbers, giving the characteristic picture by McFadyean's method of staining, and the boy was sent to hospital; the culture confirmed the smear the next morning.

On January 6th Mr. F., who works for Mr. G., came up complaining of a "boil" on his right forearm which he had had for the previous "two or three days." There was a definite lymphangitis extending from this up the arm, and the site of the inflammation was painful (the "spots" in the other three were, so the patients said, quite painless). Smears taken from the serous discharge at the edge of the cellulitis showed only staphylococci and streptococci, but for safety a culture was put up and he was given an injection of anti-anthrax serum. The following morning there was a growth of staphylococci and streptococci, and *B. anthracis*, and this patient also was sent to hospital.

There have been no further cases, to my knowledge, either among the human contacts or among the animals.

CONCLUSIONS.

The investigation is of particular interest as showing:

1. That infection may so readily occur via a hair follicle, when all care has been taken to seal cuts, fissures, or more open wounds. (In this connexion I may mention that the second assistant, C., gave himself a fairly deep cut on the occasion of the second autopsy, but this was treated at once, and he has shown no signs of any infection.)

2. That the incubation period is six days, as evidenced by two of the cases definitely, while G.'s arose six days after contact with the second elephant. In F.'s case nothing can be inferred, he was working at Mr. G.'s, and might have become infected at any time after the death of the first elephant.

3. That the initial sore is quite painless, and in the earlier days might easily be overlooked.

There still remains the mystery as to the source whence the elephants themselves became infected.

[1] After the diagnosis of anthrax had been confirmed the case was reported to the Ministry of Health, who delegated Colonel Monckton Copeman to take charge from the point of view of public health. [Secretary, Zoological Society of London.]

Nova et Vetera.

DR. JOHN LEYDEN, ORIENTALIST.

ONE of the accusations brought against the old East India Company was that it sometimes put square pegs into round holes and not infrequently showed favouritism. One instance that has sometimes been quoted is that of the Orientalist, John Leyden, and even his biographer, Thomas Brown, seems to admit the truth of the accusation.[1] It is true that Leyden had never seriously studied medicine, but he had attended some classes during the three years previous to his appointment to India, with a vague notion of taking up medicine if both the Church and literature failed him.

John Leyden, who was born in 1775, entered Edinburgh University at the age of 15, and after completing his arts course joined the divinity classes in 1793, went to St. Andrews in 1797, and was ordained licentiate of the Church of Scotland in 1798. He met with no great success as a preacher, but was more successful in literature; he collaborated with Scott in the production of *Border Minstrelsy*, and did much other miscellaneous literary work, including the compilation of a history of the exploration of Africa, published in 1799. Reading accounts of the travels of Mungo Park (an ex-surgeon of the East India Company), he was fired by the desire to imitate him, and applied to the Sierra Leone Company. His friends, however, persuaded him that he would find greater scope for his linguistic talents in the East, and made interest with

[1] We take the particulars on which this note is founded from Thomas Brown's *Memoir* prefixed to Leyden's poems (Nimmo, London and Edinburgh, 1875) and from official records.

Henry Dundas, President of the Board of Control (created Lord Melville in 1802), for an appointment in the Company's service. The only appointment for the year remaining unallotted was one as assistant surgeon in Madras, and the nomination to this was promised to Leyden if he could succeed in qualifying within six months. After six months' hard study he got the diploma of L.R.C.S.Edin., and obtained also the degree of M.D. from the University of St. Andrews. Leyden had already shown his capabilities as a linguist, and nowadays if he went to India would probably have been provided for in the Educational Service; but a century ago the only way in which the Company could employ a candidate was by giving him either an appointment in its covenanted civil service or a commission in the army, and the latter included the medical department.

Leyden's commission was dated by the Court as of season 1801, but he only received orders to start for India in January, 1803. He was to have sailed in the *Hindostan*, but was taken ill in London and missed his passage, fortunately for himself, for the ship was wrecked a few days after starting, with considerable loss of life. Leyden finally left England in April, 1803, and reached Madras in August, 1803. He was posted to the Presidency General Hospital, to which all assistant surgeons were sent on arrival, and the period there spent was one rather of pupilage for the study of tropical disease and of the vernacular than of practice. In 1804 he was appointed surgeon and naturalist to the commission deputed to survey Mysore and Travancore. Falling seriously ill with fever and liver disease while so employed, Sir John Malcolm, the Resident of Mysore, kept him for some time in his house, till he was strong enough to be sent down to Madras, whence he went for a sea voyage to Achin and Penang for the recovery of his health. After some months at Penang he was sent, early in 1806, to Calcutta, where he spent more than a year engaged solely in language study. In 1807 he was appointed professor of Hindustani in the College of Fort William, where the newly arrived civilians were then instructed in Indian languages, law, etc. In 1808 he was appointed judge of the 24 Parganas, the metropolitan district surrounding Calcutta. This post, however, appears to have been of an executive rather than a judicial nature, for he wrote of himself as employed at this time chiefly in hunting down robbers. In the following year he was appointed one of the Commissioners of the Court of Requests in Calcutta, and in 1810 became Assay Master of the Calcutta Mint, where he had as his assistant one destined to surpass even his own fame as an Orientalist, H. H. Wilson, who subsequently succeeded him as Assay Master.

It seemed as though Leyden's genius for languages was now to have full scope. But when an expedition was sent to reduce the Dutch settlements in Java, Lord Minto, the Governor-General, took Leyden with him as interpreter. They sailed from Calcutta on March 9th, 1811, and landed in Java on August 4th. Batavia surrendered on August 7th. Leyden, while examining manuscripts in a damp unventilated room, contracted fever, of which he died on August 27th, a few days before completing his 36th year.

While at Penang in 1805 Leyden compiled a "Dissertation of the languages and literature of the Indo-Chinese nations," which was published in *Asiatic Researches*, vol. x (1810). He also translated *Malay Annals*, published in 1821, ten years after his death; and for the British and Foreign Bible Society made translations of the Gospels into Pushtu, Baluchi, Macassar, Maldivian, and Bugis. His most important work, however, was the translation from Turki of the *Memoirs of Babar*, the first of the great Mogul emperors; this work he did not live to finish, and it was completed by William Erskine. Doubtless, if he had been spared for further usefulness, he would have accomplished far more philological work. As it is, he left but little behind him in comparison with his great powers and high reputation. He is now almost forgotten. His fame, such as it is, rests chiefly upon his earlier poetical work, written before he left Scotland, his chief poems being the series called *Scenes of Infancy*.

THE FOUNDLING HOSPITAL SITE.

WE are informed by Dr. W. M. Fairlie (9, Mecklenburgh Square, W.C.1) that the following letter has been addressed to the Ministry of Health by a number of medical practitioners resident in the area affected by the proposal to transfer Covent Garden market to the site of the Foundling Hospital. In addition to the gardens of the hospital the estate contains several squares, which afford very welcome air spaces in that part of London. As we pointed out some months ago, evidence that the problems of Covent Garden have yet been sufficiently analysed by the appropriate persons is wanting. No doubt the trade has outgrown the present market, but the places from which the produce sold there come have not been considered adequately in relation to the best possible site. It is probably true that much of it is brought from the counties west of London, but this should be definitely ascertained. Nor is the public fully informed as to the railway depots in London to which produce from abroad is consigned. In any case it must reach Covent Garden by wagon or lorry. This makes it all the more important that in fixing the new site consideration should be given to the demand for lessening the congestion of traffic generally in London.

9, Mecklenburgh Square,
London, W.C.1,
5th February, 1927.

To THE RIGHT HONOURABLE NEVILLE CHAMBERLAIN, M.P., *Minister of Health.*

Dear Sir,

We, the undersigned medical men and women residing on the Foundling Hospital Estate, view with grave concern the growing tendency to build over the open spaces in the centre of London. Endsleigh Gardens and Mornington Crescent have already been sold for building purposes, and a bill is to be introduced in Parliament in the ensuing session with the object of obtaining power to erect a market on the grounds of the Foundling Hospital and the adjoining squares.

This site is largely surrounded by thickly populated areas, and in its immediate vicinity are no less than seven important hospitals. Any diminution of the open spaces in this neighbourhood is bound to have an adverse effect on the health of the community.

Open spaces, by acting as natural ventilators of the surrounding streets, diminish the incidence of infectious disease. In London they have undoubtedly exercised a considerable influence in producing a low death rate and a general high standard of health. In this connexion it is worthy of note that the children of the Foundling Hospital have been, over many years, extraordinarily free from tuberculosis, no definite case having occurred during the past decade.

We would respectfully urge your consideration of the matter, and venture to suggest that the permanent preservation of the squares of the Foundling Hospital Estate would be a measure in the best interests of public health, and one which we earnestly hope may receive the sympathetic consideration of the Government.

We remain, Sir,
Your obedient servants,

C. T. BISHOP, M.B.

Scotland.

MATERNITY AFFAIRS IN SCOTLAND.

AT the annual Committee of the Convention of Royal Burghs in Edinburgh on January 26th, it was reported that a deputation which waited on the Scottish Board of Health had been informed that the Royal Commission had contemplated the maternity services being administered by the local authorities along with other medical services, and that the Government was still considering the matter. Sir Henry Keith said that many of the women treated in homes under the control of local authorities had given a mandate to the authority to recover from the approved society the expenses of treatment up to the amount of

maternity benefit. In some instances these mandates were honoured by the societies, in others payment was refused. At the annual meeting of the Scottish Midwives Association on January 22nd it was stated that if the recommendation of the Royal Commission on National Health Insurance, for the wide extension of maternity benefit, including the payment of the certified midwife and maternity nurse from insurance funds, had become a statutory enactment, a vastly improved economic status for midwives would have resulted. In consequence, however, of the passing of the Government's Economy Bill, midwives had been deeply affected by the economic distress of the past year. Representations to the Scottish Board of Health had secured a grant in aid of short residential post-graduate courses for practising county midwives, and lectures and clinics for city midwives were increasing in numbers.

WELFARE OF THE BLIND.

The Scottish Advisory Committee on the Welfare of the Blind, set up in 1918 to advise the Scottish Board of Health on matters relating to the care and supervision of the blind in Scotland, has now issued its third report. It appears that there are in Scotland 6,639 blind persons on the central register, an increase of 585 since the issue of the last report in 1924; the increase, it is said, is to be explained by the greater interest now taken in matters connected with the blind. Of the total number of registered blind persons, 359 were under 16 years of age and 2,835 between 50 and 70. The committee estimates that 2,000 persons are now in receipt of the pension to which blind persons become eligible at 50. The number of blind children under 5 years of age has diminished from 15 in 1924 to 11 in 1926. The sum of £83,902 has been paid by the State in the past seven years towards the maintenance of services provided by voluntary agencies for the welfare of the blind in Scotland. The report describes in considerable detail the technical training of the blind, for whom bootmaking has been found specially suitable. The committee is of opinion that there should be no age limit beyond which training may not be commenced. The committee is not satisfied that the 288 blind persons certified or certifiable as mentally defective represent the true position; it believes that mentally defective blind children could be better dealt with and educated in schools for the blind among pupils of a higher grade of intelligence than they can be in institutions for mental defectives. With regard to marriages between blind persons, the committee believes that these are generally undesirable and should be discouraged as much as possible.

ABERDEEN ROYAL INFIRMARY.

The annual report of Aberdeen Royal Infirmary for 1926 shows a total of 4,664 admissions to hospital (1,016 medical and 3,648 surgical) during the year; 21,916 out-patients had received advice and treatment, and the total number of patients treated in the year showed an increase of 2,458 over those for 1925. The ordinary income was £31,856, and the ordinary expenditure £32,276. The ordinary expenditure had risen by £1,328, the increase being due to the larger number of beds occupied and also to the increased price of coal, which of itself had caused an expenditure of £855. The extraordinary income showed undestined legacies of £10,904 and bequests of £10,500 for permanent endowment. After allowing £2,751 for special expenditure on extensions, alterations, and improvements, an addition of £7,752 had been made during the year to the credit of the extraordinary income and expenditure account.

LEITH WAR MEMORIAL.

A new wing was opened at Leith Hospital on January 29th by Sir John Gilmour, Bt., Secretary of State for Scotland, as the Leith memorial to those who fell in the war. Ex-Provost John A. Lindsay, chairman of the War Memorial Committee and of the Leith Hospital board of managers, who presided over a large gathering, said that when the subject of a memorial to the men who fell in the war was first considered many suggestions had been made, but the proposal to provide accommodation for sick children in Leith Hospital by means of a special wing speedily obtained general approval. In a comparatively short time £30,000 had been subscribed. Shortly after this a gift of £20,000 towards the project had been received from Mr. John W. Hope, a London merchant who had started business in Leith, so that the required total of £50,000 had been very quickly reached. Sir John Gilmour, in declaring the memorial open, said that it was peculiarly interesting to find that in Leith they had decided to do something to help to solve what was one of the great national problems. He thought that a very suitable tribute to the dead was offered in the form of service to the living and to future generations. It was within the capabilities of every individual to contribute to the solution of the hospital problem. Mr. Thomas Cowan, in proposing a vote of thanks to Sir John Gilmour, said that the new children's wing meant a material increase in the hospital's annual cost of maintenance; before the war it had averaged £6,000 to £8,000, the present cost was £17,000, and to maintain the efficiency of the enlarged hospital a future annual expenditure of £20,000 would be required. He believed that the spirit of giving would be greatly encouraged if the Government were to free all legacies for hospitals from death duties, as the Hospitals Commission had recommended. Were this done it would help to stem the demand made by many people that the Government should maintain all such hospitals and institutions. Sir John Gilmour, when returning thanks, promised to pass on the suggestion to the proper quarter. He believed, however, that, above all, hospitals must not lose the private interest which had been the life of the community and of hospitals in the past. The new wing is a two-story building containing thirty-six cots and, with the necessary extension of the nurses' home, has cost about £40,000. This leaves a considerable sum available as an endowment fund for the maintenance of the wing.

CHAIR OF BOTANY AT ST. ANDREWS.

At the half-yearly meeting of the General Council of the University at St. Andrews, when Principal Sir James Irvine presided, a draft ordinance framed by the University Court for the establishment of a university chair of botany was considered. In 1889 a sum of £6,000 was given to University College, Dundee, for the establishment of a chair of botany in that college. This chair was held by Professor Patrick Geddes till his retirement in 1920. A further sum of £1,000 has since been received, and the Carnegie Trust had given £10,000 towards the endowment of a lectureship in botany in the United College, St. Andrews. It was suggested that the three endowments should be combined to form the basis of a practicable sum for a full university chair of botany. The professor would take part in the teaching of botany both at Dundee and St. Andrews. This recommendation was unanimously adopted and the draft ordinance approved. At the same meeting it was pointed out by the chairman that for the winter session 1926-27 there were forty-eight more students attending St. Andrews University than there had been at the corresponding time last year. This was in accordance with an upward movement in numbers at the other Scottish universities.

SMALL-POX IN FIFESHIRE.

A case of suspected small-pox was reported at Burntisland on January 29th. The case was that of a seaman on board the Dutch tug *Humber*, which had arrived from Devonport with the obsolete battleship *King George V* in tow. This tug and another, having left their charge at Rosyth to be broken up, proceeded to Burntisland to coal, and there the case of small-pox was discovered and taken to the fever hospital. The remainder of the crew were vaccinated, and their clothing and the ship were disinfected, while all possible local contacts were traced and examined. The local authority has recommended general vaccination in Burntisland and offered to carry it out free of charge.

EDINBURGH ROYAL PUBLIC DISPENSARY.

The work of the Royal Public Dispensary, Edinburgh, has been conducted from the same building since the year 1776. It was the first dispensary established in the city, and owed its origin to the enlightened conception and energy of Dr. Andrew Duncan. He was led to establish it by his conception of the needs of the poor, and by his recognition of the opportunity it would afford for practical training in medicine and pharmacy. As the city extended, other dispensaries upon similar lines were instituted, and have formed a very important part of the Edinburgh Medical School. During the past year some 1,500 cases visited the dispensary for the first time, while the Municipal Child Welfare Clinic associated with the dispensary continued to do valuable work, and has been attended by 245 new and 1,488 old cases. The total income for the year was £1,080, and as the expenditure had been £1,005, the accounts closed with a credit balance of £77.

England and Wales.

THE LONDON COUNTY COUNCIL PUBLIC HEALTH DEPARTMENT.

THE London County Council has decided to rearrange the medical work of its public health department. During the last three years the work has been organized in four divisions: (1) general public health (including diagnosis of small-pox, plague, and cholera); (2) inspection and treatment of school children (including infectious diseases of school children); (3) tuberculosis, venereal diseases, work under the Midwives Acts, and infant life protection; (4) mental deficiency and medical examinations. Each of these divisions is in charge of a senior medical officer. This arrangement has been found to result in undue pressure on heads of divisions, and to be ill adapted for the absorption of new work which from time to time devolves upon the Council. The necessity for some modification of the existing organization which will make for greater efficiency in the performance of the work connected with the control of infectious diseases has impressed itself upon the Public Health Committee. At present the bacteriological laboratory is attached to the second of the divisions mentioned above, but the scope of its work has steadily widened of recent years and can no longer be regarded as mainly confined to the control of infectious diseases in schools. The whole of the work, both clinical and administrative, relating to infectious diseases will be co-ordinated and placed in a new division under the direction of a senior medical officer. The medical work of the department will then be reorganized in five divisions, and will form a framework into which future accretions of work can, it is hoped, readily be fitted. At present there are five positions of senior medical officer on the fixed staff, three carrying salaries of £1,000 rising to £1,300, one of £900, rising to £1,100, and one of £800, rising to £1,000, in each case by an annual increment of £50. Under the new scheme the work of the five divisions will be so arranged as to give equal value to each of the salaries of these five officers; they will all be on the basis of £1,000, rising to £1,300. The Council is also proposing to extend the school medical service during the next triennium by additional dental and minor ailments centres, extension of provision for in-patient treatment of children operated upon for enlarged tonsils and adenoids and for children suffering from ear disease, further provision for bathing children and cleansing the verminous, increased medical services in connexion with open-air schools, health classes, mental defectives and delinquent children, and medical services in connexion with rheumatic children. Amendments have been tabled by Dr. Stella Churchill and by Mrs. Dalton, calling respectively for still further provision for medical services in connexion with rheumatic children and for dental and minor ailments work.

POST-CERTIFICATE SCHOOL FOR MIDWIVES.

The Minister of Health on Tuesday afternoon opened the new building of the Post-Certificate School of the General Lying-in Hospital, York Road, near Waterloo Station. The building, the gift of an anonymous donor, is situated at some distance from the hospital at Southampton Street, Camberwell. Dr. John S. Fairbairn presided over the opening ceremony, which took place in the conference hall of the new building, the other portion of which comprises an ante-natal clinic and certain accommodation for the superintendent, which, incidentally, enables the school to take extra pupils. Mr. H. W. Lydall, the solicitor on behalf of the donor, presented the new building to Sir Francis Champneys, president of the Lying-in Hospital, who, in accepting the gift, expressed the great gratitude felt towards the donor by all connected with the institution. He thought that when the history of midwifery in England came to be written, that presentation would form the beginning of a very important chapter. The idea of carrying the instruction of midwives into the time when they were actually practising was most excellent, and there was no reason why it should not be copied in other parts of the kingdom. Sir Francis, before calling upon the Minister of Health, reminded those present that there was someone else to whom gratitude was due—namely, Dr. Fairbairn, a man of enterprise and public spirit of whom they were all justly proud. In declaring the new building open Mr. Neville Chamberlain said it so happened that that was also the opening day of another institution (Parliament) with which he was connected, one which perhaps made more noise, though in some respects it was not unlike the school of which the new building formed part. In the other institution of which he was a member there were many little infant measures which, having been conceived, came to birth. Some were stillborn; some led a precarious existence after difficult labours, whilst others, more fortunate, grew up into strong, healthy Acts of Parliament. He personally had acted as accoucheur on a good many occasions. The interest of the building he was opening lay in its connexion with the Post-Certificate School. He believed the opportunity afforded to practising midwives to bring their practice up to date and acquire a knowledge of modern methods of midwifery was of real value and importance to the country. Even doctors might derive benefit if from time to time they could come from more remote parts of the country and see what their brethren in the great centres were doing. It was astonishing how recent were some of the ideas as to what midwifery practice should be. In 1916 three months' training was regarded as sufficient for midwifery practice in this country. Even the twelve months' training laid down in 1926 was a good deal behind the standard of some Continental countries, in which two years' training was necessary for midwives. It was a significant fact that those county nursing associations which had sent midwives to the school to be trained were so delighted with the results that they had been anxious to repeat the experiment. Mr. Chamberlain added that, whilst it was a great feat to have halved the infant mortality rate in a quarter of a century, it should not be forgotten that the maternal mortality rate showed at present very little sign of change. The most hopeful way of reducing the maternal mortality rate was by improving the midwifery service, and, thanks to the anonymous donor, it was possible to add still further to the services which the school was rendering to the community. As Minister of Health, and with a proper sense of responsibility, he thought it not only a great work but a great example, and one which he hoped would be duly noted, not merely by the county nursing associations, but by other institutions having facilities for training midwives.

ROYAL EAR HOSPITAL, LONDON.

The new buildings of the Royal Ear Hospital, London, were opened by the Minister of Health on February 9th. The hospital, which originally occupied premises in Dean Street, was amalgamated with University College Hospital in 1920. Through the generosity of Mr. Geoffrey Dureen, who has provided the whole of the necessary £75,000 as a memorial to his father, Mr. Henry J. Dureen, the new buildings have been erected in Huntley Street, close to University College Hospital, with which it is connected by a subway. The buildings are thoroughly equipped for the study and treatment of diseases of the ear. The operating theatre is on the third floor, and a silence room has been

made in the basement; its walls, floor, and ceiling have been so constructed as to be impervious to external sounds. Mr. Chamberlain was received on his arrival by the vice-chairman of University College Hospital, Lord Oranmore and Browne, and by the chairman of the Royal Ear Hospital, Mr. Geoffrey Duveen. In the course of a short address Mr. Chamberlain said that in 1925 more than 6,000 children attending elementary schools were either wholly or partially deaf within the meaning of the Education Act. In addition there were 17,000 children whose hearing was defective, and some 30,000 suffering from diseases of the middle ear; these figures did not include children who had not begun to attend school or had left, nor the diseases of the nose and throat, which contributed to produce deafness, and adults were omitted altogether. The new hospital was provided with every appliance necessary for correct and early diagnosis, which was the first step, but investigations would also be carried out with a view to prevention, so that the hospital, like other hospitals, would try to find ways of making its curative functions superfluous. This ideal might never be reached, but it was by research that it would be most possible to add to the happiness and efficiency of the people by preventing deafness. The voluntary hospital system had been passing through what had been perhaps the most critical period of its existence, and it was extraordinarily gratifying to find that latent and unsuspected sources of help had been revealed. It was significant that within two days there had been opened in London two voluntary institutions—the Ferens Institute of Oto-Laryngology at the Middlesex Hospital (see page 296) and this Royal Ear Hospital. Voluntary effort had shown that it could rise to the height of its responsibilities and provide all those extensions which had been the glory of the voluntary system in this country. The vice-chairman of University College Hospital proposed a vote of thanks to Mr. G. Duveen, which was received with acclamation. On the motion of Dr. A. M. H. Gray, Dean of the Medical School of University College Hospital, a cordial vote of thanks was adopted to Mr. Chamberlain, who afterwards made an inspection of the new buildings.

MANCHESTER ROYAL INFIRMARY.

Plans for the erection of the new nurses' home in connexion with the Manchester Royal Infirmary are well advanced; the site in York Place has been partly cleared, and it is hoped that sufficient money will be received to justify the commencement of building operations within the next few months. In the annual report of the Infirmary for the year ending December 31st, 1926, it is stated that £12,750 was collected during the twelve months, making the total so far received £58,401, of which £7,188 was raised by the nursing staff. The existing facilities for nurses are to be increased shortly by the addition of an extra floor over the present dining hall, thus doubling the seating accommodation. Since there are at present about 1,500 patients on the waiting list, the erection of more wards is urgently necessary, but the additional nursing staff of 379 required cannot be housed until the new home is available. There has been a further increase in the number of cases treated at the Royal Infirmary and its central branch, the number during 1926 being 27,677, as compared with 26,347 in 1925, and 24,255 in 1924. The daily average of new casualty cases is now 75.82, whereas in 1920 it was only 50. The combined income of the Infirmary and the Barnes Convalescent Home at Cheadle has risen from £89,532 in 1925 to £93,163 in 1926, but the total ordinary expenditure in the two years has increased from £118,828 to £121,365 in the last twelve months. The total number of patients treated in both institutions rose from 57,499 in 1925 to 59,232 in 1926, and 9,567 operations were performed.

BRADFORD HOSPITAL FUND.

In spite of the severe trade depression the "record" sum of £12,293 was contributed during 1926 by the mills and workshops of Bradford to the local Hospital and Convalescent Fund. At the annual meeting of the Fund the chairman, Mr. Herbert Gill, described how these contributions had grown from small beginnings. The employees were now contributing more than double the amount they gave in 1918. During the last three years, notwithstanding the prevalence of bad trade and unemployment, the Fund had endowed the various hospitals of the city with over £20,000 annually. During the twenty-two years of the Fund's existence Bradford workers had given £142,360, and since the Fund started £362,979 had been raised by systematic subscriptions. With the return of a reasonable amount of employment, the chairman believed that the present subscription total could be doubled. Since the establishment of "Scholars' Day" twenty-one years ago the school children of the city had contributed over £3,000 to the Fund, and a competition organized in connexion with the Bradford Cricket League had yielded over £2,500. The various entertainments organized by the Fund in 1926 had produced about £5,000, and since the institution of the Peel Park gala in 1864 it had been instrumental in contributing £65,300. The Lord Mayor stated that there were 120,000 subscribers to the Fund among the workpeople of the city. A sum of £10,451 was presented to the Royal Infirmary, which contains 265 beds, of which some 220 are occupied daily. There was still an adverse balance of £6,328, but the confident hope was expressed that the necessary money would be received in a very short time.

COMPLIMENTARY DINNER TO DR. LILY BAKER.

On Friday, February 4th, a complimentary dinner to Dr. Lily Baker, B.A., M.B., B.Ch.Dubl., F.R.C.S.I., was held at Fortt's Restaurant, Clifton, Bristol, to celebrate her appointment to the honorary staff of the Bristol Royal Infirmary in charge of the ante-natal department. Miss Frances G. Robinson presided, and about one hundred guests were present. The guests at the high table included Lady Barrett, C.B.E., M.D., M.S., Professor Winifred Cullis, O.B.E., D.Sc., Miss Letitia Fairfield, C.B.E., M.D., D.P.H. (barrister-at-law), Sir Ewen J. Maclean, M.D., M.Ch., F.R.C.P., F.R.S.E., Professor D. C. Rayner, O.B.E., F.R.C.S., Professor J. A. Nixon, C.M.G., M.D., F.R.C.P., Dr. R. S. Statham, O.B.E., M.B., Ch.M., and Mr. C. F. Walters, F.R.C.S. The remaining guests were seated at three long tables, and the gathering presented a gay and brilliant scene. Lady Barrett, M.D., M.S., who proposed the toast of the guest of the evening, congratulated Dr. Baker on her success, which had been won through the value of her work. The ante-natal work in a hospital staffed by men, put into the hands of a woman, was a great compliment. She looked forward to the time when Dr. Baker would be occupying a still higher position than that on which they were congratulating her. Professor Winifred Cullis said that Dr. Baker's appointment was an open proof of the capacity of women and the generosity of men. She was helping to break down the feeling that there were things which men could do and which women could not. Dr. Letitia Fairfield referred in a witty speech to Dr. Baker's work in the W.R.A.F. during the great war, when she displayed remarkable skill and discrimination. "Her specialty then was the management of colonels, who were hard to please," said Dr. Fairfield. "For one thing," she added, "in the R.A.F. colonels were not long past their twenty-first birthday, and they regarded women appointed to the force as one of the minor horrors of war." In reply, Dr. Baker expressed her appreciation of the honour conferred upon her, and said she was proud to belong to such an old, honoured, and famous institution as the Bristol Royal Infirmary. Her appointment was another honour to the women graduates of the ancient University of Dublin. Sir Ewen J. Maclean proposed "The Bristol Royal Infirmary." He congratulated the infirmary on the action that function was celebrating, and spoke of the past, present, and future position of the institution. Dr. J. A. Nixon, in his reply, said that Dr. Baker had carried on the work of the gynaecological and obstetric departments at the infirmary during the war, and for the last three years had been responsible for the work of the ante-natal clinic. She had thereby made herself indispensable—hence her appointment to her present position. Sir Ewen Maclean proposed the health of the chairman, Miss Robinson, who responded briefly.

Correspondence.

CHANGES IN THE CLINICAL ASPECTS OF DISEASE.

SIR,—In the very interesting presidential address of Sir Humphry Rolleston to the Medical Society of London, reported in your issue of January 15th, the apparent great increase in the incidence of appendicitis since it began to be treated surgically is discussed. Now, whilst I am not prepared to maintain by statistics that appendicitis was as common before the introduction of its present name in 1886 (it was only a year or two later when it began to be treated generally by the surgeons), I have always thought that the present generation of surgeons have on insufficient grounds concluded that the disease began to increase in incidence soon after the introduction of the name "appendicitis." Those of us who can remember the time when there was no such name well know that they were accustomed to call what they now know to have been appendicitis by other names, according to the clinical symptoms and the subsequent course of the disease. Inflammation accompanied by pain, etc., in the right iliac fossa was diagnosed as typhlitis and perityphlitis, and anyone who wishes to know the state of medical knowledge on this subject will find these conditions described in any of the textbooks published between 1870 and 1886. In *Quain's Dictionary of Medicine* (1882) under "Perityphlitis" (Aetiology) occurs the following passage:

> "The most frequent cause of this *not uncommon* affection is an extension of inflammation from the caecum or the vermiform appendix, more especially if the typhlitis . . . has proceeded to ulceration." (The italics are mine.)

Probably some cases of typhoid, intestinal obstruction, adenitis, abscesses, indigestions, and peritonitis were what we now know as appendicitis, and although the termination of many of those cases may have shown peritonitis, one must not look under this heading alone for all the fatal cases of appendicitis.

It is perhaps difficult for the present generation of surgeons to picture the course of cases of appendicitis when they were not operated on and when it was not recognized that the appendix was so prone to inflammation.

The course and termination of non-surgically treated cases of appendicitis would—and did—vary very much. By far the greater number of cases of typhlitis after a short illness got better. In some abscesses were formed; these were diagnosed as perityphlitis. Usually such abscesses, if localized, opened into the bowel, and after a more or less prolonged illness the patient got gradually better. Some opened into the peritoneum, and the patient either died of peritonitis or the abscess opened secondarily into the bowel. Some, after a prolonged illness, opened through the abdominal wall or were incised or aspirated by the surgeon.

Typhoid in those days was fairly common and was often treated in the ordinary medical wards and in the patients' own homes; it was before the days of the Widal reaction. Perityphlitis was recognized as one of the sequelae of typhoid. It may be that some of the cases were really appendicitis. Abscesses in the abdomen, phlegmons, etc., occurred sometimes and may not all have been due to glandular and other abscesses, but appendicular in origin.

A very large number of the milder cases I have no doubt were diagnosed as one of the varieties of indigestion, dyspepsia, flatulence, etc., just as such cases are at the present day. Looking back on my student days and when a resident in Edinburgh Royal Infirmary in 1886, and comparing my experience now with then, I am doubtful whether I saw fewer cases then of what I know now were appendicitis than I do at the present day.

I remember well the teaching of my chief, the late Professor John Wyllie, for cases of inflammation in the right iliac fossa. He advised opium and belladonna in frequent doses. The patients had pain, often vomiting, usually constipation, sometimes intestinal obstruction. In two or three days there was an evacuation in a large number of cases and the patient gradually got better, sometimes with evidence of pus in the stools, which we used to look out for; in some peritonitis ensued and they died. His teaching was that the opium kept the abdomen quiet and relieved the pain; the belladonna, I have no doubt, acted later as an evacuant.

I write about those days from memory and to emphasize the fact that appendicitis was well recognized at that time under a different name. Why the appendix was late in being recognized as forming so commonly the primary seat of the disease when the cases came to the *post-mortem* room is partly explained by the facts that the appendix is a very small organ, that it would often be destroyed by the disease and would often be in the middle of a purulent abscess, and in the progress of the disease other complications may have arisen, such as septicaemia, pyaemia, abscesses in other parts of the body, septic pleurisies, pneumonias, etc. To find the deaths from what would now be registered as appendicitis it would be necessary to look for some of them under the above headings as well as under peritonitis, ileus, intestinal obstruction, phlegmons, gastritis, and persistent vomiting—these showing the further progress of a disease beginning as appendicitis.

As an historical study it would be interesting to investigate the bearing that the introduction of a new name for an old disease, or of new methods of diagnosis or treatment, has had on the apparent incidence of such disease.—I am, etc.,

Leith, Jan. 16th. WILLIAM ELDER, M.D., F.R.C.P.E.

SPENGLER'S BACTERIOLOGICAL THEORY OF CANCER.

SIR,—Dr. J. Barcroft Anderson's interesting communication on Dr. Carl Spengler's researches on cancer, published in your issue of January 8th (p. 79), opens up many points of great importance to research workers on cancer.

Spengler's investigations show that he has succeeded in obtaining cultures of a bacillus from human carcinomata, and that this organism, unlike other known micro-organisms, causes extremely active proliferation of certain human cells, especially the blood platelets of an elderly person—for example, a person of optimum cancer age.

If these results are confirmed they promise to be of great scientific and practical value in the solution of the cancer problem. Therefore it seems urgently necessary that Spengler's researches should be repeated and investigated by other research workers.

If Gye's most promising virus theory and also Spengler's bacteriological theory of cancer are correct, then further researches will show the relation between the two theories.

As Spengler's carcinoma bacillus is pleomorphic, and as it can exist in a minute granule form, microphotographs of which I have seen, it is possible that Gye's virus may be a filter-passing form of a carcinoma (or sarcoma) bacillus such as Spengler's, and that this filter-passing form may be of such low virulence that it needs some substance—for example, Gye's "specific factor"—in order to enable it to produce a tumour when inoculated into a suitable animal. In this connexion it is interesting to remember that the tubercle bacillus can exist in a very minute granule form of low virulence; Spengler[1] and, subsequently, Much[2] have made statements to this effect.

With regard to Spengler's observation that when a loopful of blood from an elderly person was mixed and incubated with a pure culture of his carcinoma bacillus active proliferation of the blood platelets was produced, and that some of the blood platelets became nucleated, it will be remembered that Bedson[3] of the Lister Institute has also observed nucleated blood platelets in mammalian blood.

In order to assist those investigators who may wish to repeat Spengler's researches, I have been in communication with Dr. Spengler, who has kindly given me full details of the method used by him for these researches. He especially points out that extremely great care must be taken to prevent the contamination of the cultures by organisms other than the carcinoma bacillus. In addition to the strictest aseptic precautions employed in obtaining the

[2] Much: *Beitr. z. Klin. d. Tuberk.*, 1907, Bd. 8, Heft 1.
[3] Bedson: *Journ. Path. and Bact.*, 1921, vol. xxiv, p. 469.

carcinomatous material for inoculating the tubes of culture media, before inoculating the tubes he *surface* sterilizes the tumour particles by his well known method,[4] which, at the Koch Institute, he elaborated for the cultivation of tubercle bacilli. Briefly, this method is as follows:

1. The tumour particles are first washed for one to two minutes in 1 : 1,000 corrosive sublimate in water.
2. The particles are then *thoroughly* washed in a series of *sterile* clock glasses containing sterile broth.
3. The tumour particles are carefully transferred with a sterile inoculating needle (loop) to tubes of sterilized culture media. The formulae of Spengler's liquid media are given in your issue of January 8th (p. 79); the formulae of the solid media are the same except for the addition of 20 grams of agar to each. In making streak cultures on the solid media the tumour particles must first be broken down to expose the interior of the particles. This is done by rubbing them with the sterile needle against the inside wall of the culture tube. The particles are then streaked over the surface of the culture medium. Similarly the particles must be broken down in inoculating tubes of liquid culture media. The inoculated tubes should be capped with sterile, perforated india-rubber caps, and incubated at 37° C. Usually many sub-cultures must be made from each primary culture in order to obtain pure cultures of the micro-organism in the form of a bacillus, and the greatest care must be taken to prevent contamination. Spengler advises that his culture media, both with and without the addition of 1/2 per cent. glucose, should be used in investigating each tumour.

It may be mentioned that a series of researches is contemplated in order to investigate the immunity of various types of normal people and cancer cases against Spengler's carcinoma bacillus. These investigations will be carried out by means of a modification of the precipitinometer method devised by me for the measurement of tuberculosis immunity, and described in a paper[5] read before the Section of Bacteriology and Immunity at the Seventeenth International Congress of Medicine, 1913. For these researches an antigen prepared from Spengler's carcinoma bacillus will be used instead of the tuberculo-antigens employed for investigating tuberculosis immunity.—I am, etc.,

WALTER H. FEARIS,
Late Bacteriologist to the City of Cardiff and County of Glamorgan Public Health Laboratory.

Brightlingsea, Jan. 25th.

MIGRAINE AND ACETONURIA.

SIR,—The letters that have been published and many private letters received from medical men asking for the name of the capillary tubes for reliable bedside test for acetone mentioned in my memorandum (BRITISH MEDICAL JOURNAL, December 18th, 1926, p. 1176) encourages me to submit some further observations on this interesting problem of the metabolic storm associated with ketone bodies in the urine and hypoglycaemia.

In my letter published on January 31st, 1925 (p. 240) under the heading "Acidosis and acetonaemia in relation to sea-sickness," this test was described as follows:

> A simple test for acetone can easily be performed at the bedside by using a small endolytic (capillary) tube containing sodium nitro-prusside and ammonium chloride (put up by Fletcher and Fletcher, of Holloway, N.). One large drop of urine is placed on a sheet of notepaper and saturated with a common washing soda crystal the size of a pea. This saturated urine is allowed to run up the tube by capillary attraction, the reagent having been shaken to the lower end; if acetone is present in the urine in quantity a petunia colour develops in about thirty seconds, and even when only small amounts are present a rosy or amethyst flush is noticeable in a minute or two. When acetone is absent the powder dissolves with nothing more than a pale straw coloration, which does not develop further. The same firm also supplies capillary tubes for bedside test for diacetic acid, sugar, and albumin.

The paradox of glucose relieving a condition brought on by excessive intake of sugar, as pointed out by Dr. Allison, puzzled me when I first observed it in the routine examination of flying officers for the airship section of the navy, during the first two years of the war. Acidosis was regarded as of considerable importance; it was always suspected and the urine tested for acetone if the applicant was unable to hold his breath comfortably for more than thirty seconds. This simple test proved to be almost infallible. Should the officer or rating have had previous experience in flying, a history of air-sickness was present in all cases of positive acidosis. By "air-sickness" a condition identical with sea-sickness is inferred, due to the motion of the airship, seaplane, or kite balloon, and not in any way due to high altitudes; this point made clear the fact that air-sickness was always worse in kite balloons, working at a lower altitude, than in any other form of aircraft. During two years with the R.N.A.S. the close relation between air-sickness and acidosis appeared to me to be an established fact.

The resumption of civil practice, with its opportunities for keeping cases of cyclic vomiting in children (usually associated with endocrinic unbalance and calcium deficiency) under continuous observation, made clear the explanation of this apparent paradox. Excessive sugar, especially chocolates, produced an acid stool and positive test for acetone, but without at first any symptoms. The latter could be prevented and the acetone cleared up by administration of glucose and a purge or rectal wash-out. If, however, these non-toxic acetone bodies remained untreated, the intake of fats, or excitement alone, appeared to precipitate a metabolic crisis, with attendant ketosis and hypoglycaemia—evidenced by a distressing attack of vomiting, car or train sickness. It is certain that when this crisis occurs the hydrogen ion in + + + proportion, whipped up by an ungrateful and unkind metabolism, takes command and makes matters very unpleasant for the patient.

These are some of the pieces in this metabolic jig-saw puzzle as I see them. A complete picture requires the erudition, great biochemical experience and intimate knowledge of the H-ion of an authority like Mr. J. E. R. McDonagh, whose wonderful work on the nature of disease appears to be little read and less understood by the majority of the members of our profession.

In conclusion, I cannot allow one sentence of Dr. Cammidge's kind and helpful letter of January 1st to pass unchallenged when he says: "The heredity factor cannot of course be treated." Already in West Sussex promising pre-natal work has commenced by the administration of sodium calcium lactate, alkalis, and endocrine therapy to expectant mothers who give a history of acidosis or faulty calcium retention as evidenced by bad teeth, or who have already borne children who have presented these symptoms. The babies of this pre-natal work are subsequently put on similar prophylactic treatment soon after birth.—I am, etc.,

MARMADUKE FAWKES, O.B.E., M.B., B.S.Lond.

Midhurst, Sussex, Jan. 26th.

SMALL-POX AND VACCINATION.

Sir,—Dr. Killick Millard is very well known as the energetic and able medical officer of health for Leicester, a very progressive and well equipped town. What he says will be quoted far and wide. I have read the correspondence in the last three numbers of the BRITISH MEDICAL JOURNAL. I gather that Dr. Millard means that we might safely drop the compulsory vaccination of infants, but that we should try to induce adults to submit themselves and their older children to vaccination, and to repeat the process every few years. It seems clear that Dr. Millard thinks that vaccination has great value at the proper time and place. Does he mean that the State should cease to interfere in the matter and that vaccination should be left to the patient and the doctor in every case?—I am, etc.,

GEORGE JONES, M.B., D.P.H.,
Lecturer on Public Health, London Hospital Medical College.

February 5th.

SIR,—In reply to Professor F. E. Wynne's letter in your issue of February 5th:

1. He suggests that Dr. Barry's report on the Sheffield small-pox epidemic of 1887-88 is "one of the strongest arguments in favour of vaccination ever published." I think it all depends upon how one looks at it. I readily grant that the attack rate and case mortality as found by Dr. Barry showed a marked difference in favour of those persons who had been vaccinated. This merely confirms—what has, of course, been conclusively proved over and over again—that vaccination confers temporary protection upon the individual. It affords no real proof whatever that vaccination protects the community. (If anyone

[4] C. Spengler: *Zentralbl. f. Bakt. u. Parasit.*, 1901, Bd. xxx; *Zeit. f. exper. Path. u. Ther.*, 1909, Bd vi.
[5] Fearis: *Proceedings*, Seventeenth International Congr. Med., London, 1913, Section iv, Part ii, pp. 149-159.

doubts this let him imagine that Dr. Barry had been investigating the effect of small-pox inoculation—if such had continued in vogue—instead of vaccination. He would have obtained figures equally or even more striking, showing the advantage of the inoculated over the uninoculated; yet this would have been no proof that inoculation was protecting the community. Indeed, it might well have been the case that inoculation was doing much more harm than good!) On the other hand, I submit that the fact that such a widespread and fatal epidemic (total, 6,023 cases with 563 deaths—see page 196 of report) could occur in a city like Sheffield, in which infant vaccination had been so thoroughly enforced that, according to Dr. Barry, no less than 97.9 per cent. of the population had been vaccinated, is surely proof of the unreliability of such vaccination to protect the community.

2. Professor Wynne makes a very interesting statement that the present outbreak of small-pox in Sheffield is "certainly reverting from the very mild type with which we have recently been familiar to a form quite indistinguishable from 'old-fashioned' small-pox." Are we to understand from this that Professor Wynne really believes that the strain is definitely changing? He does not tell us how many cases have proved fatal so far. Merely that some of the cases have a grave and disfiguring eruption is hardly sufficient to prove a change in strain. Some cases have always been more severe than others, and even in chicken-pox there may be a "grave and disfiguring" eruption.

3. Professor Wynne states that modern measures of fighting small-pox have been fully carried out in Sheffield and have now failed. Surely it is a little early for him to abandon hope. His letter is dated January 26th, yet I note from the Registrar-General's returns for the last three weeks for which the figures have been published, that the new cases of small-pox in Sheffield have been as follows: Week ending January 15th, 157 cases; January 22nd, 66 cases; January 29th, 54 cases.

4. Professor Wynne next refers to those who have a "passion" for antivaccination. I hold no brief for the antivaccinists. I regret their inability to believe what I believe as much as they regret, I imagine, my inability to believe what they believe. Professor Wynne says that they cannot be convinced or converted "by reason or by any amount of facts or statistics." He may be right as regards the statistics, but then, unfortunately, the statistics are not all on one side. As regards reason, I am still optimistic enough to hope that truth, which is stronger than either reason or statistics, will ultimately prevail. As regards "passion," however, antivaccinists are not the only people affected with this malady. What about those people who openly express the wish that the present non-fatal small-pox would "cause a few more deaths"? Apparently they think it is better to burn now than to be guilty of heresy and burn hereafter, as the Holy Inquisition used to teach!

5. Lastly, Professor Wynne says that as regards policy he and I are "quite in accord." I am sorry that I cannot entirely endorse this suggestion, much as I should like to be in agreement with such an old and valued friend. I quite admit that in certain circumstances (which I hope may never occur)—*for example, if a really* fatal strain of variola major were to invade Leicester and really threatened to get out of control—I should not hesitate to urge vaccination and revaccination of the entire community, but I should hesitate seriously before I attempted to inflict vaccinia wholesale upon 200,000 people just because a few hundred had contracted such a comparatively trifling and non-fatal affection as variola minor. Regarding vaccination as at the best a necessary evil, to be used as little as possible rather than as much as possible, I would much prefer to confine it to protecting those living in actually invaded houses, where, naturally, its utility is greatest.

As regards Sheffield, however, Professor Wynne is, of course, far better able to judge than I am, and if he thinks that the situation in Sheffield is such as to call for universal vaccination and revaccination it is for him, not for me, to decide.—I am, etc.,

Health Offices, Leicester, Feb. 6th. C. KILLICK MILLARD.

AN OCCUPATIONAL SWELLING.

SIR,—The condition described by Mr. Ogilvie (February 5th, p. 232) as seen in a violinist is well known. It is represented in the Museum of the Royal College of Surgeons by a plaster cast (Gen. Path. No. 2.2), which was placed there in 1912, to illustrate hypertrophy due to repeated pressure. In this, and analogous cases, there is probably some increased thickening of the epidermis. The cast was made from a man 24 years of age who had been in the habit of playing six hours daily since he was 8 years old.—I am, etc.,

CECIL F. BEADLES,
Pathological Curator, Royal College of Surgeons of England.

London, W.C.2, Feb. 7th.

WIRELESS CALLS FOR MEDICAL HELP AT SEA.

SIR,—The question of medical help at sea by wireless is occasionally mentioned in the press, but in actual practice it has not at the present time the value it ought to and might have. The following messages and notes of a case I recently had to deal with may be of interest. I was serving on a West African intermediate steamer, and the case was on a large cargo boat about 280 miles away in the tropics.

Message No. 1. (Filed 12.20 p.m.)

Doctor S.S.——.

Commenced on the 21st instant with strong perspiration, when patient was given 5 grains quinine; three days later perspiration slighter. Yesterday temperature in the morning was 97.5°, with pulse 68; in the evening temperature 98°, pulse 70. This morning, temperature normal; pulse 73; patient weak; please prescribe.—Captain S.S. ——.

Reply to Message No. 1. (Filed 1.30 p.m.)

S.S. ——.

Age, rating; how long out; ailment within fourteen days previously; extra heat exposure on the 19th or 20th; any venereal; bowels; any wine difficulty, sickness, or indigestion; tongue, teeth; please reply.—Surgeon S.S. ——.

Message No. 2. (Filed 2.20 p.m.)

Doctor S.S. ——.

Captain's age, 58 years; 26 days out; no ailment previous to the 21st; only subject to constipation and stomach trouble, also excessive weakness; tongue fairly clear, teeth good; temperature now normal, pulse 74; condition probably due to heat. —Captain.

Reply to Message No. 2. (Filed 3.30 p.m.)

S.S. ——.

Medicine No. 6 in Medical Guide with addition of tincture nux vomica 50 minims, also tincture of digitalis 50 minims, if in medicine chest, or tincture of calumba 50 minims; take two tablespoonfuls four times a day for two or three days, then drop to three times a day after meals. Moderate dose of Epsom salts well diluted, repeated each morning if necessary, stimulate very moderate whisky and plenty of soda; food light and moderate, no made-up dishes or entrees; rest lying down as much as possible.—Surgeon S.S. ——.

Was a diagnosis possible from message No. 1? Did it give much of a clue to any line of treatment? The case might have been one of a cadet not acclimatized to tropical heat and moisture; an old sailor with bad teeth or none, who had flatulent dyspepsia; the master or a senior officer who, after a spell of extra anxiety, had been exposed to extra high temperature with almost complete saturation. The latter proved to be the case, and the diagnosis was heat collapse.

If medical relief by wireless is to be of any real value it will have to be carefully considered and codified, remembering that those for whom it can be of most value and who most need it are those least able to help themselves owing to conditions beyond their control, who are most independent and self-reliant, and most necessary members of our race—the sailors in cargo and tramp steamers, without whose labours those at home could not live.

I am told by experienced wireless operators that there is no difficulty in arranging a simple code (which ought to be international). The flag under which a ship sails is not a trustworthy guide as to the nationality and language of those on board. In order that a diagnosis may be made certain essential information should be sent with the first message in regard to age, rating, temperature, pulse, bowels, etc., followed by the particular symptoms of the case. The medical officer receiving the message must

only prescribe medicines on the Board of Trade list; this list should be simplified and made more practical. The medical officer who receives a message must forget his own equipment, and think of what can be done where there is no orderly and no hospital, where, as in the tropics, cold drinking water is over 80°, and where no ice or cold baths are available for sunstroke

Another argument in favour of codification is that the want of it leads to waste of time. In the case related the interval between the sending of the first message to the receipt of the last was over three hours, and atmospherics were propitious; but atmospherics are common in the tropics, and codification would have made two messages unnecessary and the advice could have been sent earlier.—I am, etc.,

Brighouse, Feb. 2nd. F. F. BOND, M.D.

COLEY'S TREATMENT.

SIR,—I read with great interest in your issue of January 29th (p. 211) the courteous letter from Dr. Coley. I was under the impression that the treatment associated with his name has always been carried out in this country by injection into the tumour itself. This was the reason for omitting it from my recent report in which I was dealing with systemic treatment.—I am, etc.,

London, N.W.3, Feb. 7th. R. G. CANTI.

A MEMORABLE OBSTETRIC TRAGEDY.

SIR,—In "Nova et Vetera," under the heading "A memorable obstetric tragedy" (February 5th, p. 255), it is stated that Sir Richard Croft had no medical degree or diploma. This is not correct. He was M.D. Marischal College, Aberdeen, 1792, and according to the Marischal College records was a Member of the Corporation of Surgeons. He was son-in-law to Dr. Denman the obstetrician.—I am, etc.,

Sheffield, Feb. 5th. R. W. INNES SMITH.

SUFFOCATIVE CATARRH.

SIR,—I recently attended a child of 4 years (now convalescent) for bronchopneumonia following severe whooping-cough. An infant (12 months) and a child (5 years) lived and slept in the same room. Both presented symptoms of the disease two days after its onset in the first case. The infant died in forty-eight hours from most virulent bronchopneumonia or capillary bronchitis; prominent features were early and marked dyspnoea, indrawal of the alae nasi, cyanosis of the lips and finger-nails, and coarse adventitious respiratory sounds accompanying both respiratory phases. The child 5 years old lived for one week and showed a similar clinical picture with no signs of consolidation or bronchial breathing. The course in both cases was practically apyrexial, and the body seemed incapable of any protective reaction, general or specific. Both fatal cases terminated in convulsions. I consider that diminution in the respiratory lung area, with deficient blood aeration and excess of CO_2 leading to convulsions, was the direct cause of death. "Suffocative catarrh" admirably describes both cases. Should not bronchopneumonia, a highly contagious disease, be therefore a notifiable disease? In congested industrial districts such as mine proper means of isolation and general hygiene would, I am certain, greatly reduce the mortality of this appalling disease.

A haemolytic type of streptococcus is very constantly present in bronchopneumonia, and may be associated with the pneumococcus and Friedlander's bacillus. It is probably the main source of the disease. Antistreptococcus serum is antimicrobic: has it any practical application in treatment? Active immunity can be produced in animals by streptococcal injections: could this fact be utilized in the treatment of contacts? There is much labour, much money expended in researches for the cure of cancer and tuberculosis, and nothing towards solving the pathology and treatment of bronchopneumonia. A staff of properly remunerated bacteriologists should reside in the areas of general practice and carry out first-hand intensive studies of the microscopy and bacteriology of bronchopneumonia. They should study the reactions, whether focal or general, in animals injected with cultures from the different micro-organisms present in each case, and note the virulence of the reaction or reactions. That which produces the severest reaction, general or local, may be the root cause.—I am, etc.

M. F. MCELLIGOTT, M.B.N.U.I.

Lodge, near Wrexham, Dec. 22nd, 1926.

THROMBO-ANGIITIS OBLITERANS.

SIR,—Since the paper on thrombo-angiitis obliterans (recording two Irish cases) published in your last issue (p. 225) was written, my attention has been called to an article by Telford and Stopford (*Medical Annual*, 1926, and BRITISH MEDICAL JOURNAL, 1924, ii, 1035) recording four British cases, and also to a reference in the *Journal of the American Medical Association*, January 1st, 1927 (p. 61) which reads as follows:

"*Thrombo-Angiitis Obliterans in Non-Jew.*—Beer's patient was an Irish-American, aged 42. Not only the lower extremities but also the upper extremities were affected. The case had previously been diagnosed as Raynaud's disease because the patient was not a Jew. No light is thrown on the etiology of the disease by this case."

—I am, etc.,

Dublin. W. I. DE C. WHEELER.

THE NURSING PROFESSION.

SIR,—My attention has been called to the leading article entitled "The nursing profession," in your issue of February 5th (p. 248), in the course of which you state that the College of Nursing now "controls the leading nursing journal, the *Nursing Times*, and through this official organ is able to exclude many undesirable advertisements—a most effective mode of bringing wisdom to the ignorant."

This statement is not only so inaccurate, but makes by implication so serious a charge against the *Nursing Mirror*, that I am compelled to ask you to give equal publicity to the following letter.

By common consent the *Nursing Mirror* is "the leading nursing journal," and has held that position since it was founded in 1888. I have before me, as I write, a certificate signed by Messrs. T. Turketine and Co., chartered accountants, that its weekly net sales for the three months ended December 31st, 1926, averaged 43,092 copies. It would be interesting to see a similar net sales certificate for the *Nursing Times*.

I do not know by what interpretation the writer of the article can justify his use of the word "leading." I am content to leave that matter to the judgement of your readers, and of the nursing profession, who have given the most practical proof in their power of the estimation in which they hold the *Nursing Mirror*. But I will add this: that the most powerful single factor which led to the establishment of the College of Nursing itself was the influence continually exerted in its favour by the *Nursing Mirror*. And I will add further that the identification of the College with another weekly paper has not affected either the status or the circulation of the *Nursing Mirror* in the slightest degree.

The writer of the article adds that the College, through its organ, "is able to exclude many undesirable advertisements." No reader of this assertion could fail to draw the conclusion that undesirable advertisements are *not* excluded by other nursing journals—of which, of course, the *Nursing Mirror* is the chief. You will permit me to say that the strictest supervision is exercised over the advertisements printed in the *Nursing Mirror*, and to express, on behalf of the proprietors of that paper, my astonishment that such an imputation should have been made in the columns of the BRITISH MEDICAL JOURNAL.—I am, etc.,

GEOFFREY C. FABER,
Chairman of Faber and Gwyer, Ltd., Proprietors of the *Nursing Mirror*.

London, W.C.1, Feb. 8th.

*** The question which is the leading of two or more journals is a matter of opinion; but Mr. Faber is at fault in supposing that our reference to censorship of advertisements was meant to convey a reflection upon the conduct of any other nursing periodical.

Obituary.

JOHN HEDLEY, M.D.,

Past President, North of England Branch, British Medical Association.

THE death of Dr. John Hedley of Middlesbrough removes a veteran medical practitioner of outstanding character who was greatly respected by his colleagues and held for many years a prominent place in the public life of his district. He died suddenly on February 4th while on a visit to London.

John Hedley was born on January 5th, 1843, the youngest son of William Hedley of Ovingham, Northumberland. His father died when he was 12, and at 15 he was apprenticed to Dr. Aitchison of Wallsend, taking at the same time his medical course at Newcastle, where he became house-surgeon after obtaining the M.R.C.S. and L.S.A. diplomas in 1864. He began practice at Middlesbrough in 1866 when the town was in its infancy, and saw it grow to its present size. During the Franco-Prussian war of 1870-71 he served with the Red Cross, and from the outskirts of Strasbourg saw the white flag of surrender. He returned to Middlesbrough in 1887, and took the M.D. of Durham University, relearning his Latin for the purpose at the age of 44. He was appointed surgeon to the North Riding Infirmary, and built up a very large practice in Middlesbrough and around it; acquiring a leading position professionally and in the social life of the district. He acted in various semi-official capacities as medical referee, chiefly on the owners' side, in cases connected with compensation under the various Employers' Liability Acts, and his decisions were hardly ever contested by the workmen's side, for he was universally trusted by the workers as well as the employers. He was certifying factory surgeon for the district, and only relinquished that post in his eighty-second year, after fracturing his pelvis in October, 1924. He retired from practice in July, 1914, but resumed it in the following November, working practically throughout the war, in the absence of his successor on active service.

Dr. Hedley married in 1873, and with his wife started in 1887 a nursing service for the workmen employed by her family; they took the chief part in developing this later into the Middlesbrough and District Nursing Association, which now acts for the whole town. He had an unusual power of absorbing fresh ideas and applying them to practice, and retained this until the end of his long life; on the night before his sudden death he was discussing new medical knowledge with the greatest interest and intelligence. He had, moreover, a most remarkable clinical and therapeutic instinct, and in his younger days was medically very much ahead of his time in such matters as fresh-air treatment and surgical cleanliness. In the late eighties he assisted in the Home Office investigation of the Middlesbrough pneumonia epidemics, and wrote an article about this in Sir Thomas Oliver's book on *Industrial Diseases*. Another characteristic was his gift for making a friend of a casual acquaintance, and the vivid interest he took in everyone and everything he encountered.

In local public affairs Dr. Hedley played a distinguished part. He was elected to the Middlesbrough Town Council in 1886, and became mayor in 1902 and later alderman, holding the latter office until 1925. He was a J.P. for the borough and county, and a member of the Tees Conservancy Commission for many years. He was appointed by the Lord Chancellor chairman of the committee for recommending magistrates for the county borough of Middlesbrough; and he was a member of the Insurance Committee and the Education Committee. To celebrate their golden wedding in 1923 he founded and endowed a scholarship at Middlesbrough High School, and on that occasion Dr. and Mrs. Hedley were presented by the local medical profession with a beautiful piece of gold plate. His wife predeceased him by almost two years, and he is survived by eight children; two sons and two sons-in-law are medical men. Dr. Hedley had been a member of the British Medical Association for a large part of his active professional life and continued in membership after his retirement, and he had held office as President of the North of England Branch.

ROBERT WILLIAM FELKIN, M.D., F.R.S.ED.,

Late Lecturer on Tropical Diseases and Climatology, Edinburgh.

WE regret to record the death, on December 28th, 1926, of Dr. Robert William Felkin, at Havelock North, New Zealand, after an adventurous life as explorer, missionary, lecturer, and physician.

He was born in 1853 at Beeston, Notts, and received his early education at Wolverhampton Grammar School. While a child he met David Livingstone, and his imagination was fired by the tales he heard about Africa. As he grew older the call of that continent became more insistent, and a meeting in London, in 1877, with Mackay of Uganda decided his career. Abandoning a commercial position, he entered as a medical student at Edinburgh, but before he had proceeded far he was sent by the Church Missionary Society to Uganda, which he reached by way of Egypt, travelling up the Nile from Cairo. At Khartoum he first met Gordon, and further on Emin Pasha, whose knowledge of natives and local conditions was later to prove so helpful to the band of missionaries. The journey from the Nile to the Great Lakes was fraught with danger and hardship, but eventually Felkin and his companions reached Uganda. In February, 1879, he was presented to King M'tesa, whose personal physician he then became. Soon afterwards an anti-missionary movement commenced, and Felkin and his party went in great danger of their lives. His pluck and ready wit did not desert him, and he issued a warning to the king that should any harm come to the missionaries a great disaster would befall the tribes. As a sign that this should be so he foretold that the sun should be darkened; the eclipse duly occurred at the expected time, and Felkin was established as a great "medicine man." Much of his time in Uganda was spent in the study of local diseases, and he also made anthropological measurements of the pygmies. He left Uganda with the envoys of King M'tesa to Queen Victoria, and returned with them safely to the Nile, thus destroying an old superstition that no white man could journey to the Great Lakes and back without losing his life. His next expedition was to Zanzibar, where he lived for three years and worked with the explorers Schweinfurth, Buschta, Junker, and Sir Harry Johnston. His interest in the welfare of the natives made him a strong opponent of the slave trade, and he became a very active member of the Anti-Slavery Society.

He then returned to Great Britain, and in 1884 obtained the diplomas L.R.C.P., L.R.C.S.Ed., after which he pursued his medical studies at Heidelberg and Marburg, receiving the M.D. degree of the latter university in 1885. His observations in Uganda had given him much knowledge of the then little known tropical diseases, and in 1886, at Minto House, Edinburgh, he delivered his first lecture in that subject. For the next ten years he held the post of lecturer in tropical diseases to the Edinburgh Medical School, and carried on private practice in the city. During this time he took up the study of psychotherapy, translating Hilger's work and writing a book on hypnotism. His health had been weakened by the hardships he had endured in Africa and by malaria; he was therefore compelled to leave Edinburgh in 1896, and to take a long rest, after which he began specialist work in nervous diseases and gynaecology in London, at the same time being consulting physician to various companies with tropical interests. His publications include the *Geographical Distribution of Tropical Disease* and an article on the climate of the Egyptian Soudan. He was joint author of *Uganda and the Egyptian Soudan*, published in 1882. Dr. Felkin was in Germany when the late war broke out, but was able to return after six weeks, when he served for a time with the National Guard. In 1916 his health again gave rise to anxiety, and, with his wife and daughter, he sought the more congenial climate of New Zealand, which he had previously visited in 1912. There for ten years he carried on medical practice in spite of periodical attacks of ill health. His strong personality and clinical acumen quickly established him as a consulting physician, especially in border-line cases and in mental abnormalities of children. His kind and generous nature attracted patients from both islands, and also from Australia. He was a prominent Freemason, and an active supporter of the British Medical Association. He is survived by a wife and daughter in New Zealand, and by two sons.

The Services.

MEDICAL ARRANGEMENTS FOR THE SHANGHAI DEFENCE FORCE.

THE following are the medical arrangements which have been made for the troops composing the Shanghai Defence Force:

Colonel H. Ensor, C.B., C.M.G., D.S.O., Deputy Director of Medical Services of the Western Command, has been appointed A.D.M.S., with Major D. G. Cheyne, *M.C.*, R.A.M.C., from the Royal Army Medical College, as D.A.D.H. Lieut.-Colonel S. Boylan Smith, D.S.O., O.B.E., R.A.M.C., Senior Medical Officer at Hong-Kong, will act as temporary D.A.D.M.S.

Colonel Ensor will have under his administration a general hospital of 600 beds, a field ambulance, and a field hygiene section, all of which have left England. Brevet Colonel E. Ryan, C.M.G., D.S.O., R.A.M.C., is in command of the general hospital, Lieut.-Colonel S. L. Pallant, D.S.O., R.A.M.C., of the field ambulance, and Captain G. O. F Alley, *M.C.*, D.P.H., R.A.M.C., of the hygiene section. An advance party of seventeen members of Queen Alexandra's Imperial Military Nursing Service have left England for duty with the general hospital. An advanced depot of medical stores will shortly be dispatched from England.

The troops from India will be accompanied by a field ambulance, a general hospital, and half a sanitary section.

A hospital ship is to be fitted up at Hong-Kong with a staff from England under Lieut.-Colonel D. Ahern, D.S O., R.A.M.C., including fourteen members of Queen Alexandra's Imperial Military Nursing Service.

Each artillery brigade and infantry battalion is accompanied by a medical officer.

The following medical officers of the Royal Navy have been sent to China:

Royal Marine Battalion: Surgeon Commander C. E. Greeson and Surgeon Lieutenant H. H. Fisher.

H.M. Hospital Ship "Maine": Surgeon Captain W. W. Keir, Surgeon Commanders F. J. Gowans, H. R. B. Hull, F. J. D. Twigg, H. B. Padwick.

H.M.S. "RENOWN."

THE following medical officers of the Royal Navy are serving in H.M.S. *Renown* during the voyage of their Royal Highnesses the Duke and Duchess of York:

Surgeon Commander G. R. McCowen, O.B.E.; Surgeon Commander H. E. Y. White, M.V.O., O.B.E. (appointed on staff of Duke of York, January 1st, 1927); Surgeon Lieutenant J. M. Sloane.

TERRITORIAL ARMY MEDICAL OFFICERS' ASSOCIATION.

LIEUT.-COLONEL L. A. HARWOOD, R.A.M.C.(T.A.), honorary secretary of the Territorial Army Medical Officers' Association, writes: Will you allow me to remind medical officers of the Territorial Army, both active and retired, that the annual dinner of this association will be held on Thursday, February 24th, at 7.30 for 8 p.m., in the Café Royal, 68, Regent Street, W.1. The council, for the future prosperity of the association, is very anxious to make this dinner a great success. I would take this opportunity of drawing the attention of medical officers to the advantages of joining this association. It has been formed to provide an organization for the consideration of all matters that in any way are of interest and benefit to the Territorial medical officer. Dinner tickets (12s. 6d., without wine) can be obtained from me at 37, Russell Square, London, W.C.1.

TERRITORIAL DECORATION.

THE Territorial Decoration has been conferred upon the following officers of the R.A.M.C., T.A., under the terms of the Warrant of October 13th, 1920: Major John L. Hamilton, M.C., Major Arnold Morris, Captain Greville B. Tait.

DEATHS IN THE SERVICES.

LIEUT.-COLONEL JAMES CORT MARSDEN, Madras Medical Service (ret.), died on October 28th, 1926, aged 71. He was born at Bangalore, and was the son of Edmund Marsden of Ootacamund; he was educated at the Madras Medical College and at University College, London. He took the M.R.C.S. and L.S.A. in 1879, and entered the I.M.S. as surgeon on October 31st, 1879, *became lieutenant-colonel* after twenty years' service, and retired in 1910. Most of his service was spent in civil employment in the Madras Presidency.

Surgeon Captain Seton Guthrie Hamilton, 1st Life Guards (ret.), died in Edinburgh on January 1st, aged 72. He was born in that city on March 3rd, 1854, was educated at St. George's Hospital, and took the M.R.C.S. and L.R.C.P.Ed. in 1879. After filling the post of house-physician at Westminster Hospital, he entered the army as surgeon in 1881, and was posted to the 1st Life Guards. He retired with a gratuity in 1894. He served in the Egyptian campaign of 1882, and received the medal and the Khedive's bronze star.

Surgeon Frederic Morell Mackenzie, Bengal Medical Service (ret.), died in London, after a long illness, on January 30th, aged 83. He was the son of Mr. Frederic Mackenzie of Tiverton; he received his education at the London Hospital, and took the M.R.C.S. in 1866, and the L.S.A. in 1868. He entered the I.M.S. as assistant surgeon in 1868, became surgeon in 1873, and retired on account of ill health in 1877. He was afterwards for many years in practice in London.

Universities and Colleges.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

LICENCES have been granted to the following forty-six candidates who have passed the necessary examinations and conformed to the by-laws and regulations:

Gertrude Alphonso, R. Andrews, N. Attygalle, R. Bandyopadhyay, H. B. Bramer, Augusta J. Blumenthal, H. J. Burrows, R. W. Butler, Mildred Carpenter, A. Carr, B. Chaudhuri, Pamela M. G. Chute, F. H. N. Cruchley, A. S. El-Katib, V. Freeman, J. H. Gubbin, V. Hall, E. O. Harris, J. W. O. Holmes, S. G. Irlam, Freda C. Kay, A. E. Kingston, J. S. Lewis, E. M. Lourie, R. W. L. May, H. E. Mayfield, J. L. Newman, F. G. Parker, Muriel V. Paton, G. Pether, R. K. Pillay, E. N. Price, L. J. Rae, B. H. Rattray, E. Rees, W. Rosenberg, R. Rutherford, M. Schwartz, Helen D. Scott, S. Segal, M. Shaw, E. S. Vergette, D. P. Watting, L. A. Wiles, Marian E. Williams, R. M. Williams.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

A QUARTERLY meeting of the Royal College of Physicians of Edinburgh was held on February 1st, when Dr. G. M. Robertson, president, was in the chair.

Dr. James Richan Drever and Dr. Alan Leonard Smith Tod, *M.C.*, were introduced and took their seats as Fellows of the College, and Dr. William Bell was elected a Fellow.

The following were elected Members: R. F. Aitken, Thiagarajah, A. M. Affleck, J. K. Slater, and P. N. Kapur.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

Postponement of Poor Law Bill to Autumn Session.

PARLIAMENT was opened by the King in State on February 1. The Government proposes that the session should be a short one, and that a new session, to extend over 1928, shall be held this autumn. To that session the Cabinet has decided to postpone several important measures which had been proposed as part of this year's programme, but which are put back owing to doubts about their being generally accepted or because the preoccupation of the Government with industrial troubles in the autumn prevented full consideration of technical or administrative questions which the projected bills would involve. Among the bills thus postponed are the Factories Bill and the Poor Law Reform Bill. Bills proposed by the King's Speech for the consideration of Parliament before August include one to amend the King's title, one defining and amending the law relating to industrial disputes, one altering the law relating to leasehold premises, and one dealing with the law of unemployment insurance. Proposals are to be put forward for reorganizing certain of the Government departments in Scotland. It is understood that boards will thereby be changed to departments but the change is purely administrative.

Until the week before the session commenced the general expectation had been that the Poor Law Bill would have a prominent place in the King's Speech and in the work of the session, but the Government appears to have been influenced by the criticisms or indifference with which many public authorities have received Mr. Chamberlain's proposals. The association of Poor Law reform with the suggestion of *institution* a block vote for public health services seems to have prejudiced the case for the bill. There has been strong opposition to the Factories Bill by industrialists, who contend that the present time is unsuitable for the introduction of stricter factory standards involving reconstruction and expenditure. Objection has also been taken to the proposal to treat many workshops as factories.

Speaking in the House of Commons, on February 8th, during the debate on the Address, Mr. Baldwin briefly defended the restriction of the Government programme. He said that it was intended to close the session at the end of July and give the House a substantial rest through the late summer and early autumn, and to begin a new session in the early part or middle of November. He *felt that the House had* been suffering from work which had been too long and too continuous. From the point of view of efficacy of their work a less strenuous session in the early part of this year was a matter of very great importance. The question of Poor Law reform was so large and comprehensive that it would be impossible to take it this session unless a long autumn session was contemplated. He hoped *it might be* possible, when the new session started in November, to get ahead with this important piece of work. The same thing was true of the Factories Bill

Medical News.

A LISTER centenary celebration will take place at King's College Hospital Medical School, London, on Monday, April 4th, at 8.15 p.m., when Sir Watson Cheyne, Bt., and others will speak of their experiences as house-surgeons and dressers under Lord Lister. All old King's College Hospital students are invited to attend.

THE Confédération Internationale des Etudiants has founded a scientific cinematograph commission consisting of representatives from student organizations in all countries for the purpose of obtaining information on this subject and for preparing an international catalogue of scientific films. The National Union of Students of England and Wales has organized an exhibition of scientific films at its third annual congress to be held at Bristol this year from March 24th to April 1st. There will be a special exhibition of medical films. Particulars can be obtained from the Congress Secretary, National Union of Students, 3, Endsleigh Street, W.C.1.

DR. W. W. KEEN of Philadelphia celebrated his 90th birthday on January 19th, when he received numerous congratulatory messages from his fellow countrymen and from friends abroad. The celebrations were centred in the First Baptist Church, where an address was presented by the President of the Brown University, Dr. Keen's alma mater, and Dr. Keen himself responded by summarizing the advance which has taken place in surgery and medicine during his long and active career.

IN the article on certification of the fact of death published last week (p. 252) certain views were attributed to the Registrar-General which were really those of the Home Secretary. The error occurs in the last two paragraphs, where proof of the fact of death is under consideration. It was to the Home Secretary that should have been attributed the opinion, first, that the coroner may ask the doctor why he has not seen the body, and, secondly, that for such a service the coroner (if the schedule made by the local authority enables payment to be made for such services) may, on sufficient occasion, ask another practitioner to see the body and report.

THE treasurer of the Royal Medical Benevolent Fund gratefully acknowledges the sum of £30 from Dr. (Phil.) Otto Rank of Vienna, through Dr. Marie Moralt.

AT the meeting of the Post-Graduate Hostel at the Imperial Hotel, Russell Square, W.C., on February 17th, at 9 p.m., Mr. G. S. Stebbing will discuss fractures of the upper third of the femur. On the following evening Mr. Ernest Clarke will speak on ophthalmic emergencies. Dinner (5s.) will be served at 8 p.m. All medical practitioners are welcome.

THE Fellowship of Medicine announces that Dr. Wilfred Harris will lecture on trigeminal neuralgia, at 5 p.m., on February 17th, at the Medical Society, 11, Chandos Street, W.1. On February 14th, at 2 p.m., Mr. H. Kisch will give a demonstration at the Central London Throat, Nose and Ear Hospital. On February 18th, at 5 p.m., Mr. Viner will give a demonstration on ocular palsies, at the Royal Westminster Hospital. The lecture and these demonstrations are open to members of the medical profession without fee. The following courses are in progress this month: at the Lock Hospital, in venereal diseases; at the Paddington Green and Victoria Hospital, in children's diseases; at St. John's Hospital, in dermatology; and at the National Hospital, Queen Square, in neurology. The special courses in March will include diseases of the chest at the Brompton Hospital, diseases of children at the Queen's Hospital, ophthalmology at the Royal Eye Hospital, gynaecology at the Chelsea Hospital, orthopaedics at the Royal National Orthopaedic Hospital, and a practitioners' course at the London Temperance Hospital, late afternoons. Syllabuses of these special courses and the general course-programme are obtainable from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

THE Royal Society of Medicine announces in our advertisement pages that work to be submitted for the second award of the Nichols prize must reach the Secretary of the Society, 1, Wimpole Street, London, W.1, by October 1st. Under the terms of the will of the late Dr. Robert Thomas Nichols the prize of £250 is offered every three years for the most valuable contribution towards "The discovery of the causes and the prevention of death in childbirth from septicaemia"; it is open to any British subject.

PROFESSOR KARL HERZFELD of Munich has been nominated professor of physics at Johns Hopkins University, and Professor Leonor Michaelis of Berlin director of the new pathological institute in the same university.

ON the occasion of a recent visit to Buenos Aires Professors Sergent of Paris and Pittaluga of Madrid were elected members of the Argentine Medical Association.

THE Home Secretary has appointed Dr. Gerald Roche Lynch, O.B.E., lecturer in chemical pathology at St. Mary's Hospital and on forensic medicine at the Westminster Hospital, to be senior official analyst to the Home Office in succession to the late Mr. John Webster. Dr. Lynch has been junior official analyst to the Home Office since 1920.

THE annual dinner of the Cambridge Graduates' Medical Club will be held at the Langham Hotel on Tuesday, March 1st, at 7.30 p.m., with Sir Humphry Rolleston, president, in the chair. All Cambridge medical men who are graduates of the University are eligible for membership. Application forms can be obtained from the honorary secretaries, Mr. R. M. Vick of 113, Harley Street, W., and Dr. F. G. Chandler of 1, Park Square West, Portland Place, N.W.1.

THE Dean of the Birmingham Dental Hospital asks us to state that the Council and Senate of the University of Birmingham on February 2nd granted permission to Licentiates in Dental Surgery to wear a black stuff gown with coloured cord (dark red) on facings and across the top of shoulder with forearm of sleeve gathered up with the same cord and black button. This gown may be obtained from Messrs. Ede and Ravenscroft, 93 and 94, Chancery Lane, London, W.C.2, the official gown makers to the University.

A CONVALESCENT home for the sick children of Birkenhead and Wirral is to be provided by the conversion of a house presented to the Birkenhead and Wirral Children's Hospital by Mr. F. Kroyer Kielberg, who has also offered to contribute financially towards the cost of the reconstruction and of the maintenance of the home for the next ten years. The value of the house is estimated at over £12,000, and the cost of equipping between £3,000 and £4,000; the yearly upkeep is expected to be about £2,500.

THE January issue of the *Cripples' Journal* contains a full report of the joint conference on the care of crippled and invalid children, which was held by the Invalid Children's Aid Association and the Central Committee for the Care of Cripples, at the London House of the British Medical Association last November.

THE French Government, which recently gave notice that it would re-establish its requirement of a visa for foreigners entering France, announces that the requirement will not apply to ordinary British travellers.

THE second volume of the *Transactions of the Sixth Biennial Congress of the Far Eastern Association of Tropical Medicine*, held at Tokyo in 1925, has now been received. It contains 110 papers, principally relating to bacteriology, parasitology, and public health.

THE Carnegie Foundation has presented Professor Witmaak with the sum of 3,000 dollars for his researches on oto-sclerosis.

DR. BERNHARD SPATZ, editor of the *Münchener medizinische Wochenschrift* since 1886, celebrated his seventieth birthday recently.

THE number of medical practitioners in Germany is 44,715 for a population of 63 million—that is, a proportion of one practitioner for every 1,400 inhabitants. The specialists are classified as follows: Dermatologists and urologists, 2,428, or 5.4 per cent.; physicians, 1,688, or 3.7 per cent.; neurologists and psychiatrists, 1,661, or 3.7 per cent.; surgeons, 1,536, or 3.4 per cent.; obstetricians, 1,479, or 3.3 per cent.; oto-rhino-laryngologists, 1,338, or 3 per cent.; ophthalmologists, 1,185, or 2.6 per cent.; pediatrists, 975, or 2.2 per cent.; gynaecologists, 570, or 1.3 per cent.; phthisiologists, 409, or 0.85 per cent.; orthopaedists, 312, or 0.7 per cent.; gastropathologists, 239, or 0.5 per cent.

A SPRING tour in Morocco has been organized by the *Bruxelles-Médical* for doctors and their families at reduced prices, leaving Bordeaux on April 10th; visits will be paid to Casablanca, Marrakech, Rabat, Meknès, Fez, Oudjda, and Oran. Three cruises in the Eastern Mediterranean will also be organized, leaving Marseilles on March 11th, 29th, and April 21st. Further information may be obtained from the Section des Voyages de Bruxelles-Médical, 29, Boulevard Adolphe Max, Brussels.

DR. ETIENNE BURNET, assistant director of the Institut Pasteur at Tunis, and Dr. Chaumier of Tours, well known for his vaccine lymph, have been elected national correspondents of the Académie de Médecine.

UNDER the direction of Professor Jeanselme a post-graduate course in dermatology will be held at the Hôpital St.-Louis, Paris, from April 25th to May 21st, and a course in venereology from May 23rd to June 17th. A course in the therapeutics of dermatology and venereology will be held from June 20th to July 12th, and instruction in laboratory technique will be arranged in connexion with these courses. Further information may be obtained from Dr. Burnier, at the Hôpital St.-Louis.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the BRITISH MEDICAL JOURNAL must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the JOURNAL, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the BRITISH MEDICAL JOURNAL are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscera Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

QUERIES AND ANSWERS.

RECURRENT TONSILLITIS.

"SCRUTATOR" asks for suggestions for treatment of a girl, aged 17 years, who annually suffers from a violent attack of pustular tonsillitis. The tonsils were removed in childhood, and a second operation carried out two years ago. At this time, also septic teeth were cleared from the mouth. Can recurrence be prevented?

EPIPHORA.

"G. A." (Norfolk) wishes to hear of a remedy for the treatment of epiphora occurring without obvious cause. *In his case there is* no trouble, no obstruction to outflow, or obvious gland trouble, or error appears normal except the incr excitation, such as change of temperature, or exposure.

INCOME TAX.

"WEST AFRICAN MEDICAL STAFF" inquires what tax would be payable on pension and emoluments amounting to £1,270.

*** *At the present rate of tax, and assuming that he is entitled* to earned income relief, the amount of tax would be £162 2s. If he is married that sum would be reduced by £18, and, of course, other allowances might be due—children, life assurance, etc. Earned income is defined in Section 14, Income Tax Act, 1918, to include "any pension superannuation, or other allowance, deferred pay or compensation for loss of office given in respect of the past services of the individual . . . in any office or employment of profit." *Prima facie* this would seem to cover our correspondent's case.

"X. Y.," a whole-time county medical officer of health, who would not have a car but for professional purposes, replaced a second-hand car by a new one of similar make—cost of replacement (as distinct from improvement), say £100. What allowance can he claim?

*** The statute gives an allowance in such circumstances only in respect of expenses incurred wholly exclusively and necessarily in the performance of the duties of the office. The inquirer does not state what allowance, *if any*, he receives from the county for the use of a car; if he receives such an allowance it will be a little difficult to satisfy the local income tax authorities that it is insufficient to cover all car expenses. If he does not, he might press a claim to a proportion of the renewal cost calculated according to the ratio of "county" to "personal" use over the life of the displaced car.

LETTERS, NOTES, ETC.

THE HISTORY OF DIPHTHERIA.

FLEET SURGEON W. E. HOME writes: Dr. E. W. Goodall's interesting letter in the JOURNAL of January 29th (p. 216) explains to me at last the great puzzle of "croup," which harassed one so much, as he says, forty or more years ago, and I blush to think it may have been inflicted on us by Francis Home. I suppose there was some good in his book on croup (1765), for it was translated into French, and published in Paris forty years later in 1810 (*Dict. Nat. Biography*), though I cannot say if it sold. The further one examines the nearer one gets to Dr. J. D. Rolleston's view that diphtheria was not truly differentiated in the eighteenth century. Osler says Aretaeus described it; that was many centuries earlier.

VACCINATION AND SMALL-POX.

"D.P.H." writes to express the view that the public will never get vaccinated so long as vaccination is performed by the vaccination officer. Every medical man is competent to vaccinate—an operation any student can perform. "D.P.H." suggests that every practitioner should vaccinate in his own practice and receive a fee of, say, 3s. 6d., which is only half the usual fee. In this way, he thinks, nearly 100 per cent. of the population would be vaccinated.

HERPES ZOSTER AND VARICELLA.

DR. J. M. LOFTUS (Brockley) reports the case of a woman, aged 22, who spent the Christmas holidays in the country. While there a doctor was called to attend her mother, aged 56, for herpes. The younger woman began to suffer from chicken-pox on January 14th, the typical vesicles appearing on the following day.

THE VOLUNTARY HOSPITAL AND ITS FUTURE.

"BRIGHTON" writes: I have read with interest Mr. Hogarth's article (SUPPLEMENT, February 5th, p. 37) on the future of the voluntary hospital. In his suggestion for opening the doors of hospitals to the middle classes he appears to have overlooked the item of fees to the surgeon or physician in charge. He mentions the paying wards of the Brighton Hospital; they are there, but the doctors are not allowed to accept any fees, because the man who founded and endowed the wards expressly forbade this in his will. Also the Sussex Provident Scheme, which supplies everything to all and sundry, does so at the expense of men who get no fees.

INTESTINAL DISINFECTION.

DR. L. WHEELER (London, W.) writes with reference to disinfectants given by the mouth to suggest that the subject is of such vital importance as to warrant a special research inquiry into the *in vitro* and *in vivo* action of some of the known antiseptics and bactericides. The results of such a research undertaken by the Ministry of Health or the British Medical Association would be welcomed as valuable illumination on the practicability, or impossibility, of affecting the faecal flora by disinfectants given by the mouth. It should be possible with rats, rabbits, etc., to obtain direct information as to the changes occurring in the intestinal flora with definite doses of different antiseptics introduced into various lengths of gut and contrasted with controls to which the trial preparation has been given by the mouth.

"THE MICROTOMIST'S VADEMECUM."

PROFESSOR J. BRONTË GATENBY (Zoological Department, Trinity College, Dublin) writes: It is proposed to bring out shortly a new edition of Lee's *Microtomist's Vademecum*. The eighth edition was published in 1921, and there is now a call for a new edition, which will include recent advances. The ninth edition which I am editing in conjunction with Dr. E. V. Cowdry of the Rockefeller Institute, N.Y., will, in addition to general technique contain articles by the following specialists: Dr. Da Fano "Neurological technique"; Dr. Helen Pixell-Goodrich, "Protozoa"; Dr. W. R. G. Atkins, "Histological applications of measurements of acidity and alkalinity, and of oxidation and reduction"; Dr. Robert Chambers, "Microurgy" (that is, micro dissection, etc.); Dr. Payling Wright and Dr. Rogers Brambell "Cultivation of tissues *in vitro*"; Dr. W. Cramer, "Fats"; Mr. Thornton Carter, "Bone and teeth," and various *sections* by Dr. Reginald Ludford and myself on cytological technique. The purpose of this letter is to invite research workers and others to forward to me, as soon as possible, any new information they may have. I may mention that *it is not proposed* to include bacteriological technique in the forthcoming edition.

A MANCHESTER DISCLAIMER.

THE *Manchester Guardian* appears to be in the habit of publishing under its list of deaths advertisements from families desiring to express thanks for sympathy shown to them in a bereavement. One of these, dated February 8th, contains an expression of the family's thanks to Dr. Grant Davie for his unremitting care of the patient. Dr. Grant Davie asks us to state that he had no knowledge of or connexion with the announcement. We have seen such tributes in American and some other foreign and overseas newspapers, but we agree with Dr. Davie that the practice is to be condemned.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges and of vacant resident and other appointments at hospitals, will be found at pages 43, 44, 45, 48, and 49 of our advertisement columns, and advertisements as to partnerships, assistantships and locumtenencies at pages 46 and 47.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page *51*.

The Hunterian Oration

ON

HUNTER'S IDEAL AND LISTER'S PRACTICE.

DELIVERED BEFORE THE ROYAL COLLEGE OF SURGEONS OF ENGLAND ON FEBRUARY 14TH, 1927,

BY

SIR BERKELEY MOYNIHAN, BT.,
PRESIDENT.

ON this day, the 199th anniversary of his birth, we commemorate the services of John Hunter to the science and the art of surgery. In this year we celebrate the centenary of the birth of Lister. Hunter and Lister. From all who have ever served the cause of surgery these two stand apart by reason of the immeasurable gifts which they have conferred upon their fellow-men. May we to-day recall something of Hunter's work and of his ideals in respect of the conquest of disease, which the genius of Lister made possible!

Man's life is warfare. The individual, the whole race, is beset by foes—unresting, relentless. Against them our defence, if we are ever to subdue them, must be carefully planned, and diligently strengthened. But defence, however stubborn, is not enough. Attacks designed after scientific study of the enemy strongholds and methods, and launched with impassioned zeal, must never for one instant falter. Not all our attacks meet with success. We are cheered when we gain some notable victory, yet when we suffer defeat, as wave after wave of our advance is checked and repulsed, we do not lose heart. Failure inspires us to fresh and still more eager endeavour.

In this year, the centenary of Lister, we rejoice to acclaim the greatest victory ever won by man against his enemies. We who are in active work to-day are perhaps unable to measure the full extent of that victory; for during the long fight, lasting almost exactly sixty years, our standards have been so changed that we cannot truthfully compare our work with that of our intellectual ancestors. Operations from time immemorial so mortal as to be prohibitive are now freely performed without anxiety. Operations formerly unimaginable are now matters of everyday occurrence. The mere tale of such work done does not adequately illustrate the change. On my last day as surgeon on the full staff of my hospital I performed six abdominal operations. Not one of these was practised by any member of our staff during the year in which I became house-surgeon, nor had such a diagnosis as was made in three of these cases, and verified at the time of operation, ever then been attempted in the history of medicine. Above all, a statement of facts and a comparison of methods does not in adequate degree convey to our minds the difference of outlook, of the intellectual and spiritual approach of a man to his daily task, as between the surgeon in the days before Lister and since. It is barely possible for us to imagine how men felt about their daily work when an eminent surgeon could speak of his hospital as a "house of death"; when hospitals "were little short of pest-houses," as Lister said;[1] and when the oppressive mortality compelled the closure of wards or of a whole hospital for months, until the curse was lifted from them.

The change, of incalculable benefit to humanity, is due to one man—Lister.[2] Before Lister's time the surgeon dreaded the almost inevitable consequences of his operation. Lister made surgery so free from risk that we now may say that, with due care in the detailed application of the lessons learnt from him, it is no longer the fatality of the operation itself which is feared. In these days, when a patient dies it is not because the operation leads to septic complications which he cannot withstand. We fear for him chiefly, if not only, when the extent of the operation is formidable, or when the most sensitive regions of the body, sometimes remote and almost inaccessible, are attacked by methods which half a century ago were beyond the wildest dreams of the most adventurous mind. Our main concern in these days is with the condition of the patient before and after operation. We seek to make him as safe for surgery as surgery has been made safe for him. Lister, in short, has made all the methods applied by the surgeon almost devoid of risk in themselves. The risks run are dependent upon accessory factors—upon the state of the patient, the nature and extent of the disease, the intrinsic susceptibility of organs, or the anatomical conditions responsible for the difficulties which must be surmounted.

Do we fully realize the implication of all these statements? We are at the end of an epoch, indisputably the greatest in our history—*the epoch in which manipulations* by the surgeon have been robbed of the prohibitive dangers which formerly repelled. Now when failure comes it is the individual who fails, not the methods of which Lister laid the eternal and unshakable foundations. Lister by his genius recruited an army of surgeons which has gained astounding victories. The human body from crown to toe has for all time become our indisputable kingdom, within which we may come and go at pleasure, undismayed by the pestilences which menaced us before Lister forever subjugated our enemies. Lister is indeed Captain of the men of Life.

We who inherit the glorious legacy of Lister must not be content merely to enjoy and exploit our incomparable heritage. No great teacher measures his success in contemplation of his own efforts. His greatness lies rather in *the work which he inspires others to do—in the tradition* not of past accomplishment but of future devotion. Traditions are fostered and increased not by routine observance of ancient ceremony, nor by mute obedience to outworn creed, but by active faith forever seeking new truths and exploring new paths, in conformity with the old spirit and with unchanging devotion to the great ideal of which the tradition is the shrine. There is immortality of the tomb, and immortality of the resurrection. The soul of a great teacher is born again in his pupils. What, then, are we to do with Lister's gift to mankind? We use it already to the immense advantage of the individual sufferer; a therapeutic weapon of unapproached perfection, we are making it, and we must continue, in increasing degree, to make it far more than that. After the great war the statesmen of Europe, moved by the highest ideals, sought, not perhaps wholly in vain, to convert the allied victory into lasting peace. The statesman's ideal is a warless world. War is to end war. Ideals are not so much for capture as for pursuit, and though the statesman may never attain his ideal, yet the happiness and progress of mankind surely depend upon the grim and perhaps endless struggle to reach it. So, too, for us surgery must be regarded as the most powerful weapon of research upon man and animals ever given to our hands; and the end of research is not the cure only, but, far better, the prevention, of disease.

HUNTER'S IDEAL.

The Oration I have now the honour to deliver was founded 114 years ago as "a lasting mark of respect to the late John Hunter."[3] Let us turn to Hunter, the greatest surgeon of all the ages before Lister, and see how he regarded the art he practised. In the opening lecture of each surgical course Hunter said to his students:[4]

> "The last part of surgery, namely operations, is a reflection on the healing art; it is a tacit acknowledgement of the insufficiency of surgery. It is like an armed savage who attempts to get that by force which a civilized man would get by stratagem."

In his *Treatise on the Venereal Disease*,[5] a work more frequently quoted for its glaring errors than for its profound truths, he indicates one of the ways which lead to this ideal, the prevention rather than the cure of disease. He writes:

> "As disease in general should not only be cured, but when it is possible prevented, it will not be improper to show, as far as we know, how that may be done: for in this disease we can with more certainty *prevent infection*, its origin being known." He

then adds, "... corrosive sublimate in water, about a grain or two to eight ounces, has been known to prevent the catching of the disease."

Hunter anticipated that a time would come when surgery, gaining much from the general advance of knowledge, might be rendered both knifeless and bloodless. I do not speak with irony when I say that Lister's work has brought us appreciably nearer to Hunter's ideal. It is true that its first effect has been to increase a hundredfold the operations practised, and to cause an advance into territories never before subdued. The advance was timorous, halting, and at first so unsafe that the men who led the thought of the day, whose stubbornness was iniquity, whose changeless idolatry was the worship of the images of their fathers, did not hesitate to demand that he who practised such a deadly operation as ovariotomy should be indicted for manslaughter. Lister so taught us that to-day, with little risk and with incomparable advantage to our patients, we, strong in the faith that our fathers rejected, not only attack disease with remedial operations, we also seek out and expose, we inspect and study it in its deepest recesses, and in its earliest structural manifestations, sometimes discovering its cause, or at least its impressive antecedent, and often tracing the lines of its gradual extension. We are at last coming to appreciate the reaction of living organs upon each other. As I have claimed on earlier occasions, we have created and are slowly building up knowledge from which our predecessors were completely debarred—not new science, but new vision of an old science: the pathology of the living. This branch of surgical learning will continue to grow, and therein surely lies our hope that surgery may one day help to end surgery, by enabling us to discover how those earliest processes of disease may be inhibited. Some claim this as the era of preventive medicine. Is there not preventive surgery also? Hunter was possessed of an ideal. Lister gave the power to realize it. We too wage war to end war. "*Pereant arma bellica.*"

At the end of a long, arduous, and triumphant surgical campaign we, if we are prudent and foresighted, shall survey our equipment and our arsenals and consider the strategy of our next advance. The military leader of to-day seeks help from every branch of science; the victorious leader is he who best knows where to seek the help of which he is in need; who has the genius early and quickly to perceive how all new knowledge can be best applied to the art of war. Surgery too is warfare; its advance is conditioned by contemporary progress in every branch of science, and its virtue lies in the number and the vigour of its allies. Into what alliances, then, has surgery entered with other branches of knowledge?

SURGERY AND THE ANCILLARY SCIENCES.

The science of physics has brought radiology to our aid, and the discovery of the x ray has rendered the living body translucent. After an opaque meal these rays disclose the normal movements of the alimentary canal, and we learn, as in no other way, the functional anatomy of the intestine. Any defect of outline may reveal a structural deformity and perhaps enable us to make a precocious diagnosis of conditions whose terminal stages when neglected are fatal.

The art of the chemist can be allied with that of the physicist, as the work of Graham of St. Louis has shown, with the result that the physiology of the liver, the functional anatomy and the pathological conditions of the gall bladder, the association of gall-bladder activity with movements of the duodenum, may all be studied by a new method. And this method, in alliance with that of the surgeon, realizes another stage in our advance towards the prevention of gall stones, themselves a tardy result of insidious changes originating elsewhere. Chemistry lends its invaluable aid in discovering for us the functional activity of the kidneys, and by its investigation into the cholesterin and calcium content of the blood is helping us to understand some of the problems relating to the functional activity of the liver and gall bladder. Such conditions as acidosis and alkalosis offer impenetrable secrets if chemistry is not brought to our aid.

Physiology by its inclusion in the Faculty of Medicine acquires a double function: it remains a pure science, directing its inquiries solely to the advance and perfection of knowledge; but it becomes also an applied science, in league with clinical medicine and surgery. As he sees his conquest of knowledge applied practically to the saving of human life the physiologist will be encouraged to yet closer study of normal and aberrant vital processes in man. He too should stand with the surgeon by the bedside. The great gap between the powers of the surgeon and the aid which the physiologist might give would thereby be reduced, and the reproach removed from his science that in this sense it is lagging far behind. The surgeon's activities enable him to uncover the hidden mysteries of early structural changes. He offers new opportunities for the study of normal and perverted function to the physiologist, with whom he might inquire into those early functional changes which correspond to and are caused by organic disorder. The surgeon seeks earnestly to know what degree of impairment of function is to be attributed to the textural changes which our new methods have revealed to us. The physiologist may tell us much that we are eager to learn of the effects of our manipulations upon the normal activity of tissues, and of the full or imperfect return of function when diseased tissues have been removed. With his help we may learn what without him we may never learn—the significance and the methods of the causation of early symptoms, and the origins of those pathological changes with whose late mutilations we are, unhappily, only too familiar. With our help he has learnt what otherwise he could not learn—that, for example, the spleen by an excessive destruction of red cells may be responsible for a condition of jaundice, and that the removal of the enlarged spleen results in the disappearance of the jaundice, which is thereby demonstrated to be of haemolytic origin. Physiologist and surgeon are, far more often than is realized, necessary to each other, and a closer communion should exist between them. Many of the truths the physiologist endeavours to teach can be demonstrated more clearly in the wards than in the laboratory, and are therefore, because of this human interest, impressed almost indelibly upon the minds of students. The phenomena of cerebral compression, of Traube-Hering curves, of Cheyne-Stokes respiration; the symptoms of hyperthyroidism, and those produced when the secretion of the thyroid gland is diminished or absent; many of the aspects of jaundice, in addition to the demonstration of haemolysis as its occasional cause, and of the relations between the liver, the spleen, and the bone-marrow; illustrations of the normal and aberrant functions of the kidney; changes in the chemistry and constitution of the blood, may all profitably be discussed in the ward rather than in the laboratory or the lecture theatre. Students would then realize from their earliest days the truth which later comes almost with a shock—that physiology and anatomy are not fundamental subjects, but are interstitial, and should grow alongside and be incorporated with the facts of clinical medicine and surgery, which they illuminate and explain.

Interstitial tissue has as one of its functions the carrying of blood vessels to nourish cells whose activity is dependent upon the richness of their blood supply. Biology provides the interstitial tissue of surgery; the activity and the growth of surgery depend upon the nourishment which biology may bring. Unless surgery calls in the aid of all the sciences with which biology is related it will remain as static as ancient geometry, whose figures were drawn once for all. Modern geometry is concerned with function, with the variations of movement by which a figure is described. Surgery's concern in the future will not only be with the states produced—with established organic disease—but with its allies it will help to eradicate some of those variations in function by which perhaps they have been caused, with which they are associated, and by which their presence is declared.

If sometimes we blame Sharpey and his school for the unhappy cleavage between anatomy and physiology we must at least acknowledge the great debt we owe to him for laying so firm the foundation of new methods for the

studying of functional anatomy in man and in animals. Physiology, with its offspring biochemistry, has introduced physical and physico-chemical methods—methods of quantitative observation which have supplemented where they have not supplanted the merely qualitative methods. The brilliant work of Sherrington, Lucas, and others upon the nervous system gave us fresh conceptions of it; further advances along their lines were becoming difficult until the application of thermionic valves made it possible, by recording the transmission of impulses in the afferent nerves, to investigate the effects of stimuli upon the sensory end-organs. And in the interpretation of symptoms, a study to which my old friend James Mackenzie bent the strength of a most eager and original mind, physiology alone can read the occult significance. In acute pancreatitis there is, as Halsted,[1] a great benefactor of mankind, first told us, a lividity of the face. Why? Is it due to some disordered action of the respiratory system imposed by the closeness of the affected organ to the diaphragm and the structures which lie above it, or is there circulatory stasis, or alteration in the blood pigment? Physiology is the master of all the methods by which these three possible causes may be quantitatively investigated. Estimations of the oxygen saturation of the arterial blood give information of disturbance of respiratory function—information which we may compare to that derived from a measurement of the amount of blood urea when the renal functions are deficient. Estimations of the carbon dioxide combining power of the blood are essential if we are to recognize the presence and the degree of acidosis. Circulatory stasis may be gauged by the ethyl iodide method of measuring the circulation rate. Alterations of the blood pigment are detected by the spectroscope, and quantitative estimations of abnormal pigments are readily made after the method of Hartridge.

Like the physiologist, the bacteriologist is engaged in work which is ranged alongside our own. The more he discovers of the offensive powers of bacteria and of the defensive mechanism of living flesh under their attack the nearer are we brought to our surgical ideal. The alliance between bacteriologist and surgeon has been necessary for the proof that the true estimate of an antiseptic is not measured only by its bactericidal value tested in the laboratory, but also by its power to encourage the blood serum or the tissues themselves to ward off and to break up an attack. Hunter, with the crude methods which were all he had at his disposal, demonstrated the tryptic power of wound discharges, and anticipated a part of the admirable work of Almroth Wright during the war. Who could have imagined, when Lister's work began, that to-day we should be able to keep tissues alive in our laboratories, breeding them and growing them in captivity, separating the one kind from the other, noting the influence which one type of cell is able to produce on its neighbours, and thus coming by the kind of knowledge which John Hunter so earnestly sought—a knowledge of the intrinsic processes of growth and repair? The problem of malignancy is now installed in our laboratories, and the cancer cell is being compelled to yield most reluctantly some of the complex secrets of its Bolshevist behaviour.

The old art of vital staining, which Hunter learnt from Belchier of Guy's, has taken on new improvements: by means of suitable dyes we can now select special elements in the living body, trace their movements, and note their conduct. The experimental embryologist, too, can help us if we seek to know in what manner the various tissues of the body come into existence.

Hunter: Pasteur: Lister.

These, then, are the allies of surgery in the great war: Biology in all its branches, Chemistry, Physics, Radiology. Never before has the master surgeon had such bountiful resources at his disposal. He cannot afford to neglect a single one of them. The urgent problem of our time, therefore, is a dual one: We must seek to determine the line of advance which surgery will trace in the years ahead, increasing and strengthening our alliances; and we must earnestly discover how the leaders of our army of advance are to be trained. Are the old methods, which in their day served so well, still enough; or is the form of warfare already so changed, and now so rapidly changing, that a new discipline and a wider knowledge are needed?

To answer these questions we must look backwards, and, calling upon our past experience, seek in the records of our great masters not so much what their knowledge was, but what methods they pursued as they qualified themselves for great leadership. We shall find at once that Hunter and Lister, incomparable among surgeons, each put himself through a long and arduous training, never resting in his inquiries as to the activities of living matter, as to its behaviour in health, and its reactions in disease. At the threshold of our survey we recognize that the activities of our two leaders are not unrelated. Hunter's professional life covered the latter half of the eighteenth century; Lister's the corresponding half of the nineteenth century; between them there intervened two generations of surgeons. My distinguished predecessor, the late Sir Rickman Godlee, who gave this oration in 1913, tells us in the Life of his uncle, Lord Lister,[2] that "Hunter was Lister's greatest hero"; that "his copy of Palmer's Life of Hunter was marked in many places by pencil notes which show that he was studying it at least as early as 1855"; that "a proof of Sharp's engraving of the portrait of Hunter by Reynolds, which had belonged to Syme, hung in his study"; that "he always spoke of Hunter with reverence." Further, if we turn to the paper[3] which Lister read to the Medico-Chirurgical Society of Edinburgh in March, 1858, on the "Causes of the coagulation of the blood," we find evidence of his early admiration of Hunter.

> "The nearest approach," he wrote, "which I have been able to find to such an observation [that blood which is retained in the smaller veins of the body remains uncoagulated] is contained in that inexhaustible treasury of original observations and profound reflection, the works of John Hunter."

If I may borrow a simile from the football field to express the relation of these two great men, I would say that it was Pasteur who made the final pass to Lister possible; it was Hunter's captaincy in the scrum that placed Lister in the scoring position. Indeed, we have to admit that while Hunter's resource in midfield has never been excelled, or even approached, and though the ingenuity with which he worked the surgical ball towards the goal remains unsurpassed, yet when he was in a scoring position and we were counting so confidently upon a "try," the ball was fumbled, and our hopes were foiled. The young surgeon of to-day can learn almost as much from Hunter's mistakes as from his triumphs.

Hunter's Discipline and Methods.

Let us now examine the discipline to which John Hunter submitted himself to attain his leadership. He is the "Dick Whittington" of British surgery. In September, 1748, at the age of 20, he left his home, an upland farm in the parish of Kilbride, eight miles to the south of Glasgow, and, travelling on horseback, he entered London in a little under a fortnight, alighting in Covent Garden, where his brother William kept a school of anatomy. William Hunter was beyond doubt the foremost medical teacher of his time; his best pupils caught from him the spirit of research: among his inspired disciples were John Hunter, William Howson, William Cruickshank, Charles White of Manchester, and William Hey of Leeds, the founder of the Leeds Infirmary, the first stone of which was laid in 1767 by Edwin Lascelles, the first Lord Harewood. In 1751, after three years of study, John Hunter counted himself a qualified surgeon; he remained in his brother's school to teach and to research, at what salary we cannot now tell, but assuredly it was a small one. John Hunter thus entered the critical years of his life, for the career of a young surgeon was determined then, just as it is to-day, not so much by his conduct during the years of pupilage, as by the use made of the period after qualification. The problems which a young surgeon first attacks, and the methods he employs to solve them, are suggested to him by the age in which he lives and by the school in which he has been trained. In John Hunter's youth a knowledge of the human body was being extended

by a skilled use of the art of injection. And so we find him in his earlier years following arteries to their ultimate termination, tracing the course of lymphatic vessels, unravelling the structure of the testis and kidney by means of an expert use of the injecting syringe and of the hand *lens*. He remained in his brother's school teaching and researching until the spring of 1761, when he entered his thirty-fourth year.

Here is a list of the subjects he investigated during that period. He began to note the earliest stages in the development of the chick[10] and continued this study to the end of his life, deriving from it guidance for the interpretation of the phenomena of repair and of disease. We find him exposing the thoracic viscera, using artificial respiration, and noting accurately what happened to heart and lungs when the air supply was withdrawn and when it was renewed.[11] He studied respiration in birds, keeping cocks alive which breathed through the cannulae inserted in their air sacs instead of through their windpipes.[12] He carried out a series of experiments on absorption from the bowel in various animals; the experiments were well planned and skilfully executed, but he drew from them a wrong inference—one which misled him subsequently time after time—in the interpretation of the processes of disease. He believed that these experiments proved that all the products of digestion were absorbed by the lacteal or lymphatic system, and that none entered by the veins.[13] Our hero, as we have seen, was often weak when he approached the goal posts. We find him tracing out the distribution of nerves in the nose and giving, for the first time, the right explanation of why the fifth pair of cranial nerves should enter into the field of mucous membrane supplied by the olfactory nerves.[14] The description he then gave of the descent of the testis[15] and of the vital phenomena which attend that still mysterious operation has never been surpassed. He kept a tame kite to prove that a stomach accustomed to a flesh diet could be educated to deal with one which was purely vegetarian; he noted the phenomena of digestion in the stomachs of fish, fowls, dogs; he explained *post-mortem* destruction of the stomach.[16] He placed pieces of raw meat in suppurating wounds and observed the digestive effects which followed; he measured the digestive (or tryptic) action of pus.[17] We find him deeply interested in the formation of pus upon the unbroken surfaces of serous and of mucous membranes. He began a series of observations on the uses of the vesiculae seminales,[18] and was led thereby to investigate experimentally the potent and mysterious influence which testis and ovary exercise on the development and growth of the body.[19] We find him seeking signs to distinguish between tissues in which life was latent and those from which life had already vanished. He believed he had discovered the organ of hearing in fishes, and sought to discover an explanation of the curious fact that the ovaries of eels were always destitute of ova.

As a collector—like Pascal a *ramasseur de coquilles*, who often found a pearl of great price—as an observer of incredible industry, gathering facts just for the sake of their individual value and without at the moment any care for their relative significance or for the effect of their impact upon other facts, he ranks second only to Hippocrates. But when these facts were stored in his mind and illustrated by a series of specimens he was by no means inexpert in their interpretation or in raising a general truth from a multitude of singular examples. But as we read we seem to be oppressed by the verbal difficulties he encountered. The words will not come. Even the constructive thoughts may sometimes appear to be absent, puny, or unmanageable. He cannot get his mind round them. If by chance we seem to think that he has done so, the splendour of his thought is disfigured by his uncouth language. Abernethy is not alone in telling us of Hunter's paucity of language and of his inaptitude in its use; but we need no other evidence than that which his own works rarely fail to give us. His letters are the same. Illiteracy is not absent from them, though their meaning is often clear enough, especially when express instructions are given. It is when Hunter endeavours to rise to abstract generalizations that we see this incapacity chiefly and lamentably displayed. Obscurity of language, I believe, even in abstract matters, often means obscurity of thought. Words may come after thought, but not long after, surely. Hunter's defects in language were due in part, no doubt, to the absence of any early education of value, but they were not lessened by his studious avoidance of the work of others. His rebuke to Jesse Foot, as brutal and irrelevant as many of Johnson's, would have confounded anybody, but it is irrelevant nevertheless, and it was a confession of his own imperfection.

After spending fully twelve years experimenting, John Hunter in the spring of 1761, and in the thirty-fourth year of his age, engaged in the practical work of his profession and was appointed surgeon to the army. In the summer of 1763 he returned to London on half-pay and commenced practice. He bought "a piece of ground called Earl's Court, near the village of Brompton, and two miles from Hyde Park Corner," on which he built a small house. Earl's Court, his week-end cottage, was soon converted into a zoological garden and experimental laboratory; many new problems engaged his mind and several avenues of investigation were opened up there; all of them were made to converge on the same subject—the behaviour of living matter under all conditions. It was not until 1768, when he was 40 years of age, that his private practice began to grow, enabling him to take a lease of the house, 42, Jermyn Street, vacated by his brother William. We may now consider him, after an apprenticeship of twenty years, fairly launched in practice. Three years later he considered that his income justified him in undertaking the responsibilities of marriage.

We see, then, this leader of surgery of the eighteenth century devoting twenty years of his life to arduous observation and experiment so as to qualify himself for the practice of his art. There has probably never been a man in our profession with so wide an intellectual interest, so profound a knowledge of so many varied subjects wholly derived from direct personal inquiry and observation. His industry was inexhaustible. He had no equal either as physiologist or pathologist; he was already first among comparative anatomists, and was indeed one of the founders of this science. He was a naturalist, all subjects in animal and vegetable physiology seeming to attract him. All his unequalled attainments as biologist were brought to the service of surgery, in his hospital work and finally in the largest private practice of his day. Before Hunter's time surgery was a thing apart, independent of all other sciences, ostentatiously aloof from them, and governed only by the experiences and aptitude gained in the day-to-day practice of the art. All advance was therefore slow, even when recognizable, and was largely empirical. No physiological knowledge, nor any experimental discovery, broadened the old path or opened up new ones. Hunter changed all this. Not the least of his achievements was that he made alliances for surgery, and linked it inseparably with biology. Hardly a day passed without some experiment. I may quote a statement of his to show how he regarded experiment.[20]

> "In pursuing any subject, most things come to light by accident; that is, many things arise out of an investigation that were not at first conceived, and even misfortune in experiment has brought things to our knowledge that were not, and probably could not, have been conceived; on the other hand, I have often devised experiments by the fire-side or in my carriage, and have also conceived the result; but when I tried the experiment the result was different, or I found that the experiment could not be attended with all the circumstances that were suggested."

This statement helps in some degree to explain the number of apparently unrelated subjects which Hunter explored in his younger years. As he opened a new subject, he still continued to investigate the old; at the time of his death he had over fifty portfolios in use, each relating to a particular line of investigation.

The "misfortune in experiment" has its counterpart in operative surgery. An interesting little paper might be written on "The advantage of error in medicine." We may recall Spencer Wells's operation for an "ovarian cyst," when tuberculous ascites was found and the surgical treatment of peritoneal tuberculosis inaugurated. The

same distinguished surgeon, a pupil of the Leeds school, operating upon a jaundiced girl of 18 for "fibroid tumour of the uterus," discovered that the tumour was not pelvic but splenic. He removed the spleen: in a few days the lifelong jaundice was gone, and the surgical treatment of haemolytic jaundice was begun. So McGill, the pioneer in the operation of prostatectomy—precedence in which is so foolishly claimed for others—removed what he believed to be a "tumour at the base of the bladder." When I, acting as his house-surgeon, examined the tumour microscopically and found that it was prostatic, I felt that I had the chance to twit my beloved chief with his error. His reply when I told him of his mistaken diagnosis was, "Then why don't we always take the prostate out when it projects into the bladder?"

Lister's Discipline and Methods.

When we compare Lister's preparation for professional leadership with that of John Hunter we are impressed rather by the resemblance than by contrast. Lister, the greatest material benefactor of mankind that the world has ever known, began his medical studies at University College, London, at the age of 21, in 1848, exactly a century after John Hunter had settled down to his work in Covent Garden. In the hundred years that had passed medical education in London had undergone a revolution; voluntary schools had almost disappeared, to be replaced by the organized schools and colleges with which we are familiar to-day. John Hunter was Scotch, Lister English, his ancestry coming from Yorkshire and Cumberland. John Hunter owed much to his brother, Lister still more to his father, who was not only a successful man of business, but also a Fellow of the Royal Society. William Hunter, who impregnated the mind of his brother, drew his own inspiration and owed his intellectual guidance to the Monro-Cullen school of Edinburgh. Lister was early influenced by William Sharpey and by Wharton Jones, both Edinburgh men steeped in the traditions of this very school. After qualifying in 1851, and taking the Fellowship of this College at the age of 25, Lister's first research was begun: it was concerned with the contractile tissue of the iris.[21] The injection syringe, the new instrument which had served Hunter so well, had been displaced during Lister's youth by the microscope. We rejoice, nevertheless, to notice that when Lister applied this new instrument to the tissue of the iris, it was the function rather than the form of this structure which excited his interest. In this investigation, and in another[22] begun in 1852, "Observations on the muscular tissue of the skin," we recognize that, influenced by William Sharpey, he had become familiar with discoveries made in other countries, notably with those of Kölliker in Germany. But clinical work was not forgotten, and a house-surgeoncy at University College was followed by perhaps the most critical event of Lister's life. In tracing the motives which have directed the progress of medicine we are constantly reminded of the influence and the power of great teachers. Such men are gratefully remembered by posterity—not so much for the work which their own hands or minds have created or have modified; not for their written words which so soon seem to possess little more than an antiquarian interest; not for their spoken words, which, though at the moment of their delivery they may walk up and down in the hearts of men and stir them to new thought or to great action, yet seem so frail and cold and lifeless when the morning comes—not for any of these, but for the spiritual legacy they bequeath to those trained in their own methods and inspired by their own zeal. It is this which gives posthumous life—the true immortality.

Not the least of the claims that John Hunter makes upon our reverence is that he was the first founder of a School of Surgery. He was not distinguished as teacher. "He had not the happy talent of displaying the stores of his mind, nor of communicating to others the same perception of the importance of his facts and opinions as he himself entertained."[23] Abernethy said his language was "inelegant and often coarse"; "his delivery heavy and unengaging"; "his method confused with attempts to find words for thoughts, or else to read from little scraps of paper." Yet despite these unattractive or even repellent qualities, men who themselves influenced surgery for generations afterwards, whose influence still survives—Abernethy, Astley Cooper, Cline, Everard Home, Blizard—all boasted of being his pupils, and taught his method until it became, and still remains, a tradition in their schools, and from them has spread to every school of medicine in the world, where Hunter is recognized, unchallenged, as the founder of scientific surgery. So, too, our debt to Italy will be forever unrequited while we remember that it was the magnetism of Fabricius that drew Harvey to Padua. But for Fabricius and the magic of his work the discovery of Harvey, the great glory of British medicine, might not have been made for generations.

William Sharpey, whose lectures "inspired me with a love of physiology that has never left me," had not only Lister's future, but also all that this meant for mankind, in his own hands when he sent Lister to Edinburgh to the "safest surgeon" of his day, James Syme. It was an almost incredible exodus. When the Hunters came southwards they followed a national habit established for centuries, and never permitted to fall into disuse—a habit which incited the characteristic irony of Samuel Johnson. When Lister went northward he founded a new tradition and made a novel breach in a custom which seemed to have become as firmly accepted as a law of nature. Lister's most distinguished successor in his chair of clinical surgery, my old friend Harold Stiles, made the same adventure, to Scotland's great advantage.

London hardly notes and seems but little disturbed by the arrival and the progress in her midst of young medical men from Scotland. (Whatever would she do without them?) Edinburgh, one may suspect, raised her eyebrows when she saw a young doctor from London established as Syme's house-surgeon; and she must have rubbed her incredulous eyes when, within two years, she saw him become an extramural lecturer in surgery within her own stronghold. It is quite impossible to exaggerate the importance of this teaching appointment on Lister's future. He met his students—the ultimate number in his first class was seven—on Wednesday, November 7th, 1855. Lister believed, as Hunter had believed, that the beginning of surgery was a knowledge of the process of inflammation; and accordingly he had resolved, before his lectures commenced, to obtain a new first-hand acquaintance with inflammatory processes as watched in living tissues. Clearly he realized long before the humblest of his intellectual descendants the need to study the "pathology of the living." A frog was caught in Duddington Loch—surely the greatest frog in history, honoured by being made the subject of this research. Why did not someone suggest to Lister when he was granted arms that this frog should be immortalized in heraldic device? The web of this frog's foot gave all the necessary opportunities for the inquiry. Lister had many new advantages over Hunter: he knew that the tissue he examined was made up of living units—cells; he had at his disposal a powerful microscope, which could mark the behaviour of these cells; and Claude Bernard in 1853 had taught him the existence of vasomotor nerves. It was during the examination of the frog's web that Lister made a biological discovery of the highest importance—one which experimental biologists are still exploiting: that pigment-containing cells such as are seen in the frog's web give more easily visible, and more delicate, reactions than any other kind of living cell, when subjected to a physiological or a pathological stimulus. This quality enabled him to study the effects of inflammation in terms of individual cells. He was able to prove that these pigment cells still gave vital responses fifteen days after the leg had been amputated.

The list of researches carried out by Lister between the time of his arrival in Edinburgh in 1853 and his appointment to the chair of surgery in Glasgow in 1860 would almost suggest that he was seeking to fit himself to become an experimental physiologist or pathologist rather than surgeon. I would earnestly emphasize this point, for its significance in Lister's day was far less than it is to-day, when the full harvest of his work is ready to be gathered. In most of these researches we can clearly see the strong

influence of John Hunter. It is not accident, surely, that the men who have done most for surgery trained themselves rather as research workers than as practitioners, that they revelled in and set out to master one problem after another in biology. Lister's acknowledgement of the immense influence of Hunter upon him is not in the least overstrained. If the spirit of Hunter watches over his Museum and this College, as we hope it may, how infinite must be its pride in the thought that the one man greater in service than Hunter himself was his direct intellectual offspring!

Let me recall the names of a few of Lister's early papers: that "On the flow of the lacteal fluid in the mesentery of the mouse,"[24] begun in 1853 and published in 1857, is a direct extension of Hunter's experiments on absorption;[25] the communication on "The persistent vitality of the tissues"[26] is founded upon observation made by Hunter himself on the same subject. The studies on "Coagulation of the blood" began by observing what happened in the veins of "sheep's trotters" taken from the shambles. By devising new and critical experiments he was able to carry the knowledge concerning coagulation to a point far beyond that which Hunter had reached a century before him. Yet his methods were clearly modifications of Hunter's. Lister's vocabulary, indeed, was still that of Hunter: for he spoke of the "solids" of the body, of "preternatural stimuli," of the "disposition of the tissues," of "inherent tendencies," and of "sympathetic irritation."

THE ANTISEPTIC SYSTEM: PREVENTIVE AND CURATIVE.

The events which followed Lister's arrival in Glasgow are too well known to all the world to need more than the briefest recapitulation. Lister was then 33 years of age, almost the same age as Hunter when he joined the army as a surgeon. As a result of seven years of a preparatory experimental investigation, conjoined with a wide clinical observation which was closely related to it, he had become immersed in all the problems relating to inflammation and suppuration. He had already formulated a hypothesis that suppuration was due to putrefaction, and in 1865 was ready to put his supposition to a practical test. Pasteur's epochal discovery that putrefaction was due to "germs" set matters going. Lister wrote:[27]

> "To prevent the occurrence of suppuration, with all its attendant risks, was an object manifestly desirable; but till lately apparently unattainable, since it seemed hopeless to attempt to exclude the oxygen, which was universally regarded as the agent by which putrefaction was effected. But when it had been shown by the researches of Pasteur that the septic property of the atmosphere depended, not on the oxygen or any gaseous constituent, but on minute organisms suspended in it, which owed their energy to their vitality, it occurred to me that decomposition in the injured part might be avoided without excluding the air, by applying as a dressing some material capable of destroying the life of the floating particles."

Lister was first of all concerned with the destruction of organisms after they had obtained access to wounds. He knew of the experiments with the Carlisle sewage, and of the bactericidal properties of carbolic acid. He observed carefully the effects produced upon living tissues by antiseptics, and concluded that the reparative processes in a wound were not thereby weakened. We are apt, however, to forget the gradual change that came over Lister's views, and the effect this had upon his practice: how he came to a full realization of the essential powers of defence possessed by the living tissues, and of our obligation to protect and if possible to increase them. Sir Rickman Godlee, who knew more of Lister than any man, has written that Lister before 1881, when he first told the world of his changed opinions, "had long recognized and taught that healthy living tissues exercised an inhibiting influence on the growth of micro-organisms. . . . He therefore began to wonder, whether if only slightly damaged, for example, by the incision made by a very sharp knife, the living tissues of any wound might not be able to deal with a certain number of germs by their own efforts." This we gleefully observe is a return to Hunter's work in which he recognized the "powers," "disposition," and "action" of living tissues. It may not be inappropriate to quote Lister's own words. He writes:[28 29]

> "The original idea of the antiseptic system was the exclusion of all microbes from wounds." Again, "During the operation, to avoid the introduction into the wound of material capable of inducing septic changes in it, and secondly to dress the wound in such manner as to prevent the subsequent entrance of septic mischief." Again, "In wounds already septic attempts are made with more or less success to restore the aseptic state." Again, "In speaking of the antiseptic system of treatment I refer to the systematic employment of some antiseptic substance so as entirely to prevent the occurrence of putrefaction in the part concerned, as distinguished from the mere use of such an agent as a dressing"; and further, "I always endeavour to avoid the direct action of the antiseptic substance upon all tissues."

The distinction between the preventive and the curative use of antiseptics is in many respects that existing between, on the one hand, the power of a germicide as determined by experiments *in vitro*, and, on the other hand, its capacity to destroy organisms when it is introduced among the living and the dead tissues of a wound. In the former there is a direct conflict, a clean fight between the microbe and the chemical agent. Few or none of the many intervening conditions are present which have to be considered when a bactericide is introduced into a wound cavity wherein there are multitudes of actions and reactions which even now seem very obscure and are so often conflicting.

We may therefore regard Hunter and Lister as bridge-builders; it is out of a multitude of scientific observations, of apposite inferences, and of wide generalizations that such bridges are built, stone by stone, arch by arch. Posterity will perhaps remember only the one bridge—permanent, indestructible, all-sufficing—of Lister. Across that bridge we have swarmed, a triumphant host, and a vast new territory has met our almost incredulous eyes. Hunter was forever building bridges, ambitious in design, firm in their foundations, but always left unfinished. Some day new architects will come and give them the full span which Hunter surely meant them to have. It is remarkable to note how often he anticipated the lines along which we see that modern surgery is making its advance. Cultures of both benign and malignant tissues are now being kept alive by methods which, devised by Dr. Ross G. Harrison while studying the growth of fibres from the nerve cells of a tadpole, have been rapidly developed by Alexis Carrel. John Hunter, too, tried his hand at experimental embryology. He "exposed the little animal [the chick embryo] by putting it into water heated to about 104° F. just covering the egg" and "hoped to keep it alive by these means and observe in the same chick the whole progress of growth, but it soon died"; therefore, he says "I was obliged to have recourse to a succession."[30] He was an experimental surgeon, as may be shown from the following quotation[31] from one of his lectures:

> "Here is the testicle of a cock, separated from that animal and put through a wound, made for that purpose, into the belly of a hen, which mode of turning hens into cocks is much such an improvement for its utility as that of Dean Swift when he proposed to obtain a breed of sheep without wool. The hen was afterwards killed and the testicle was found adhering to the intestines, as may be seen in this preparation where the parts are preserved."

He devised and carried out experiments to ascertain whether the growth in a cock's spur is due to a "disposition" inherent in the spur or derived from the constitution of the cock. He excised spurs from the legs of cocks and implanted them in their combs to note the rate of growth under such unfamiliar surroundings. The first vital stain ever used was madder; it was introduced to the notice of biologists in 1764 by John Belchier, surgeon to Guy's Hospital; by its experimental application John Hunter revolutionized our knowledge of bone growth and bone decay.[32] In the hands of Professor A. V. Hill the measurement of heat in living tissue has become the most delicate and certain indication of the nature of their vital reactions. The manner in which living matter reacted to

the application of heat and cold, and to a degree of heat generated in living tissues, Hunter made the subject of an endless number of investigations, all with the practical view of ascertaining how much or how little should be done to keep damaged human tissues alive.[33] Here was, as we have seen, an experimental physiologist and also an experimental pharmacologist.[34] He was a psycho-analyst;[35] he tried to inoculate an ass and a bitch with the virus of syphilis.[36] He preached the doctrine of operating at the earliest possible stage of a disease, and, placing himself in the position of the patient, said, "Nor do I go further than I now think I would have performed on myself were I in the same situation."[37] He performed experiments on the sensitive plant which are now being repeated.[38] These are only some of the points in which Hunter has anticipated modern progress.

So much for the past in its relation to our greatest men. What of the future?

THE FUTURE.

As I look forward I like to humour my fancy and indulge my dreams. Imagination, Keats tells us, may be compared to Adam's dream—he awoke to find it truth. The art of the surgeon is the pillar of science, and it is for science to discover how that almost perfect art may now be used to the fullest advantage. We eagerly await the day when disease shall not require to be checked in high career, but shall be blighted at its origin, or even denied existence, when our weapons of war shall be laid aside. That day may yet be far away, but already beyond the distant hills we see promise of the dawn. It does not, perhaps, so much or so deeply concern ourselves as those who soon must take up our task, and lead the hosts whose victory shall attain our high ideal. In due time, and in accord with ancient precedent, this country of ours, the fruitful mother of so many gifted sons, shall raise up in our schools the youths who shall go forth to conquer a crown. They will be best equipped who keep to the course, recall the methods, and are imbued with the ardent spirit of the two famous men whom we praise to-day—the two greatest surgeons the world has ever known.

Our youths must be prepared for self-sacrifice, for arduous discipline, perhaps for the most heart-breaking rebuffs, for the stern or even bitter criticism of their fellows. But there never was a time so rich in promise, so laden with rewards for those who labour with sincerity and truth. They will not travel alone. The whole army of science is in league with them, moving forward with incredible speed, eager to lay at their feet the triumphs of its astounding conquests. The responsibilities which rest on them, the intellectual accomplishments and the dedication of their lives demanded of them, are enough to cause the stoutest heart sometimes to falter. Yet, armed with the sword of the spirit and the breastplate of faith, they will remember that the happiness of life lies in its responsibilities, that true joy is found in the search for what may after a weary journey prove unattainable. Ahead lies the noblest of tasks to which they may consecrate themselves: for the lives of men are in their hands, the love, the happiness, the whole welfare of mankind. We need not fear. They will be worthy of their charge. God counts not result but effort.

EXPERIMENTAL PRODUCTION OF ACUTE AND CHRONIC ARTHRITIS AND ARTICULAR NEOPLASM BY RADIUM.*

(With Special Plate.)

BY

A. G. TIMBRELL FISHER, *M.C.*, M.B., CH.B., F.R.C.S.,

LATE HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS.

A FEW years ago, in a Hunterian Lecture on osteo-arthritis, I ventured the opinion that the peculiar proliferations of bone and cartilage often occurring in the more chronic form of arthritis usually known as osteo-arthritis, some of which attain a very considerable size, were intermediate between a frankly inflammatory process and a genuine neoplasm. The difficulty experienced in distinguishing between the two was so great that some of the loose bodies occurring in osteo-arthritis were designated "synovial chondromata" by Professor Shattock and myself. It is unnecessary to enter now into the histological differences between such forms of proliferation and frankly inflammatory developments. It is interesting to note, however, that the form of chronic arthritis usually known as "rheumatoid arthritis" or "chronic arthritis of the synovial or mixed types" (Fisher) is a frankly inflammatory process, whereas the proliferative changes in the so-called "osteo-arthritis" belong to the peculiar type of proliferation akin to new growth that we are considering. It is interesting to note also that the age incidence of osteo-arthritis or chronic arthritis of the chondro-osseous type is, as a general rule, very similar to that of many forms of malignant change, particularly the carcinomatous—that is, they both occur when the resistance of the body to irritation of *moderate* degree of intensity is beginning to diminish because the patient has passed the meridian of life. In younger organisms the vascular response to irritation of slight or moderate intensity is marked, and, combined with a moderate degree of cellular proliferation, probably suffices to cope with minor degrees of irritation.

After the meridian of life is past the vascular reaction is not so much in evidence, and a slight but persistent form of irritation tends to bring about a proliferation of cells that are fairly well nourished but degeneration of cells whose nourishment is poor. A good example of this is seen in "osteo-arthritis." The physiological basis for the changes in the latter is that while the central part of the articular cartilage which is devoid of blood vessels is poorly nourished, the extreme lateral portions receive blood vessels from the circulus articuli vasculosus. Irritation, therefore, whether mechanical or toxic, tends to cause degeneration of the central portion of the articular area and proliferation of the lateral portions. We observe this same peculiar admixture of proliferation and degeneration in many forms of true neoplasm, both innocent and malignant. It appears that in new growths we are faced with an essential alteration. There is a breaking down of the physiological harmony between cells and the inhibiting intercellular substance. We can imagine, for example, that prolonged irritation or toxaemia might have, simultaneously, a stimulating effect upon cells but an inhibiting effect upon intercellular substance. On the other hand, inhibition might be at a very low ebb from the degeneration of old age, and might, in a person with suitable disposition, cause a growth to develop. If inhibition is temporarily abolished but eventually recovers, a so-called innocent new growth may result, which after a time ceases to develop actively. If inhibition is impaired a subinflammatory process such as osteo-arthritis develops (compare prostatic adenomata). If it is severely impaired and the irritation is moderate, or if it is slightly impaired and the irritation great, or if irritation is great and inhibition severely impaired, a malignant growth results.

As according to this theory the condition known as "osteo-arthritis" is a stage intermediate between inflammation and new growth, it seemed to me that it might be of considerable interest to ascertain whether it would be

* The expenses of this research were defrayed by the Medical Research Council.

possible to bring about osteo-arthritis and new growth experimentally through the same agency, and for this object tubes containing radium were introduced into the knee-joints of rabbits. The following experiments show the results obtained.

A. *Experiments with Radium contained in Glass Tubes.*

Fig. 1 represents the left knee-joint of a full-grown rabbit, and shows well marked proliferation of the cartilage of the inner and upper margin of the trochlear surface of the femur.

Experiment 20 (*Old Series*).—The left knee-joint of a rabbit was opened by an incision upon the internal aspect and under strict aseptic precautions. A glass tube containing 0.0382 mg. of radium bromide was fixed by a catgut suture against the inner margin of the trochlear surface, and the joint carefully closed by suture. The joint was immobilized as far as possible by several layers of gauze saturated with collodion. A glass tube containing 0.15 mg. radium bromide was fixed in a similar position in the right knee-joint. The rabbit remained perfectly healthy, and nineteen weeks later was killed. The left knee-joint revealed the presence of a large chondro-osteophyte similar to those seen in osteo-arthritis (Fig. 1). It had developed from that portion of the articular edge opposite to where lay the radium tube, which had formed for itself an oblong shallow pit in the adjacent part of the internal femoral condyle. The remainder of the joint showed no obvious change beyond localized synovial hypertrophy in the vicinity of the radium tube. The right knee-joint showed similar changes, but to a lesser degree.

Experiment 19 (*Old Series*).—The left knee-joint of a rabbit was opened as above, and a glass tube containing 0.15 mg. of radium bromide was fixed against the inner border of the internal condyle of the femur. The animal was killed four weeks later, and it was noted that well marked proliferation of the lateral part of the cartilage had occurred at the junction of the internal condyle with the trochlear surface of the femur. A patch of fibrillation of the cartilage had occurred more centrally. Localized synovial hypertrophy was again present.

Experiment 6 (*New Series*).—A glass tube containing 0.15 mg. of radium bromide was introduced into a similar position in the right knee-joint of a rabbit. Two weeks later the animal died, and it was noted that no alteration in bone and cartilage had occurred, but that a localized villous synovitis was present in the immediate vicinity of the tube.

Experiment 5 (*Old Series*).—A glass tube containing 0.15 mg. of radium bromide was introduced into the suprapatellar pouch of the right knee-joint of a rabbit. Fourteen months later the animal was killed. The radium tube had created for itself a deep pit above the trochlear surface. Slight osteo-arthritic changes were present. An interesting feature was the fact that the patella had become dislocated, and lay upon the outer side of the femoral condyle. Here an articular surface had developed for the patella with a covering of newly formed articular cartilage (Fig. 4).

B. *Experiments with Radium contained in Platinum Tubes.*

Experiment 2 (*New Series*).—The left knee-joint of a rabbit was opened from the inner side under scrupulous aseptic technique, and three platinum tubes containing radium were introduced as follows:

Platinum tube No. 151, containing 1.2 mg., into the outer part of the suprapatellar pouch.

Platinum tube No. 152, containing 0.50 mg., into the lower and anterior part of the joint.

Platinum tube No. 153, containing 0.51 mg., into the inner part of the suprapatellar pouch. Total 2.21 mg.

After an interval of several weeks the animal developed acute destructive suppurative arthritis of a fulminating type, which necessitated its destruction. It is highly improbable that the infection was introduced at the time of the operation owing to the interval that elapsed.

Experiment 1 (*New Series*).—The left knee-joint of a rabbit was opened from the inner aspect, and platinum tube No. 150, containing 2.44 mg. of radium, was introduced into the joint. The animal was killed eleven months later, and the following conditions were observed (Fig. 2). A condition of chronic arthritis of mixed type or "rheumatoid arthritis" had developed. The radium tube lay in front of the crucial ligaments. The articular ends of both tibia and femur were considerably enlarged from inflammatory thickening of the periosteum. Considerable destruction of the articular surfaces of both femur and tibia had occurred, associated with the formation of chondro-osteophytes at the articular margins. This formation of new bone was particularly well marked from the antero-internal part of the internal tibial condyle, where a very large osteophyte had developed (see drawing). Adhesive ankylosis occurred in places between the adjacent surfaces of the femur and tibia. The synovial membrane was inflamed, and in places invaded the articular surface in the form of pannus.

Experiment 4 (*New Series*).—The left knee-joint of a rabbit was opened from the inner side. Two platinum tubes, one containing 0.22 mg. and the second 0.24 mg. of radium bromide, were introduced into the joint cavity (suprapatellar pouch). The animal was killed fourteen months later, and the following interesting conditions were observed (Fig. 3).

The joint was enormously enlarged, partly from a fluid swelling occupying the inner part of the joint and partly from a hard tumour-like mass growing from the lower end of the femur and projecting backwards into the popliteal space, but also inwards. On carefully opening the joint it was seen that the fluid swelling on the inner side was an abscess cavity, containing thick, curdy, purulent fluid, and in which the radium tubes lay. Internally the cavity had a dense fibrous wall, whereas externally the wall of the abscess cavity was formed by the enlarged lower end of the femur. In sagittal section the shape, size, and general relations of the tumour are demonstrated clearly. It is seen to be developing principally from the inner and posterior aspects of the lower end of the femur; to be of a somewhat dense and compact consistency, and to be covered externally by a tough periosteal envelope. Histologically the tumour is clearly an ossifying periosteal sarcoma which has originated from the periosteum covering the intra-articular portion of the diaphysis and the adjacent portion of the epiphysis of the internal femoral condyle.

I am indebted to Professor H. M. Turnbull, Director of the Pathological Institute, London Hospital, for the following report upon the tumour:

The peripheral portions of the mass for a considerable depth consist of a very cellular tissue that is invading and destroying muscle. The cells are spindle-shaped, triangular, polygonal, and spherical, vary greatly in size, but are for the most part large. Deeper in the mass very numerous swollen collagenous fibres appear among the cells, and gradually enlarge to form a close irregular meshwork of very narrow osteoid trabeculae. As still deeper layers are followed the trabeculae become gradually stouter, and enclose larger medullary spaces, in which lie essentially similar, usually degenerated, cells; these trabeculae are of coarse-fibred bone, are for the most part necrosed, and are arranged very irregularly. In the section from the maximal convexity of the mass some large medullated nerves are included in this tissue, and the adventitia of an artery is replaced by the polymorphic cells. The femur as it touches the mass is cut tangentially; the mass replaces the periosteum, but the corticalis is neither necrosed nor interrupted. The medulla of this portion of femur is, however, filled with a close meshwork of trabeculae of necrosed coarse-fibred bone, with some superimposed finely fibrillated bone or osteoid tissue; the medullar spaces contain the polymorphic cells, and these cells show extensive degeneration and necrosis. Similar cells fill some of the inner Haversian spaces and canals of the corticalis. There are a considerable number of leucocytes within the mass and in places close to it; there are leucocytic thrombi in some large vessels near the mass, and there is much perivascular infiltration with plasma cells in the muscle at a distance from the mass.

The conditions to be separated for a diagnosis are: (1) inflammation leading to bone formation, (2) callus formation following trauma, and (3) neoplasm. The features which I have tried to sketch in the description, particularly the wide peripheral zone of destructive cellular infiltration, make, I think, the diagnosis of osteo-sarcoma undoubted. There is some inflammatory infiltration in the mass and in the tissue beyond the mass, but this infiltration is relatively insignificant, and is such as is frequently found in association with malignant neoplasms. The sections alone do not suffice to settle the origin of the growth, but, taken in conjunction with your pictures, there can be little doubt that the sarcoma arose in the periosteum of the femur, and had invaded the medulla nearer the centre of the mass than the site of the section that includes femur.

I conclude that the condition is an osteo-sarcoma of the periosteum of the lower end of the femur.

It is not claimed that these experiments are anything more than suggestive, and it is obvious that confirmatory evidence will be necessary. The first fact that demands our notice is that, in the series of experiments with small quantities of radium contained in glass tubes, the reaction of the joint elements was slight or moderate and took the form of proliferation of the better nourished edges of the articular cartilage or synovial hypertrophy in the vicinity of the tube. The experiments were conducted under rigid aseptic technique, and suppuration did not occur. The localized proliferations at the edges of the articular

FIG. 2.—Rabbit A. 2.44 mg. of radium bromide were introduced into the left knee-joint. Animal died eleven months later. A subacute arthritis is present with a mixture of degeneration and marked bony hypertrophy. The articular ends are greatly enlarged, and below and internal a large detached osteophyte is present. Associated with the degeneration of the central poorly nourished portion of the articular cartilage is definite proliferation of the better nourished lateral portion. (Experiment 1, new series.)

cartilage were similar to those seen in osteo-arthritis, particularly in the more localized "traumatic" forms.

In the second series of experiments, with larger quantities of radium contained in platinum tubes, a striking fact was the severity of the reaction. Although scrupulous aseptic technique was used, suppuration occurred in a large proportion of cases. It is probable that the suppuration was not introduced at the time of the operation, but was due to auto-infection, for it is known that bacteria settle in damaged tissues.

In Experiment 2 (new series) the total quantity of radium in the three platinum tubes introduced into the left knee-joint of the rabbit was 2.21 mg., and acute destructive arthritis of fulminating type supervened.

In Experiment 1 (new series) one tube containing 2.44 mg. of radium was inserted into the joint, and at the end of eleven months a marked degree of chronic arthritis of "rheumatoid arthritis," with a combination of destruction and hypertrophy, was found.

In Experiment 4 (new series) two platinum tubes containing a total quantity of 0.46 mg. of radium were inserted. At the end of fourteen months a localized abscess was found combined with a large sarcomatous growth.

We have already noted that in the experiments with radium contained in glass tubes changes akin to localized osteo-arthritis accrued. In the three experiments with radium in platinum tubes the results may be summarized as follows:

Experiment 2: Acute suppurative arthritis.
Experiment 1: Subacute arthritis of mixed type similar to "rheumatoid arthritis."
Experiment 4: Localized abscess and sarcoma.

It would be rash to form conclusions from a small series of experiments, but it would appear that the smaller quantities of radium contained in the glass tubes caused proliferative changes only. The larger quantities of radium contained in the platinum tubes caused destructive changes, whereas the smaller quantity in Experiment 4 caused the marked and irregular proliferation of a malignant growth. The resistance of the animal and the time factor are, of course, important.

THE AURICULO-VENTRICULAR BUNDLE IN THE BIRD'S HEART.

(With Special Plate.)

BY

M. R. DRENNAN, M.A., M.B., F.R.C.S.E.

(From the Anatomy Department of the University of Capetown.)

In fishes, amphibia, and reptiles the muscular wall of the auricles of the heart is continuous with that of the ventricles. In mammals the muscular continuity is almost completely interrupted by the fibrous auriculo-ventricular rings. The very attenuated auriculo-ventricular bundle (bundle of His) is the only direct neuro-muscular connexion between the auricles and the ventricles. The existence of this structure, in a more or less definite form, has now been demonstrated in the whole mammalian group.

In the heart of the bird, however, the presence of the bundle of His has not, so far as I am aware, been established. Keith and Flack (1907), in an important paper dealing with the "Muscular connexions of the primary divisions of the vertebrate heart,"[1] seemed to have no doubt that there was an auriculo-ventricular bundle in the birds' hearts which they examined. On the other hand, Mackenzie and Robertson (1910), in a paper dealing with "Recent researches on the anatomy of the bird's heart,"[2] state emphatically that "in the bird's heart there is no bundle of His, or other specialized form of muscle tissue connecting the auricles with the ventricles." These same authors state that "Tawara's monograph leaves the impression that the bird's heart resembles the mammalian heart in the possession of a special muscle system. He refers to fibres of the Purkinje type in the region of the blood vessels (of the bird's heart)." Dr. Alexander Morison (1912), in his paper "On the innervation of the sino-auricular node,"[3] states in his argument that in birds "most investigators have failed to find the auriculo-ventricular bundle; not that this fact proves its absence."

The presence or absence of this structure in the bird's heart would seem, therefore, to be "not proven." Yet it seems to me that it is very important that an attempt should be made to decide this question. If the bird's heart can dispense with a bundle of His, it suggests that the physiological importance of the bundle is perhaps being overrated in the mammal. On the other hand, if the bundle can be proved to be present, it brings this heart and its contractile phenomena more into line with that of the mammal, and adds to the significance of this structure in cardiology.

Most workers hitherto have relied on the findings from a microscopical investigation of the hearts of small birds, but it would appear that such an examination is unsatisfactory from the fact that the bundle fibres, if they exist, appear to be little differentiated from the ordinary heart muscle. Keith and Flack[1] state that in birds they "have been unable to find any differentiation of fibres in the bundle; the guide to it being its position and its definite demarcation by fibrous tissue. In the birds' hearts examined (sparrows and goldfinch) the A-V bundle arises from the auricular ring and dives at once into the interventricular septum."

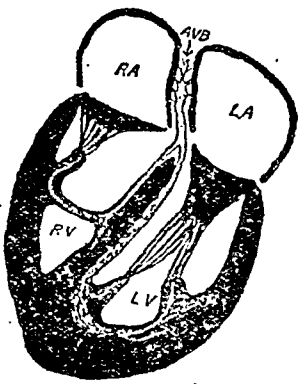

FIG. 1.—Scheme of the distribution of the A-V bundle in the human heart.

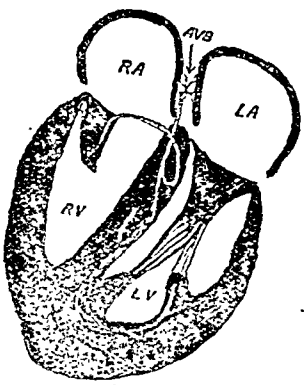

FIG. 2.—Scheme of the distribution of the A-V bundle in the ostrich's heart.

I have recently dissected five ostrich hearts with a view to determining whether any trace of a bundle could be detected with the naked eye. The size of these hearts—they are as big as a small ox heart—gave promise that, if there was a bundle, it would be of tangible size. In all of these hearts I have been able to demonstrate a structure which is probably homologous and analogous to the auriculo-ventricular bundle in the mammal.

This structure is not so easily defined as the auriculo-ventricular bundle in the ox, but it is nevertheless as definite as the auriculo-ventricular bundles which I have been able to trace out in the human heart. It arises in the same region as the mammalian bundle, but there is no sign of any definite auriculo-ventricular node at its commencement. In several of the hearts, however, I was able to make out a rich nerve supply to this region from the right coronary plexus. At its commencement this structure is pale and delicate, varying in thickness in the different hearts examined. It is best made out by approaching it from behind, by separating the right and left atrial walls in the region of the interauricular septum (see Plate, Fig. A). It passes through the medial aspect of the right auriculo-ventricular fibrous ring, just under the endocardium, to which it is adherent. As soon as it reaches the interventricular septum it plunges deeply into its substance (see Plate, Fig. B), and runs obliquely towards the left side of the septum. Here, on the septal wall of the left ventricle, it divides at once into a large number of branches, which form a network just under the endocardium (see Plate, Fig. C). The distribution of this part of the avian bundle is very similar to that of the left branch of the mammalian bundle.

In the ostrich heart there is no branch of this bundle tissue having a distribution similar to that of the right

branch of the mammalian bundle—namely, running down the right side of the interventricular septum to the moderator band, etc. (see Fig. 1). There is a branch, however, which is analogous to this one, but it takes a very different course. As the avian bundle passes through the interventricular septum it gives off a branch, which runs in a curved direction to the left, then upwards and to the right, to end in that wonderful single muscle valve which in the bird's heart takes the place of the mammalian tricuspid (see Fig. 2). This avian muscle valve consists of a wedge-shaped mass of muscle, which extends from the upper limit of the right auriculo-ventricular opening to its lower part. It is situated on the lateral aspect of the opening, and it becomes closely applied to the septum when the right ventricle is in systole. It has no chordae tendineae nor musculi papillares. This marked difference in the arrangement of the right auriculo-ventricular valve in the bird, as compared with the mammalian tricuspid, accounts for the very different course taken by the right branch of the bundles in the two hearts. On the other hand, the similarity between the avian and the mammalian mitral valves, and the almost identical distribution of the left branches of avian and mammalian bundles, has its significance. From the above considerations it looks as if the avian and the mammalian bundles have a similar function.

The general naked-eye characters of the auriculo-ventricular bundle vary very much in different mammals, and even in different individuals of the same species. In the ox heart the bundle is relatively thick, smooth, and rounded, and more like muscle tissue than the human bundle, which is thin, ragged, and pale, like a fine nerve fibre. In the ostrich heart the bundle is more like glistening fibrous tissue. This shiny appearance is more marked on the left side of the bundle than on the right, and on this aspect the bundle is easily separated from the heart muscle. Elsewhere the bundle is adherent to the muscle fibres, and it presents a ragged appearance when dissected out. Within the septum the bundle tissue gives off several fine white branches to the heart muscle in addition to the curious right branch already described. The individual variations of the several bundles dissected out in the five ostrich hearts are very considerable, especially as regards size and definition of the bundle system.

CONCLUSION.

The ostrich heart presents a system of fibres which is somewhat similar to the auriculo-ventricular bundle of the mammalian heart. The distribution of this system is such as to indicate that it has a similar function to the bundle of His—in short, that it constitutes a true avian auriculo-ventricular bundle.

THE OSTEO-PERIOSTEAL GRAFT IN DANGLE-FOOT.

(With Special Plate.)

BY

JOHN GILMOUR, M.S., F.R.C.S.,

HONORARY ASSISTANT SURGEON, ROYAL VICTORIA INFIRMARY, NEWCASTLE-ON-TYNE; ORTHOPAEDIC SURGEON, W. J. SANDERSON HOME FOR CRIPPLED CHILDREN, GOSFORTH.

IN *Surgery, Gynecology and Obstetrics* for February, 1926, Professor Rutherford Morison and Dr. William Mackenzie describe an "operation for dangle-foot" in which they use osteo-periosteal grafts to stabilize the ankle-joint. These grafts are taken from the patient's tibia, and are implanted to form osseous ligaments between the tibia and fibula above, and the astragalus and os calcis below. Two procedures are described:

(1) *Posterior grafts*—extending from the back of the tibial and fibular epiphyses to the sides of the os calcis below.

(2) *Lateral grafts*—stretching from the outer aspects of the malleoli above to the peroneal area of the os calcis externally, and to the inner aspect of the astragalus and os calcis below.

During the last year I have been associated with the authors at the W. J. Sanderson Home for Crippled Children at Gosforth, and I have had repeated opportunities of examining the efficacy of these procedures in fixing the ankle and subastragaloid joints, and of extending the principle in other directions. Time has shown that uniformly good stabilization is secured, and evidence is accumulating to demonstrate the superior value of the method.

In a number of cases of flail-foot astragalectomy had been performed to produce fixation, but the results were generally disappointing. It was found that there was a marked tendency for the foot to become fixed in a varus position, due partly to the over-development of the os calcis externally, partly to the irregular development of fragments of cartilaginous bone in place of the astragalus, and partly to the natural shortening of the longitudinal arch of the foot on the inner side after astragalectomy.

Other operations in which bone is removed to shorten the tarsus, and to arthrodese the astragaloid joints, are apt to leave the patient with feet that are unequal in size, and to present to him the ever-recurring problem of getting boots for feet which are not neighbours.

The paralytic foot is already often smaller than its fellow, and its bony tissue is thin and largely decalcified. For this reason alone it would seem to be better to fix such a foot by introducing bone, which may at the same time exert an osteogenic stimulus, than by removing it.

The illustrations show how remarkable is the growth of bone from the thin osteo-periosteal shavings which were used as grafts in these cases. The purpose of this communication, however, is to draw attention in this operation to the importance of accuracy in the process of embedding the grafts, and to illustrate the interesting though undesirable results which occurred in one case where the graft extended beyond the tibial epiphysis and gained an attachment over the epiphyseal cartilage to the diaphysis.

The case is that of a boy, aged 14 years, who had a paralytic dangle-foot on the left side. For this disability two posterior osteo-periosteal grafts were implanted on January 19th, 1925. Radiographic examination showed the grafts in position but reaching up over the epiphyseal "line." After fixation for six months the plaster-of-Paris casing was removed and the foot was again radiographed. Fig. 1 shows the two posterior grafts behind the ankle and subastragaloid joints. Their upper limits appear as bony shadows beyond the tibial and fibular epiphyses, the lower ends are seen to be blending with the bony texture of the os calcis. It is important to notice that the long axis of the tibial shaft is at right angles with the plane of the "epiphyseal" cartilage.

The boy was now (July 1st, 1925) permitted to walk about on this foot with no other support than the grafts. Fig. 2 is a radiogram taken six months later (December 9th). It shows how the grafts have become consolidated, and how the bones have increased in density. The upward extension of the grafts beyond the epiphysis is clear. Clinically, there was good fixation at the ankle, but a mild degree of equinus deformity. The radiogram shows this distinctly: the shaft of the tibia no longer makes a right angle with the plane of the epiphyseal cartilage, but is inclined backwards from it in a manner which is comparable to the inward deviation of the femoral shaft to its lower epiphysis in cases of genu valgum. This can only be due to the freer growth of bone at the front of the tibial epiphyseal cartilage, the posterior region having been fixed down, as it were, by the binding pressure of the grafts.

The ultimate result in this case would naturally be spoilt by the further development of this bony deformity causing a fixed equinus. Indeed, it is possible that the amount of equinus already present was enough to cause this boy to jar his foot and fracture one of the grafts two months later. Attention was called to the fact by his complaint of pain at the back of the ankle, and the third radiogram (Fig. 3) shows this condition (February 11th, 1926).

The presence of pain and the fracture in the graft are recorded as interesting features of this case, since radiographic examination of other cases occasionally shows clear areas in the graft without there being any history of pain in the neighbourhood. It is not yet certain that these areas of rarefaction are fractures; they may be, but it is fortunately true that their appearance has not interfered with the clinical results. The radiogram shows very clearly the increasing tibial deformity. Professor Morison's instruction that the grafts should extend up to but not over the

epiphyseal line is seen to be of primary importance. They are to be used as osseous ligaments, and should retain sites of implantation corresponding with ligamentous attachments. In the neighbourhood of growing epiphyses due regard must be paid to the laws of growth. This case may therefore be looked upon as an instance of the extraneous fixation of the epiphysis to the diaphysis (by a graft), which the late Sir William Macewen showed would interfere with or prevent normal linear growth.

A CASE OF ARTIFICIAL PNEUMOTHORAX.

(*With Special Plate.*)

BY

BERNARD HUDSON, M.D.CANTAB., M.R.C.P.,

SWISS FEDERAL DIPLOMA; MEDICAL SUPERINTENDENT, VICTORIA SANATORIUM, DAVOS-PLATZ, SWITZERLAND.

A MAN, aged 26, was under treatment for eighteen months (1922-23) for pulmonary tuberculosis affecting the upper lobe of the right lung. Recovery was excellent, and, by the sanction and advice of his doctors, he went to Kenya Colony in September, 1924, and invested in a farm there. The place suited him, and all went well until some months ago, when he became very ill, apparently (as far as can be made out from the history) with an acute exacerbation, which spread rapidly through the right lung, but chiefly affected the base. He saw a doctor, who advised him to get away as quickly as possible, and go straight to Davos-Platz. He arrived here under my care on February 22nd, 1926. He was exceedingly ill on arrival, the daily temperature varying from about 99° in the morning to 102° and over at 7 p.m. (taken by the mouth). He had a racking cough, and was bringing up a large quantity of sputum loaded with tubercle bacilli; he had lost about 2 st. in weight, and was looking a typical picture of what is known as "galloping consumption."

On examination the whole of the right lung was dull, and the lower half absolutely so; the whole lung was full of moist râles, and at the base there was *loud bronchial* breathing, increased vocal resonance, and increased vocal vibrations. Some moist crackling râles were heard in the upper lobe of the left lung, and the disease apparently had well started in this lung.

The radiographic appearance (Fig. 1) showed extensive trouble in the right lung, cavitation at the apex, and a dense black shadow in the lower part. It will be seen that the heart is drawn well over to the right side; the left lung shows commencing tubercle in the upper lobe. The appearance of this radiograph made me consider the possibility of an effusion at the right base, and I accordingly explored with a large-bore needle, but got nothing out. As the patient was obviously going downhill, and showed no signs of any improvement, I thought it worth while to see if it would be possible to establish an artificial pneumothorax on the right side, although there seemed very little hope of being able to do so, because of the probable presence of strong adhesions. However, on March 13th an attempt was made, and, to my great astonishment, a free space was found at once, the manometer swinging well, showing a strong negative pressure; 150 c.cm. of air only was introduced and a small initial pocket made. This amount of air sufficed to raise the pressure from a negative one to a strongly positive one, the pressures being as follows:

Induction	−2 −6	...	150 c.cm.	...	+2 −4
March 16th	−2 −6	...	200 c.cm.	...	0 +3
March 21st	−2 −7	...	300 c.cm.	...	+1 −4

A radiograph taken shortly afterwards showed the production of a small pocket (Fig. 2). Two more insufflations were made, the results being as follows:

March 31st	−2 −7	...	300 c.cm.	...	0 −3
April 10th	−3 −8	...	500 c.cm.	...	0 −1.5

The fillings were continued at intervals of a fortnight, about 600 c.cm. being introduced each time, and the radiograms (Figs. 3 and 4) show the development of a fair-sized artificial pneumothorax in the lower part of the right lung, many adhesions having given way, but leaving two or three powerful bands, which are very plainly seen in the illustrations.

An interesting point is that after the third insufflation the patient remarked that he felt his heart once more beating on the left side instead of on the right. On inspection of Figs. 3 and 4 it will be seen that the heart, which was formerly drawn over to the right side by adhesions, has returned to its proper position on the left.

July, 1926.—The pneumothorax, although only a partial one, caused an undoubted and pronounced improvement in the patient's condition. The cough and expectoration have very much diminished, the pulse rate, instead of being 120 to 130, is now running at about 80, the breathing is easier and quieter, and the temperature has come down. The patient is now getting up for a short period each day without any ill effects. The signs in the left lung are diminishing in extent and intensity.

February 1st, 1927.—The further progress of this case is as follows: The patient kept very well all through the summer, and was able to take moderate exercise, the temperature being always quite normal, and the cough and the sputum diminished. The general condition improved considerably, and he gained weight. Fillings were continued every three weeks, the pneumothorax cavity gradually increasing in size, and the adhesions thinning and stretching. On January 17th the patient's temperature began to rise again, and he developed pain on the side of the pneumothorax; this was shortly followed by the appearance of a small serous effusion, which is following the ordinary course of such effusions; and the patient is already improving daily. Incidentally it is of interest to note that with the establishment of this effusion the adhesions have given way, the pneumothorax now being nearly "complete"; the other lung is holding up in a very satisfactory manner.

I am indebted to Mr. P. G. Sutton, M.S.R., of the X-Ray Institute, Davos-Platz, for the radiographs.

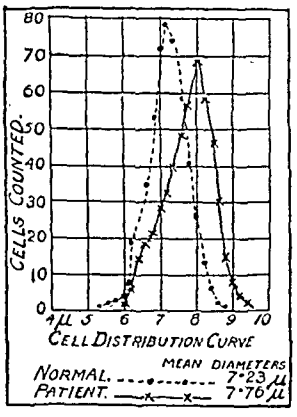
PARAPLEGIA (MEGALOCYTIC) CURED BY *HYDROCHLORIC ACID.*

BY

FRANK C. EVE, M.D.CANTAB., F.R.C.P.LOND.,

SENIOR PHYSICIAN, ROYAL INFIRMARY, HULL.

DIAGNOSIS in the following case was possible by measuring the average diameter of the red cells, and by that alone. Haematology, and all its complexities, gave no light. How forcibly this illustrates my favourite doctrine that simple recorded measurements in clinical medicine are richly rewarded, yet greatly neglected.



A florid, healthy, active young man of 37, a cargo superintendent, decent and clean living—noticed tingling in both legs up to the groins in January, 1925; later his hands tingled, he was drowsy, and had sacral pains, worse on walking. Next his ankles gave way, micturition became difficult, and the pavement felt like cotton-wool.

He was much worried sexually at this time by the exactions of his second wife, to whom he had been married a few months. In July he could no longer walk, and in August I saw him in consultation with Drs. Eddie and Robertson. I diagnosed posterior combined sclerosis, and he was admitted into the Royal Infirmary under my care. There he lay on the balcony for five months, and then went to the seaside under Dr. Sproulle. The plantar reflexes were extensor, knee-jerks absent, and he could not move his feet. Hydrochloric acid was not present in the test-meal secretions, and *x* rays were suggestive at first of pyloric new growth, but became normal after belladonna. Haemoglobin was 75 per cent., and the pathologist reported more than once that there was no evidence of pernicious anaemia. As he had had sore tongue before admission I still felt incredulous.

In view of the recent illuminating work of Dr. A. F. Hurst on this subject I ventured to send him a blood film and an outline of the case. At his instance, Dr. Hampson kindly carried out the measurements of

the red cells shown in the curve. Dr. Hurst wrote (February 18th, 1926):

"The average size of the red cells is increased, so that there is the megalocytosis which is characteristic of Addison's anaemia. We find not infrequently that in the early stages this is the only evidence of Addison's anaemia—a general examination pointing to quite normal blood or slight anaemia of a secondary type, but I believe the megalocytosis is conclusive evidence."

Presumably the interpretation of the case is that, owing to the absence of hydrochloric acid, his intestines became infected with some germ which is capable either of producing the haemolysis of pernicious anaemia or of causing the degenerative changes in the spinal cord. Probably the sexual exhaustion was a factor in deciding the incidence on the spinal cord; for doubtless our medical forebears had good reasons for attributing tabes to sexual excess before its syphilitic nature had been ascertained.

Treatment.

He had four teeth extracted, and massage. He drank half a pint of hydrochloric acid three times a day after food, and must continue to do so all his life, as the deficiency is doubtless congenital. Its strength is 5 drachms of dilute hydrochloric acid to the pint of sweetened water. He had twenty-four hours' fresh air every day for four months; besides sunshine, he had two hours a week of ultra-violet rays from three carbon arc lamps running at 30 per cent. over pressure, according to my system.[1] To the latter he himself largely attributed his cure. I find that they nearly always make a medical patient feel better—which is half the battle won. Hence they are a very useful addition to a general medical ward.

After a month or so in hospital he gradually improved, and walked after fifteen months' illness. His gait is now brisk, with only a hint of spasticity. He looks well, can run, and has been at work for three months clambering about ships. His legs and finger-tips still tingle. Haemoglobin is 100 per cent., sensation is normal, and the knee-jerks have returned, but the extensor plantar reflex persists.

"When once these cases are bedridden improvement is unusual"; so that his recovery is remarkable, and is due, I think, to the hydrochloric acid. Hitherto a case of this kind would be foredoomed to Addison's anaemia. It will be interesting to see if the hydrochloric acid habit will save him from this fate—of which he has been warned.

HABIT FORMATION IN THE BLOOD VESSELS OF THE SKIN.

BY

P. B. MUMFORD, M.D., M.R.C.P.

SUPERFICIAL blood vessels appear to possess a property of retaining for a variable period an altered sensibility to stimuli, whether internal, external, chemical, thermal, mechanical, or nervous. A vessel by the constant use of its power of contraction or dilatation may acquire the habit of so responding to the same degree when the stimulus is lessened or when another form of stimulus is supplied. Hypersensitivity may remain in a skin vessel for a considerable period after the application of the original stimuli. Certain phenomena demonstrate these peculiar properties, but in mentioning them it should be realized that the alteration of reaction is not always specific and that there may be an altered response to other forms of stimuli.

A. *Mechanical Stimulation.*—When an area of skin is subjected to a pressure of about 2 lb. by stroking with a round bobbin of wood the vascular changes, active and passive, which follow will disappear within a few minutes. If the skin be now immersed in *hot* water it will be found that the line of the stroke reappears as an area of more marked erythema than the surrounding skin. The line represents an area of hypersensitivity. The line shows also a much slower return to normal.

B. *Thermal Stimulation.*—Prolonged exposure of the skin to heat will often leave vessels very responsive to stimulation. A stoker who had been accustomed to wear a singlet which covered the lower chest and abdomen showed a very marked response to dry and moist heat; the response was especially deep over the exposed areas. Similar excessive vascular dilatation is to be found in many other persons who make a continual demand on the skin for heat excretion power. Hyperthyroidic individuals flush up very freely in heat. One of the "excuses" generally given for the morning cold bath is that by exposure of the body to a sudden cold medium the arterioles and capillaries of the skin are taught to react quickly and actively. By the phrase "acclimatization" is meant the adjustment of the superficial blood vessels to changed surroundings and changed metabolic level.

C. *Chemical Stimulation.*—When an area of skin has been chemically irritated there may remain for a considerable period an oversensitiveness of that area even though all trace of lesion has gone.

A woman who had had a severe fur dermatitis on the neck returned in three weeks with severe irritative dermatitis over the same area of skin; apparently it had followed the exposure of the neck to very cold winds. After this had settled down she again had a severe relapse over the original areas due to the use of carbolic soap. In each case the relapse had followed the exposure of the whole face and neck, and yet the only portions of skin affected were those which had been left in a hypersensitive condition by the original fur dermatitis.

D. *Infective Stimulation.*—The skin around areas of mild inflammation (acne follicles, pustules, etc.) shows a more marked response when subjected to mechanical irritation than do the intervening areas. For example, in a case where there had been a bromide eruption the areas where there had been lesions developed an urticarial response when they occurred in the path of a heavy flat stroke stimulus. When the whole body was immersed in warm water the areas of injury stood out as points of deeper erythema. Patients suffering from acne rosacea will often volunteer the information that a heated room causes the sites of disease to reappear after their apparent cure. This apparent manifestation of "habit" cannot altogether be explained as due to the fact that areas of infection are of higher temperature (Lewis), since they are found when all traces of disease have disappeared. The temperature change may, however, explain the development of wheals over patches of acute seborrhoea when the whole skin is rubbed or heated. A simple experiment to show that after the subsidence of infection there is some change in vessels is found in the warming of the skin of a person who has just recovered from impetigo: the areas are shown up as of deeper erythema mapped out on the unaffected skin.

E. *Nervous Stimulation.*—After the complete disappearance of all signs of the eruption of herpes zoster in a young man, areas where lesions had been present were found to remain excessively active in their response to heat stimulation. Urticarial papules may reappear frequently at one point of the body, and the mildest of external or internal stimulation may be sufficient to cause whealing—for example, a mosquito bite on the hand of a middle-aged medical man left such a sensibility for at least eight years; the least provocation, such as temporary ill health or overwork, will cause the lesion to become irritable and raised. Darwin has noticed that blushing will occur in areas which are the subject of constant thought. He quotes the example of a pianist with rather ungainly hands who blushed from the mid-forearm downwards whenever hands were mentioned or even when he thought of them. Blushing can certainly become a vascular habit.

F. Light Stimulation.—In Finsen's original experiments on the effect of light on the skin he noted that even after six months' absence from stimulation by light the areas when rubbed showed an increased response to stimulation. This phenomenon is often seen in those who have been sunburnt and who have returned to normal colour. Heat, mechanical, and even emotional stimuli may be sufficient to cause the reappearance of the erythema originally produced by the light.

Conclusion.

It should be realized that continuous dilatation of capillaries and arterioles if persisted in will produce a paralysis of vessel wall, for all contractility to cold and mechanical stimulation has been lost. The acquisition of healthy vascular habit on the part of the blood vessels of the skin which are liable to lose tone or capacity for response is made use of in the alternate hot and cold douching employed in the treatment of pernio. There is an experimental basis for such treatment, and especially so if pernio be regarded as merely an exaggerated physiological response in an unbalanced individual.

The most important conclusion to be drawn from the above remarks is that vessels can acquire a "bad habit." We have a rational basis for regarding relapses in certain forms of skin trouble as being due to a non-specific sensitization. This is of marked legal significance when considering capacity for work of persons who have suffered from "trade" dermatitis.

MEDICAL, SURGICAL, OBSTETRICAL.

INTERMUSCULAR LIPOMA OF THE CALF.

A LIPOMA may take origin from almost any structure in the body, but an interesting example may yet be sufficient to arrest the attention of readers.

A married lady, aged 41, for eleven years had watched the progressive increase in the circumference of the calf of the right leg; her anxiety increased in direct proportion to the rate of fashionable change in the length of ladies' skirts, though the limb was not rendered unsightly or misshapen; apart from an obvious diffuse enlargement of the calf the contour of the limb remained that of the normal one. The greatest circumference of the affected limb exceeded by six inches that of the opposite.

Lipoma, one-third actual size

Pain and stiffness on movement were entirely absent. Elevation of the limb did not decrease the swelling, but it hardened with contraction of the calf muscles, indicating that it either involved the muscles themselves or was covered by those structures. There was increased resiliency in the affected calf as compared with the other. X-ray examination showed no bone changes, but the outline of the tumour was distinctly seen. With the provisional diagnosis of lipoma, operation was advised.

Through a curved incision on the medial aspect of the calf the gastrocnemius and soleus muscles were displaced laterally and a large lipoma was revealed lying between the superficial and deep groups of muscles; its pedicle arose from the interosseous membrane. The tumour after removal measured 7 by 5 inches and weighed 1¾ lb. It had been moulded, presumably by the tension and action of the muscles, so as to preserve to perfection the normal configuration of the calf.

The patient made an uninterrupted recovery; but the circumference of the affected limb was still one inch more than that of the normal one, due most probably to two factors—oedema and hypertrophy of the muscles.

I have to express my indebtedness to Professor E. W. Hey Groves for permitting me to publish this case.

Assistant to the Professor of Surgery, Bristol University, and Surgical Registrar, Bristol General Hospital.

CARCINOMA OF THE HEART.

I WOULD like to put on record a case of primary squamous-celled carcinoma of the wall of the left ventricle of the heart.

An old woman, aged 77, was admitted to the Tooting Bec Mental Hospital on August 28th, 1925, and died on December 25th, 1926, after suffering for five to seven days from hypostatic pneumonia. She was a typical case of senile dementia and ran a very common course for that condition. The heart was not suspected, but at the *post-mortem* examination a large white tumour, about the size of a hen's egg, was found in the anterior wall of the left ventricle. The whole of the alimentary tract was searched for a primary lesion, and a suspicious piece of lung and of cervix uteri were sent with the tumour to the Metropolitan Asylums Board research and pathological services. The pathologist reported that the heart tumour was a typical squamous-celled carcinoma; the cervix afforded no evidence of any tumour, and the lung presented some bronchopneumonia. To the naked eye the tumour showed some degeneration towards the centre.

London, S.W. THOMAS LINDSAY, M.D., F.R.C.S.Ed.

APPENDICULAR COLIC ASSOCIATED WITH TUBERCULOUS PERITONITIS SIMULATING ACUTE APPENDICITIS.

THE following unusual case seems of sufficient interest to merit publication.

A lad, aged 13, when admitted to the Booth Hall Infirmary, Manchester, had for twenty-four hours complained of severe abdominal pain. The onset was sudden; at first it was over the navel, but later it settled in the right side above the groin. He had vomited several times, and the bowels had not acted for two days. There was no history of a similar attack. He had been coughing for several days. The abdomen was rigid and tender, the tenderness being most marked in the right iliac fossa; McBurney's point was hyperaesthetic. The temperature was 101.2° F., the pulse was 104, regular and full, and the respirations 18. A simple enema was given, and the return contained a trace of faeces; no flatus was passed. Digital examination of the rectum showed considerable tenderness on both sides of the pelvis.—A diagnosis of acute appendicitis was made, and it was decided to operate. Ether was given by Pinson's bomb. A right para-median incision was made, the rectus muscle being pulled outwards instead of inwards. The peritoneum contained a small quantity of fluid. The appendix appeared to be quite healthy, but the mesentery was studded with tuberculous glands of rather recent origin. I removed the appendix and closed the abdomen. The lumen of the appendix was filled with threadworms.

The patient made an uninterrupted recovery from the operation, but a little later he complained of severe abdominal pain. Masses of enlarged glands were palpable in the abdomen. The temperature was hectic and the bowels costive. He began to vomit after meals, but I came to the conclusion that the pain and vomiting were due mainly to a neurosis. Suggestion was first tried as a cure, with only partial success; but the vomiting ceased entirely, and the pain became much easier after the patient had been shown and told the use of a stomach-tube.

Several months in bed on a balcony facing a large park, together with daily treatment with the tungsten arc lamp, have been beneficial; but the mesenteric glands have greatly decreased and his general condition greatly improved since the exhibition of tuberculin emulsion. He was sent to a sanatorium to complete the cure.

No threadworms were detected in his stools while he was in the infirmary.

Booth Hall Infirmary, Manchester. GERALD RALSTON, M.R.C.S., L.R.C.P.

MENINGITIS AS A COMPLICATION OF PREGNANCY.

MENINGITIS in pregnancy is said to be rare, but it seems to occur often enough to merit consideration in the differential diagnosis of eclampsia. During the last twelve months I have treated the following cases in the North Evington Infirmary, Leicester; both present points of interest.

CASE I.

Mrs. S., multipara, aged 26, whose previous health had been good, complained of a very severe headache for a week previous to admission, and, on the evening before admission, a commencing left-sided facial palsy was noticed by her doctor.

Examination showed that she was full-time pregnant, but not in labour. The pupils were dilated and the reaction to light was lost. There was slight but definite paresis of the left side of the face and some loss of power in the left arm. No classical signs of meningitis were present. The temperature was 102.6° F., respirations 44, pulse 124. A catheter specimen of urine measuring 18 oz. was acid, high coloured ("febrile"), and contained a faint trace of albumin. On lumbar puncture the cerebro-spinal fluid was seen to be very cloudy, and bacteriological examination showed the presence of the pneumococcus in pure culture.

Five hours after admission the condition was obviously hopeless. Quinine was administered, the os dilated manually, and a live

infant was extracted by high forceps. The mother died five hours later.

At the *post-mortem* examination the surface of the cerebrum was covered by thick, greenish pus. The pleurae, at both apices, were adherent to the chest wall, and the lungs were congested, but there was no consolidation or cavitation.

The infant lived for several weeks, and died of acute enteritis.

CASE II.

Mrs. E., multipara, aged 36, was admitted with a history of otorrhoea of several years' duration. She was seven months advanced in pregnancy. She had enjoyed normal health until five hours before admission, when she had two "fits" and became comatose and delirious. Her family doctor considered she was suffering from eclampsia, while another practitioner diagnosed the case as "mental."

On examination the temperature was 99.6° F., falling to 96° F., respirations 32, pulse 110, irregular. She was restless and noisy. The pupils were unequal and reacted to light; the reflexes unchanged, and marked retraction of the neck developed later on. The urine contained no abnormal constituent, and 41 oz. were passed in two days. There was a discharge from the *right* ear. On lumbar puncture the cerebro-spinal fluid was found to be purulent and was so thick that it could only drop slowly from the needle.

The patient died thirty-six hours after admission. Caesarean section was performed three minutes after death was certain, and a live foetus weighing 4 lb. was extracted.

At the *post-mortem* examination the lower surface of the cerebellum and medulla and pons and the surface of the temporo-sphenoidal lobe and insula were covered by a thick layer of greenish pus. The source of infection was the left middle ear, by way of the tegmen tympani. Part of the temporo-sphenoidal lobe appeared to be eroded, but there were no signs of a definite cerebral abscess. The causal organism was the pneumococcus.

Meningitis in pregnancy is most likely to be confused with eclampsia, which it may greatly resemble. The differential diagnosis is easy; examination of the urine and lumbar puncture clear the matter up. *Post-mortem* Caesarean section is so easy to perform that it needs no description and can hardly be dignified by the term "operation." It should be performed as soon as possible after death is certain. Care is necessary to avoid injury to the foetus, and the operation need not be unduly hurried.

I am indebted to Dr. E. C. Hadley, medical superintendent, for permission to publish these notes.

CLINICAL AND SCIENTIFIC PROCEEDINGS.

SOUTH WALES AND MONMOUTHSHIRE BRANCH.

Stillbirths and Neo-natal Mortality.

THE winter meeting of the South Wales and Monmouthshire Branch was held at the Hotel Metropole, Swansea, on January 27th; in the absence of the President, Dr. R. Prichard, Dr. A. CLARKE BEGG occupied the chair.

Dr. T. EVANS, medical officer of health, Swansea, showed a chart of the number of children who died in Swansea each year during the thirty-five years ending 1925, arranged in averages of five years. During the first three periods the mortality rate had remained at approximately the same level, but between 1905 and 1909 this rate began to drop, and had continued to do so since. For the five-year period 1910-14 and afterwards the table was more instructive, as all stillborn infants became notifiable under the Notification of Births Act, 1908, and the death rate for children under one week of age could be included. These figures showed that no reduction had been made in the "stillbirth rate" during this fifteen-year period, and the rate for 1925 was even higher. The same held true for the "death rate under one week." On the other hand, the death rate in infants "over one week and under one year" showed a marked reduction, the 1925 figure (43) being well under half the average (96) for the 1910-14 period. Alongside the official infant mortality rates calculated on the number of living births, he showed what he called a "true infant mortality rate," including amongst the deaths the "dead births," and calculating the rate on both living and dead births combined. The beginning of the reduction of the official infant mortality rate coincided with the time of the appointment of the first superintendent of midwives and health visitor in 1904, and Dr. Evans considered that the education of mothers in infant care had been an important factor in the improvement. A table was shown compiled from inquiries made by the superintendent of midwives of the circumstances associated with 414 full-time, successive stillbirths in the town of Swansea. These circumstances had been classified in accordance with the classification of causes of death in the recent report of the Medical Research Council.

The classification of the causes in the table and the report was not strictly comparable, as in some of the Swansea cases instrumental delivery had been taken as the chief circumstance and they had been included under this heading, whereas they might possibly be more appropriately included under another, such as ante-partum haemorrhage. There was no classification in the Swansea cases under "placental state" as the superintendent of midwives could not make inquiries as to placental conditions. It was shown that 59 per cent. of the full-time stillbirths of Swansea were associated with instrumental delivery. There was a marked contrast between the Swansea figure for the neo-natal deaths under prematurity and that of the Medical Research Council, but this might be partly explained by the higher percentage in the latter report under "complications of labour." In conclusion Dr. Evans quoted an extract from the Medical Research Council's report advocating the practice of preventive midwifery as a means of reducing dead births and neo-natal deaths.

Treatment of Eclampsia in General Practice.

Dr. CELLAN JONES read a paper on the treatment of eclampsia in general practice, some of the observations being based on the result of six months' research work in Vienna. He said that eclampsia was a term used even in the time of Hippocrates, but unfortunately the early writers frequently confused true eclampsia with epilepsy complicating pregnancy, the two conditions being regarded as identical. In 1713, however, Amberg gave a report of a case which might be regarded as genuine. Reading critically through the literature of later times, several régimes of treatment were definable, each with its firm adherents. At the time when blood-letting was fashionable it was naturally applied to every case of eclampsia, and undoubtedly cured some cases which would otherwise have proved fatal. With the discovery of chloroform as an anaesthetic in complicated obstetrics its application for the control of convulsions in pregnancy naturally followed. It was only within the last half-century that surgery had made its most important strides, recovery after operation becoming the rule rather than the exception. Since also the obstetrician laid the blame for eclampsia entirely upon the foetus, the surgeon was encouraged in a third routine measure—the surgical treatment of eclampsia. This was the period of rapid Caesarean section, vaginal Caesarean section, and accouchement forcé in all its horrible branches. In the treatment of the pre-eclamptic state Dr. Jones said that he had adopted the Rotunda method almost in its entirety. The method was good, and had been responsible for a very considerable reduction in the mortality. The treatment adopted for the eclamptic state must be that which was least exhausting to a comatose patient with rapidly recurring and dangerous convulsions. Narcotics, usually in heroic doses, had been used for many years before Stroganoff of Petrograd employed them in a routine carefully regulated both as regards dosage and time of administration. He used morphine and chloral hydrate, and attached great importance to segregation in a quiet, darkened room, with avoidance of all forms of irritation. Generally speaking, Dr. Jones did not believe in venesection, and was opposed to all forms of interference with pregnancy. There were two fairly easily definable types of albuminuria in pregnancy. The first or nephritic type was gradual in onset; oedema was more often extensive, but there was little or no rise in blood pressure. There was little tendency to the onset of convulsions, but recovery was slow, and there was nearly always some permanent damage to renal function. In the second, or true pre-eclamptic, variety there was a much shorter history, and oedema might be trifling, but the blood pressure was almost always raised, and without treatment convulsions followed almost inevitably; should recovery occur there was seldom any permanent damage to

the kidneys. Other premonitory signs must be looked for, including the swollen face and puffiness affecting the hands, the lower abdomen, or the vulva. Headache, vomiting, drowsiness, and disturbances of vision were danger signals, and there should be no delay in the commencement of drastic treatment. The pre-eclamptic patient should be confined to bed as soon as her condition was discovered, and three ounces of mist. sennae co., with one drachm of magnesium sulphate to each ounce, should be given every eight hours. No food was allowed, but if vomiting occurred water or weak tea was permissible. The urine was collected and twenty-four-hour specimens measured. Large fluid consumption with purgatives must be continued until over forty ounces of urine were passed on two consecutive days. All being well it was then possible to begin with milk, leading up to milk puddings, fish, and other light diet. Unfortunately a large number of these cases were not seen in time; 20 per cent. occurred during labour, when the prognosis was least serious. The 60 per cent. beginning between the fifth month of pregnancy and term were more alarming, but most fatal of all were the 20 per cent. which began after labour was terminated. Morphine was given in sufficient doses to keep the patient moderately narcotized throughout its exhibition. Magnesium sulphate, by its synergistic action, enhanced the sedative effect of the comparatively small doses of morphine. Luminal had replaced chloral hydrate for two reasons: it was not a cardiac depressant like chloral, and it had in addition a specific dilating effect on the vessels of the brain. Venesection was recommended in practically every case where the blood pressure exceeded 140 mm. of mercury, and even this stipulation might be disregarded when the rectal temperature was high and the convulsions were frequent. A most dangerous preparation to use in eclampsia was pituitrin. With regard to labour complicating eclampsia, it was most important to realize that recovery varied inversely with manipulation. If the cervix was not dilated manual dilatation should never be employed, and version was contraindicated unless delivery was impossible without t. Forceps were permissible only to shorten the second tage, when the cervix was fully dilated and the presenting art almost on the perineum. Tables were shown giving e mortality (1) where delivery was natural, (2) when minor manipulations were used, and (3) in cases where forceps, Caesarean section, or accouchement forcé were adopted. Treatment of the convalescent stage was discussed and case histories mentioned in conclusion.

Partial Gastrectomy.

Mr. H. W. GABE demonstrated two cases in which partial gastrectomy had been performed for chronic gastric ulcer with success.

(1) A man, aged 41, had a history of ten years' abdominal discomfort, coming on about two and a half hours after food. Vomiting was frequent and relieved the pain; the vomit was of a brownish colour but never bright red. On occasions the pain was relieved by taking food. The periodicity of the attacks had been well marked, and dieting had no real relief. Constipation of the stools for occult blood had been gradual. Examination was noted, and loss of weight had been positive. The Wassermann reaction was negative, and the *x*-ray report stated that there was delay in the emptying of the stomach, with a penetrating ulcer on the lesser curvature near the pylorus. In spite of a Hurst diet and the administration of atropine, the patient lost weight steadily. Operation by Moynihan's method of partial gastrectomy was performed and an ulcer the size of a sixpenny piece was found present on the lesser curvature, near the pylorus, and adherent to the pancreas. Microscopical section showed it to be benign, with much fibrosis. For the last fifteen months since operation the patient had followed his work as an engine driver with regularity. The abdominal symptoms had disappeared entirely and his weight had increased from 8 st. 2 lb. on admission to 11 st. 4 lb. in January this year.

(2) A woman aged 40. She had had her first attack of indigestion sixteen years previously, with pain immediately after meals. The symptoms had recurred with regularity. Alkalis at first relieved the pain, and the appetite was good. The patient was much wasted, with a scaphoid abdomen; there was no local tenderness nor rigidity, and no tumour was felt. A test-meal analysis showed gastric function to be mainly of the normal type; there was rather prolonged secretion with some degree of hyperacidity, and the result was compatible with gastric ulcer. With a barium meal an hour-glass stomach was found; the stricture dividing the stomach was placed about midway between the cardiac and pyloric orifices. There was also definite scarring of the anterior wall of the first part of the duodenum. An operation by Moynihan's method of partial gastrectomy was performed, the distal pouch of the stomach and the appendix being removed. About nine small ulcers were seen in the specimen of the stomach. The ulceration appeared to be confined to the mucous membrane, and section of the ulcer showed a subacute form of inflammation between the gastric gland acini. There was no evidence of malignancy. The patient was now on ordinary diet, suffered no discomfort, and was putting on weight steadily.

Mr. H. E. QUICK gave a demonstration of the slit-lamp associated with the names of Gullstrand and Vogt. This apparatus was primarily an instrument combining brilliant critical illumination of the tissues of the living eye, with a binocular microscope.

Reports of Societies.

RENAL HAEMATURIA.

AT a meeting of the Section of Surgery of the Royal Academy of Medicine in Ireland, on January 14th, with the President, Mr. ANDREW FULLERTON, in the chair, Sir ARTHUR BALL read a paper on renal haematuria.

Sir Arthur Ball first commented on the serious import of this symptom, and then gave an account of the difficulties frequently met with in diagnosis; he showed how serious the result might be when there was delay in exploring a kidney which had been proved to be the source of the haemorrhage. This was illustrated by the notes of five cases. The function of the other kidney, and the total power of excretion, should be estimated previously, so that, if necessary, nephrectomy could be performed without hesitation. Details were then given of three cases in which the kidney was found apparently normal when exposed for haemorrhage, and the paper concluded with a brief review of the hypothesis as to the origin of "adrenal rests" and tumours of the kidney.

Mr. A. A. MCCONNELL emphasized the importance of examining a patient by cystoscope during the actual time of the haematuria. The first attack of haematuria might be separated by months or even years from the second attack, and therefore every patient should be examined by cystoscope during the first attack. Sometimes patients suffered from two attacks without any attempt at diagnosis being made, and when they were finally admitted to hospital the condition was found to be inoperable. He referred to the difficulty of finding the source of the haematuria in some cases, but thought that if it was impossible to make a diagnosis of a kidney lesion before the operation he did not think it was possible to make it while operating.

Sir W. I. DE C. WHEELER said that it must not be forgotten that ligaturing the ureter in cases where nephrectomy was impossible or hazardous might be the operation of choice. He had had one case when nephrectomy was attempted by a surgeon of great experience and skill in this branch of surgery, but had to be abandoned, owing to difficulties arising from previous operations and the onset of uncontrollable haemorrhage. The patient was passing blood and pus in large quantities, associated with the presence of calculi. The calculi were curetted out of the kidney bed, and the ureter was divided and ligatured by the extraperitoneal route through a ventral incision. The patient recovered. Sir William Wheeler recalled two consecutive cases of haemorrhage from the kidney from rare causes. In the first case there were four stones in the upper pole and ten in the lower pole of the kidney. After nephrectomy a tumour was found, which, on microscopic section, proved to be squamous-celled carcinoma. A series of sections demonstrated the transition from pelvic to squamous epithelium, with the addition of squamous cells embedded in dense fibrous tissue in the capsular area. Infiltrating strands of squamous epithelium with "pearl" formation were present among the glomeruli and tubules. Squamous-celled carcinoma of the kidney was very rare. In the great majority of published cases calculi were also present.

In the second case the haemorrhage from the kidney came on suddenly and in greater profusion: life was only maintained by transfusion of blood. Cystoscopic examinations were made without result owing to the continuity of the bleeding. The haemorrhage finally ceased, but on

palpating the left renal region it recurred and a nephrectomy was at once performed. On examination of the specimen an angiomatous tumour was discovered, which took the form of proliferation of small blood vessels forming a rich arterial plexus At the upper end of the pelvis a plexiform mass of thick-walled vessels was observed occupying an area of about 1.5 centimetres in diameter. Other cases had been recorded, but angiomata of the kidney were extremely rare.

Mr. V. J. MCALLISTER said that congenital polycystic kidney must be remembered as a cause of haematuria. The cysto-urethroscope was sometimes useful in discovering the source of bleeding. He referred to a case which he had recently seen with a long history of urinary trouble and severe bleeding; it was found at operation that the kidney had been very largely destroyed as a result of chronic inflammatory change. He also mentioned the case of a young man who suffered from very severe pain and haemorrhage from one kidney; the cortex was incised and found normal. The kidney was then removed, when hydronephrosis was found and microus haemorrhages. This would have caused the bleeding, but he did not think it could have caused the severe pain. When treating a patient in early adult life for haematuria the possibility of tuberculosis should always be borne in mind.

Mr. A. CHANCE referred to chronic interstitial nephritis as a cause of haemorrhage. He had seen a man five years ago with severe recurrent haematuria; cystoscopy showed blood coming freely from the right ureter. The right kidney was exposed, and appeared outwardly to be normal, but owing to the severe haemorrhage it was removed. Later, the patient had haemorrhage from the other side, and during the next year there were four or five attacks of bleeding. He was now in hospital, having been operated on for chronic duodenal ulcer.

Dr. W. M. CROFTON said that if bleeding from the kidneys was caused by tuberculosis he thought it could be cured by immunization. Microbial cultures were very important, and cultures should be made even from urine which contained no pus.

The PRESIDENT called attention to the danger of treating haematuria by medicine. Some tuberculous cases had been treated by tuberculin, but he himself was against this, and thought that haematuria was very difficult to cure except by radical surgical operation. He did not believe that copious haematuria from the kidney was at all a common symptom of tuberculosis. Nearly all his patients had been cystoscoped. In his own series of 600 cases 47 were classified as having essential haematuria; these were cases in which no cause for the haemorrhage from the kidney could be found. There were 44 cases of renal calculus; this could give rise to severe haematuria. There was one case of pyelitis and renal tumour, and some cases of polycystic kidney. In one case of polycystic kidney in which the kidney was removed against his advice the patient died from uraemia. A very small injury to the kidney could produce haematuria. It was useless to attempt to diagnose cases of haematuria without a cystoscopic examination. In cases of tumour of the kidney, even in the early stages, there was generally some distortion of the pelvis, and it was usually possible to diagnose some alteration in the shape of the pelvis or the kidney, apart from the actual filling defect. In cases of ureteral papillomata if with a catheter it was possible to get beyond the level of the small papilloma, and then clear urine was obtained, the inference was that the haematuria was coming from some portion of the ureter. Quite a large number of patients with nephritis had unilateral or bilateral haematuria. The presence of organisms in the urine was not proof of disease. In one of his cases tubercle bacilli had been seen in the urine; he had watched the case for several years to see if tuberculosis would develop, but the patient had remained well.

Sir ARTHUR BALL, in reply, agreed that it was most important in these cases to make an early diagnosis. It was sometimes very difficult to know when a kidney should be removed, and, though it was a grave responsibility to remove an apparently healthy kidney, still, in some cases, delay due to inconclusive evidence was disastrous.

Ectopia Vesicae.

Mr. W. C. STEVENSON showed a treated case of ectopia vesicae in a boy aged 10. Mr. Stevenson said that he had transplanted first the right ureter into the rectum on February 26th, 1926, and the left on June 29th, the bladder being removed on November 16th. The ureters traversed the rectal wall between a longitudinal muscular band and the mucous membrane for an inch, following the technique described in the Mayo Clinic. A tube was left in the rectum for six days after each transplantation. The boy had good control of his rectum, but sometimes wet the bed at night.

Mr. A. CHANCE said that this operation, in his mind, had a series of merits which put it above all other operations for the condition. It was technically easy to deal with one ureter at a time, and it was safer than to operate on both together. The risk of infection of the kidneys was reduced to a minimum by the valvular method of inserting the ureters into the pelvic colon.

Mr. V. J. MCALLISTER referred to an operation which had been praised by Professor Young of Baltimore for ectopia vesicae. The bladder was approached from the perineum, an incision was made to expose the perineal tissues, the central point of the perineum was divided, and it was then easy to get to the base of the bladder. In this way the bladder could be drawn right down into the pelvis.

Sir ARTHUR BALL had only operated on one case of ectopia vesicae, and that was nineteen years previously. He had transplanted both ureters at the same time, and the result had been very satisfactory. The patient (a man) was now perfectly well, and able to earn his own living. It was questionable whether it was safer to operate on one ureter first or to treat both simultaneously. He had seen several patients with this condition since the one he had operated on, but they had all died before they were in a fit condition for operation.

The PRESIDENT, referring to Coffey's operation, said he did not think it was advisable to operate on both ureters at the same time. In adults operations on the urinary organs were never contemplated until renal function tests had been made. These tests, however, were not used for children, and he thought they ought to be. One child upon whom he had operated had died of uraemia about thirteen days after the operation. One of the kidneys was enlarged.

Sir WILLIAM WHEELER said that he thought the result in the case of ectopia vesicae was very satisfactory. He had under observation a little boy, aged 10, who had been so well nursed that cleanliness was complete, and the everted wall of the bladder was not inflamed; there was no ulceration, and the urine was not ammoniacal. He thought that all attempts at plastic operations should now be abandoned, and that the transplantation of the ureters should be recommended as a routine. The prognosis was far better if the urinary flow was diverted into the rectum by modern methods than if the patient was left alone. Ascending infection occurred in the great majority of unoperated cases before adult life. Coffey had sent him a description of his operation, and the new technique appeared simple and safe. He did not agree, however, that this improved technique justified transplantation of both ureters at the same time.

Massive Gangrene in Youth.

Mr. STEVENSON showed also a case of amputation of the arm for dry gangrene in a girl, aged 22, following abscesses in the tonsils and an acute septic condition of the left side of the neck and shoulder. The patient had been sent for radium treatment of the subclavian area with a view to improving the condition of the arm, which was pulseless owing to the blocking of the subclavian artery, presumably by a septic clot. She had been given an autogenous vaccine. A pad containing radium was applied over the subclavian, and a smaller one in the axilla for three hours. The fingers were gangrenous on admission when the radium was applied, and a line of demarcation formed in the middle of the forearm within twenty-four hours of its application. The arm was amputated two days later, eight days from the onset of the subclavian trouble. A circular amputation of the forearm was abandoned, as there was no

sign of bleeding. A small artery spouted feebly for an instant at the back of the arm when the muscles were severed above the elbow. There was no other bleeding except a slight ooze from the medullary cavity of the humerus when it was divided about the centre of the arm. A tourniquet was not employed, and no vessel was ligatured. As the muscles appeared healthy, the stump was closed by suture, leaving in a large drainage tube to avoid tension and as a precaution in case of sepsis, which, fortunately, did not occur. No tight bandages were applied, and the stump was kept warm for a fortnight with the aid of a carbon filament electric lamp. The stitches were removed after a fortnight. As the wound at the end of the stump was sluggish and appeared bloodless on the eighth day, the end of the stump was radiated for six hours, and the subclavian area and the axilla for nine hours. The stump was completely healed three weeks later.

Dr. CROFTON said that when he saw the patient she was extremely ill. Her arm was very swollen, pus was pouring from the left tonsil, and she had a severe headache. The heart sounds were quite clear and the pulse was traceable, though in the axilla there was no pulsation. He gave her antigen. Next day she was better, but there was still no pulsation in the arm, and he thought it was possibly a case of thrombosis, and sent her into hospital.

Mr. R. C. B. MAUNSELL commented on the rarity of massive gangrene in a young person with the arteries apparently healthy. He thought this must be a thrombosis which accompanied an acute bacterinl disease; he would hardly call it a septic thrombosis, but thought it would be wiser to call it an infective condition. He had seen a similar occurrence during a case of acute osteomyelitis. Rendle Short had stated that during the four years he had had three or four cases of gangrene of the arm following pneumonia, and Mr. Maunsell thought that the present case was almost identical with those of Rendle Short. He did not think that such a case of most sudden massive gangrene should be termed dry gangrene, but that it should be included in the moist gangrene class. He did not agree that radium could have done anything for a condition like this. Rendle Short had brought out another point—namely, the type of case in which embolectomy should be done. Mr. Maunsell had tried embolectomy in one case, but owing to extensive clotting in the distal arteries no benefit to the patient had followed.

Sir WILLIAM WHEELER pointed out that obstruction to one of the main arteries in the course of infective diseases was not very uncommon. Rendle Short had drawn attention to thrombosis of the arm following pneumonia, and described an unsuccessful case of embolectomy. One case had been reported of a child under three years of age in whom both legs became gangrenous during an attack of scarlatina. Blockage of arteries also occurred in typhoid, typhus, and other fevers. Recent results of embolectomy were most encouraging. In cases where the artery was inaccessible, such as at the bifurcation of the aorta, the embolus could be teased out by opening the external iliac arteries or upper portion of the femoral. According to Jefferson, fifteen successes had been obtained in twenty-eight cases since 1922. There was no more urgent operation in surgery than blockage of a main artery, except the control of haemorrhage, and it must be performed at once if success was to be expected. The question of how long the blood stream through the deep arteries to an extremity could be suspended by an embolus was of great importance, but had never been accurately estimated. Sir William Wheeler mentioned a very successful case of embolectomy recently reported by Jefferson. The embolus was situated at the origin of the superior profunda artery of the left arm. The clot was removed through a longitudinal incision under local anaesthesia, and the relief afforded was immediate and dramatic, the arm completely recovering. The lesson was that a limb could be saved when gangrene was impending, if operative treatment was not delayed.

Mr. STEVENSON, in reply, said that the specimen now did not resemble a dry gangrene, but when he had first seen the patient her fingers were black and quite dry, the whole arm was discoloured, and it looked as if it would have become quite dry.

Traumatic Dislocation of Hip.

Mr. R. A. STONEY showed skiagrams of a case of traumatic dislocation of the hip in a child, a boy of 6, who, while crossing a road, had been run over by a motor car; when picked up he was lying between the two wheels, the front wheel having gone over him. The head of the bone was out of position. An anaesthetic was given, and the dislocation was reduced by full flexion, abduction, eversion, and full extension. The head of the bone went into position, and on the third day the child was allowed to move his leg freely; on the seventh day he was allowed out of bed, and on the eighth day he left hospital, able to walk.

Mr. W. DOOLIN mentioned a somewhat similar case of traumatic dislocation in which the posterior margin of the acetabulum was broken off. This patient, however, was not fit to be discharged from hospital for about five weeks.

Mr. H. STOKES referred to a patient with a dislocated hip whom he had treated in hospital, and who had had the condition for eight weeks. In all textbooks it was agreed that it was impossible to get a hip in after a month, but he had had no difficulty in getting in this patient's hip with ordinary manipulations.

TREATMENT OF RINGWORM BY THALLIUM ACETATE.

AT a meeting of the Section of Medicine of the Royal Academy of Medicine in Ireland on January 28th, the President, Dr. G. E. NESBITT, in the chair, Dr. MAURICE DRUMMOND showed three cases of ringworm in children, aged respectively 6, 4, and 2 years and 5 months, which had been epilated by the internal administration of thallium acetate.

Dr. Drummond said that the method had been used successfully in over 500 cases by Cicero and Peter in ringworm schools in Mexico, and in over 100 cases by Buschke and Langer in the Rudolf Virchow Hospital, Berlin. He gave a short account of the experimental and clinical methods by which these investigators had made this form of epilation practicable and safe. It was essential that the protoxide of the acetate of thallium should be used; he had employed the preparation of Kahlbaum. The Germans had found that 8 milligrams per kilogram of body weight was the most satisfactory dose for children of all ages. Peter in Mexico gave 5 milligrams per kilogram for children under 5 years. In each of the children shown 8 milligrams had been administered. Dr. Drummond had found it only just sufficient in the case of the two younger children. Rapid and profuse fall of the 2 oz. of sweetened water. The drug was given in hair occurred on the fifteenth day with the two younger children. The fall had not been so satisfactory with the eldest child. The action of the drug was apparently selective, the eyebrows and fringe on the front of the head being unaffected. Since x-ray epilation could not be performed in children under 3, he thought that thallium epilation should be of much value in such young children and in epidemics. The eldest child's hair was growing again well after epilation in November, and was beginning to grow in the case of the second child, who had been treated in December. The youngest child had only just been epilated. The drug was contraindicated in the presence of albuminuria. In case of partial failure a further dose must on no account be given within at least two or three months, as the action of the drug was strongly cumulative, and symptoms of acute poisoning might develop. The greatest care was necessary in the weighing of the child and of the drug. Dr. Drummond was not yet sure that a slightly higher dose might not be necessary with older children. The constitution, the climate, and the freshness of the drug were all factors to be considered. The PRESIDENT said that the effects of the treatment in the three cases shown were very striking. He regarded the method as much better than x rays, but further experience would be necessary before a final judgement could be pronounced.

Dr. E. FREEMAN referred to a statement in the *British Journal of Dermatology*, in which it was reported that

104 cases of ringworm had been treated successfully by this method; in all of them the hair had grown again.

Dr. W. G. HARVEY referred to the original experiments with thallium by Sabouraud, which had been quite unsuccessful; the very large doses employed had perhaps been the cause of the failure, since very serious symptoms had arisen after treatment, such as haemorrhage and purpura. This method now seemed to be of much use, quite apart from the question whether it would replace *x*-ray treatment. The difficulty of *x*-raying young children was great.

Dr. DRUMMOND, replying, said that Langer in Berlin had stated that they only obtained the thallium salt from one chemist, and that the drug deteriorated with age. If the drug was fresh the hair would fall out on the fifteenth day after application, but if the drugs were not fresh when applied the hair might take three weeks to fall out.

Spontaneous Cerebral Haemorrhage.

Dr. V. M. SYNGE showed specimens from a case of spontaneous haemorrhage into the brain of a man, aged 21, who while at work fell down unconscious. He had been perfectly healthy previously, and had received no injury of any sort.

When admitted to hospital a few hours later he was still unconscious, the limbs were rigid and flexed, and occasional clonic spasms occurred. The neck was stiff. The pulse was 66, the temperature 99° F., and the respirations 26. He vomited undigested food several times. A catheter specimen of urine contained a fair amount of albumin. The blood pressure was normal, and the blood urea was 65 mg. per 100 c.cm. During the following days the temperature rose to 104° F.; the unconsciousness diminished. Two days after the attack 30 c.cm. of cerebro-spinal fluid was removed by lumbar puncture; it was under great tension, and contained much blood. There was no improvement after the puncture. The blood Wassermann reaction was negative. The patient remained semi-conscious, the neck stiffness increased, Kernig's sign was positive, and the limbs were stiff but without paralysis. Five days later another lumbar puncture was performed, and 35 c.cm. of fluid under tension was removed. A little blood was present, but the fluid was otherwise clear; the globulin was slightly increased, glucose was present, there was no pus, the fluid was sterile on culture, and no tubercle bacilli were found. An intravenous injection of sodium salicylate solution was given, the high temperature, general condition, Kernig's sign, and the characters of the cerebro-spinal fluid suggesting the probability of encephalitis lethargica. The temperature dropped, the pulse, which had been 100, fell to 60, but there was no improvement in the general condition. The fundus of each eye was normal. The patient became suddenly convulsed, he collapsed ten days later, and died in a few hours. At necropsy there was no sign of any injury. In the anterior horn of the right lateral ventricle there was a mass of clotted blood which had destroyed a large part of the frontal lobe; all the ventricles were full of blood, and there was a mass of effused blood on the base of the brain. The heart, spleen, kidneys, and other organs were normal, and there was no sign of arterial disease. Sections failed to show any evidence of a tumour in the brain, and the kidneys were normal.

This apparently quite spontaneous haemorrhage had evidently originated in the right frontal lobe, burst into the ventricles, and thence into the subarachnoid space.

The PRESIDENT said that in so young a patient no one would have thought of making a diagnosis of cerebral haemorrhage, especially in the absence of the phenomena which were usually expected. The cause of spontaneous haemorrhage was always difficult to ascertain. It was possible to have fairly advanced renal disease with a blood urea figure no higher than 65, and he thought that in this case the boy probably had some chronic renal disease. The earliest incidence of cerebral haemorrhage that he could remember had been in a woman aged 29.

Sir JAMES CRAIG said that although in this case the blood urea was greater than normal, yet the kidneys were healthy. He did not think that it could be assumed that the haemorrhage was due to any kidney disease.

Dr. SYNGE, replying, said it had not been possible to examine the artery which had actually ruptured, on account of the destruction caused by the haemorrhage. The small arteries seen under the microscope appeared to be perfectly normal, and he did not think that an artery was likely to rupture unless the pressure inside was very great. Nothing abnormal had been found in the kidneys, and there had been no evidence of nephritis, except albuminuria, which had been present at first. It was, however, very hard to examine the urine, as the patient had suffered from persistent incontinence.

VERTIGO.

AT a meeting of the Manchester Medical Society on February 2nd, Dr. A. A. MUMFORD in the chair, a discussion on vertigo was opened by Dr. R. I. POSTON.

Dr. Poston dealt with the occurrence of vertigo in epidemic encephalitis or encephalitis lethargica, where this symptom was often associated with other signs of vestibular disorder. Recalling Gertier's "paralysing vertigo" of 1888, he then proceeded to describe "kubisagari," the endemic paralytic vertigo of Japan. Both disorders had much in common, and there could be little doubt that both were variants of the same condition, being due to an infective encephalitis. Dr. Poston suggested that as kubisagari occurred in Japan up to 1912, it was possible that this endemic, or undiagnosed cases of Gertier's disease in Europe, might have been responsible for the pandemic of the last decade. Cases of encephalitis with vestibular symptoms were next described, special reference being made to an outbreak in Strasbourg in 1921. Having dealt with the known pathology of the condition and the results of several experimental workers who actually found vestibular lesions in rabbits, a brief description was given of six cases of encephalitis under the speaker's own care. The vestibular reaction of these cases had been determined and abnormal induced nystagmus had been found in three. One case with complete external ophthalmoplegia was described; simple syringing of the ears with cold water had relieved ptosis, and enabled the patient to move his eyeballs in every direction, alleviating the diplopia of which the patient had complained. In the case of another patient who showed "spasmodic cramp of the upward glance," change of position altered the direction but not the character of the phenomenon. The Babinski-Weil reactions were described, each being illustrated by lantern slides showing the results in nine normal people and ten encephalitic patients. Discussing the diagnosis of vestibular encephalitis, Dr. Poston urged the importance of first excluding cerebro-spinal syphilis, ear disease, and intracranial lesions. It was stated that cases of epidemic encephalitis had occurred with gross signs of cerebellar involvement, yet at necropsy the cerebellum had been found to be normal. Nystagmus might suggest disseminated sclerosis unless definite and incontestable signs of Parkinsonism were present. The following triad was suggested as clinical evidence of disordered vestibular function in the absence of ear disease: disorders of equilibration such as vertigo, spontaneous nystagmus, and abnormal induced nystagmus or abnormal Babinski-Weil reactions. Dr. Poston offered a classification of epidemic encephalitis as follows: (1) vestibular syndrome; (2) juxtavestibular syndrome, with signs pointing to involvement of structures adjacent to or connected with the vestibular nucleus, such as oculomotor symptoms, neuralgia, facial paralysis, dysphagia, sialorrhoea, and disorders of respiration and pulse; (3) pallidal syndrome—namely, tremor and rigidity; (4) striate syndrome, or tremor and myoclonus. Pyrexia and lethargy were the only common symptoms not included in such a classification. The vestibular syndrome in epidemic encephalitis might occur alone or with such symptoms as those mentioned. It might appear at the onset, or during the acute stage of the disease, or it might persist as a residuum, and, lastly, interference with vestibular function might account for many, if not all, of the oculomotor phenomena of the disease.

Mr. DIGGLE, after mentioning that vertigo was only one manifestation of a disturbance of the vestibular apparatus, said that by artificial stimulation of the peripheral sense organ in the labyrinth all the symptoms and signs of such a disturbance—namely, vertigo, nystagmus, reeling gait, and vomiting—could be produced. He further showed that by a close study of such induced symptoms it was possible to test the integrity of the peripheral end organ, the labyrinth, and also, in a few cases, to locate a lesion in other parts of the vestibular nervous arc. Vertigo might be produced by a lesion in the labyrinth, a lesion in its intracranial and spinal connexions, or by ocular lesions. Vertigo arising in acute inflammatory conditions of the middle ear was usually relieved after an efficient para-

centesis tympani. Mr. Diggle drew attention, however, to the prevalence and seriousness of vertigo in acute exacerbations in chronic ear suppuration. The danger lay in the fact that translabyrinthine infection was the commonest precursor of fatal meningitis; the warning signal of vertigo should not be neglected. Vertigo might be due to abnormal pressure of the intralabyrinthine fluids, to irregularities in the vascularity of the organ, or to the effects of toxins upon the nerve end organ. After brief reference to the regulating device of the endolymphatic and perilymphatic membranous tubes of the labyrinth, he suggested that vertigo associated with impacted cerumінous plugs, intermittent Eustachian obstruction, and occasionally hydrops of the middle ear, could be explained by abnormal intralabyrinthine pressure. Increased pressure of cerebro-spinal fluid might directly raise the intralabyrinthine pressure and so produce vertigo, though often cerebral anaemia could not be excluded. He referred to the relief occasionally following lumbar puncture, and to the few cases recorded by Aboulker and Colledge of relief after subtentorial decompression; also to the interesting cases recorded by Mollison of relief in vertigo after trephining the external semicircular canal. In considering vascular lesions affecting the labyrinth, attention was directed to the fact that many patients when examined presented a normal inner ear. Massive haemorrhage as a cause of Ménière's syndrome was considered infrequent, though the occurrence of small leakages from atheromatous vessels he considered could not be denied. Other remote lesions, apart from intralabyrinthine haemorrhage, such as arterio-sclerosis, abnormal blood pressure, certain anaemias, metabolic disorders, and toxins, might be responsible for Ménière's syndrome. Was the vertigo in such cases due to effusions into the labyrinth, to atheromatous disease of the vessels, or to toxic neuritis? Mr. Diggle indicated the analogy in the eye—namely, retinal detachments from effusions, retinal haemorrhages, and amblyopia, nephritic retinal changes. He drew attention to the toxaemic conditions responsible for vertigo, to the frequent association of vertigo with nicotine poisoning and tobacco with nasal sinus suppuration. In discussing treatment he emphasized that no operative ablation of the labyrinth should be undertaken until all other measures had failed, and then only if the labyrinth was functionally inactive.

PUERPERAL SEPSIS.

At a meeting of the North-East London Clinical Society on January 4th, Dr. F. G. CROOKSHANK in the chair, Dr. ARTHUR GILES opened a discussion on the etiology and prevention of puerperal sepsis.

Dr. Giles said that infection from within, as a cause of puerperal sepsis, was relatively uncommon; it might take the form of the waking up of a latent infection in a tube or chronic appendix, caused by the anatomical alterations associated with delivery. Infection from without was the really important matter. In the case of a confinement without either examination or interference, infection could hardly occur, except possibly through a damaged and unrepaired perineum; therefore, the more that confinements were allowed to take their natural course the less was the chance of infection. When intervention was necessary the aseptic precautions adopted should be as complete as for surgical operation, but in many confinement cases this was a counsel of perfection owing to the adverse conditions prevailing. Both objects could be attained in a great measure by a large increase of accommodation for lying-in women in hospitals and maternity homes. With cases collected under one roof each patient could be allowed time for natural delivery, and the lying-in rooms might be fitted and treated like an operating theatre, under which conditions there would probably be a marked fall in the recorded deaths from puerperal sepsis. The ante-natal investigation of every case of pregnancy would give early warning of possible complications, especially in the matter of obstructed delivery, and arrangements could be made accordingly. This was a case in which to be forewarned was to be forearmed, because many obstetrical tragedies were the result of some unfavourable feature whose presence was not known until the confinement was actually in progress.

Dr. KIRKNOFF dealt with the matter from the public health point of view, and detailed a number of cases of puerperal pyrexia notified in his district in recent months. The majority of these cases were due to intercurrent diseases such as influenza, and in one case scarlet fever, and not strictly to be included under the heading of puerperal fever. He described the new arrangements made by the local authority for the supply of consultant advice and hospital accommodation in Tottenham.

Dr. BENIANS continued the discussion from the point of view of the pathologist. The battle between the exogenous and endogenous modes of infection had waged for years, and for the moment an inevitable mortality, ranging from 0.1 per cent. to 0.2 per cent., must be accepted as being inherent at present in the conduct of the puerperium. Without belittling the obviously immense importance of asepsis, prevention and cure must be sought in other directions. Since the days of Semmelweiss it had been beyond doubt that the accoucheur might implant the infection, and Geddes (1926) had collected statistics of infective wounds and brought them into relation with the incidence of puerperal infection in the same areas. These statistics were interesting and striking, but seemed to fail by hinging on the assertion that streptococci were constantly present in infected wounds, to which many pathologists would be unwilling to assent. Many septic cases were beyond possibility of infection by the accoucheur, so that an endogenous infection was also a possibility in perhaps not less than 25 per cent. of all septic cases. The infective agent was usually a streptococcus, and in severe cases nearly always one of the virulent pyogenes group. Western's figures (1912) of 100 cases which were very thoroughly examined had shown this beyond question. Uterine cultures had proved that the disease was an infection of this viscus, primarily, perhaps, of the placental site or of some other raw area of the genital tract; early in severe cases the organism was not quite a specific cause of this disease, since the *Staphylococcus aureus* might produce severe and fatal infections; this organism, however, was a very rare cause, except in criminal abortion cases, which were undoubtedly due to direct implantations. It was not known how the organism reached the placental site, but it was certain that a virulent streptococcus inoculated into a tissue lesion set up symptoms within a few hours, which was seldom the case in puerperal septicaemia. In this disease there was almost always a waiting period of about two or three days after delivery; in any other disease this would be called an incubation period, a term not used in puerperal septicaemia for fear of giving grounds for the suspicion of going back fifty years or more and classing this disease with the specific infectious fevers such as scarlet fever. If they were logical and called it the incubation period, they would in this way admit that they believed some process was operating which differentiated this disease from that which usually resulted when a streptococcus was inoculated into an open wound. Attempts had been made from time to time to ally puerperal fever with scarlet fever, but few believed in any direct connexion. If there was no causal relation there was in some respects a close similarity, as for instance, it was quite likely that the recent work on scarlet fever might produce something of use in connexion with puerperal fever, especially in relation to the preparation of an effective anti-serum. Assuming that the infective agent was implanted, or was present in the genital tract at the time of delivery, there seemed to be several possibilities during the incubation period. The organisms might have to ascend from the vagina to the raw placental site and effect an entrance there; this might take time. The organisms might have to increase in numbers before any sign of activity showed. The tissues, for some puerperal reason, might not be adapted to infection, and this was delayed until some tissue change occurred and they became so. Dr. Benians knew of no clinical or experimental evidence in support of this idea. The organisms might have to increase in virulence, and he thought that the crux of the

matter lay here. If delay during the latent period meant that infection was awaiting an exaltation of virulence of the organism, it implied further that the streptococcus had not been conveyed direct from a septic wound, or, if it had, attenuation in transit had occurred, which might well be the case. From an endogenous point of view an infection by streptococci normally present in the vagina would invariably require an increase in virulence. Streptococci might be increased in virulence by the process of "passage" —that is, by passing through the body, and usually the blood stream, of a susceptible animal. It was possible that *something of this nature occurred in the human body after* the implantation of the infective agent, and that the organism acquired virulence in the tissues; quite likely it passed out of the blood stream, and was redeposited in the placental site. If such a process as this were shown to occur it would mean that the streptococci so disseminated, though they might originally be derived from the genital tract, might also come into the blood stream from other sites, as, for instance, from infective conditions of the throat; possibilities of this sort would have to be taken more into consideration, both in connexion with the patient and with her attendants.

Dr. R. SPEARS quoted two cases in which the child had been born before his arrival and no vaginal examination had been made. In one instance, that of a multipara, a child with acute influenza was in bed with the mother. On the third day the mother's temperature rose, streptococci were recovered from the blood on the fifth day, and the patient died on the tenth. In the second case, a primipara, no vaginal examination was made, but on the day after the delivery the temperature was 104°. She ran a septic temperature, with rigors, for fifteen weeks, and collections of pus were let out from the pelvis on several occasions. Blood cultures were negative twice. There had been in this case an indefinite history of shivering attacks and sweating for six weeks before the confinement.

X-RAY TREATMENT OF RODENT ULCER.

AT a meeting of the Brighton and Sussex Medico-Chirurgical Society on February 4th Dr. J. H. T. DAVIES exhibited some cases of rodent ulcer and read a paper on this subject.

Dr. Davies stated that his object in showing these cases was to dispel the cloud which seemed to overshadow the treatment of rodent ulcer by *x* rays. The patients had not been under observation for very long after treatment, and he only drew attention to the result from an aesthetic point of view. He did not imply that *x*-ray treatment was the only, or even the best, one for rodent ulcer, but while every case should be treated individually on its own merits the method he had been using for the last ten years had given very satisfactory results. A cubic centimetre or so of 2 per cent. novocain was injected under the growth, which was then scraped vigorously with a sharp spoon. The rodent tissue had the consistency of cheese, and it was easy to distinguish when healthy tissues had been reached. The excavation was found to occupy a much larger area than the original growth, and was often of a different shape. This preliminary scraping was, he thought, the most important part of the treatment. First of all the bulk of the rodent tissue was removed; secondly, the operator was enabled to judge accurately the extent of the lesion; and thirdly, the part to be *x*-rayed was freed from any trace of the skin which would be burnt by the subsequent application of the *x* rays, and so render healing of the ulcer a lengthy and painful process. A fourth advantage was that the rays were enabled to reach the deeper parts of the lesion without passing through the overlying tissue. In process of scraping such a contraindication to radiotherapy might be discovered as the invasion by the growth of cartilage or bone, when the cavity could be filled with arsenical paste, or the whole lesion be removed surgically, or diathermy be applied. Dr. Davies asserted that no surgical excision of a rodent ulcer should be begun without a preliminary scraping. He then described the preparation of a lead shield for the surrounding skin, and said that a dose corresponding to four, five, or six Sabouraud B doses of *x* rays unfiltered was used. The ulcer healed up under a scab in about three weeks' time. This operation took less than an hour to perform throughout and was quite painless, both at the time and afterwards. In the connective tissue thus exposed to the rays there was no noticeable change, nor were any subjective symptoms felt by the patient. In cases where the rodent ulcer had been on the side of the nose there was no apparent effect on the mucous membrane inside. MacLeod, who had measured the proportion of a pastille dose of unfiltered *x* rays, using a 10-in. spark-gap through the cranial wall and coverings of a child of 3, found that no more than a quarter of the dose reached the other side. Complete surgical excision was often the best and easiest method of dealing with a rodent ulcer, provided that the preliminary scraping was employed. Unfortunately rodent ulcers frequented those situations where excision was difficult or appeared unnecessarily drastic, and in such cases, and with patients who refused surgical operation, the *x*-ray treatment described gave an equal, if not a better, chance of a cure.

Nephritis.

Dr. WALTER BROADBENT read a paper on nephritis. He laid stress on the importance of McClean's urea concentration test and on the estimation of blood urea. Of chronic parenchymatous nephritis with oedema there were two types; in one the blood urea came down to normal and the urea concentration test gave 2 per cent. or more. When this type was treated by Epstein's diet of increased protein, moderate carbohydrates, and no fat, the oedema disappeared and the patient's general condition improved greatly, so that he could lead an ordinary life. The other type, with high blood urea and low urea concentration, drifted into uraemia or heart failure. In chronic interstitial nephritis the urea concentration test sank below 2 per cent. and the blood urea increased. The blood pressure rose and there was danger of cerebral haemorrhage and of heart failure, or the case might end in uraemia. In treatment Dr. Broadbent mentioned keeping the bowels active with salts and a weekly blue pill, potassium iodide, evening hot baths, spa treatment at Contrexeville or Vittal, and occasional bleeding. For uraemic asthma, purging and morphine were recommended, and for convulsions, lumbar puncture, bleeding, chloral, and morphine. With uraemic headache he said that there were often marked signs of intracranial pressure, Kernig's sign, and difficulty in making the chin touch the chest, and sometimes extensor toe reflexes. Lumbar puncture gave great relief. *B. coli* nephritis was then dealt with. In acute attacks there were rigors, high temperature, vomiting, renal pain, and profuse haematuria. Often only one kidney was affected, and that usually the right. The condition had to be distinguished from stone, perinephric abscess, retrocolic appendicitis, cholecystitis, and even malaria, when there was no renal pain. The treatment was to render the urine permanently alkaline by potassium citrate and bicarbonate in full doses, giving also a large amount of fluid to drink. In severe cases not yielding to this treatment a ureteric catheter should be passed through a cystoscope up to the pelvis of the kidney, and be left *in situ* to afford drainage. Dr. Broadbent remarked that chronic *B. coli* nephritis, though very common, was frequently undiagnosed, as the urinary symptoms were slight. It occurred in female babies, and more often in women than in men. The symptoms were headache, loss of energy, pains in joints and muscles, and intermittent pyrexia. Recurring "influenza" was often really due to this. The treatment was alternating courses of alkalis and hexamine with acid sodium phosphate, also intestinal disinfectants.

INDUSTRIAL MEDICINE.

A MEETING of the London Association of Medical Women was held at the British Medical Association House on January 25th, with the President, Miss BOLTON, in the chair; Dr. MARGARET DOBBIE-BATEMAN gave an address on some aspects of industrial medicine.

Dr. Dobbie-Bateman said she did not intend to discuss the treatment of vocational disease, but to deal with industrial medicine in so far as it represented a particular

organization of medical practice to meet a particular social service. Factory medical officers must be distinguished from certifying surgeons. The latter were invested with certain statutory powers and were required to fulfil certain statutory duties; whereas the factory medical officers were the officials of the industrial organizations in which they worked, and had no executive but only advisory powers. Their business, from the staff managerial point of view, was to prevent the engagement of people unable by reason of physical disability to do the work required of them; to forestall absence of workers, and therefore loss of work through sickness; and to obviate loss of work through lowered physical efficiency. Restated from the point of view of the workers—and on this she laid great stress—the medical officer's duty was to restrain people from undertaking work they were unable to do, and to keep them in a full and happy capacity at work. The first aim was met by a preliminary medical examination of candidates for employment. Between those completely fit and those totally unfit was a large class whose applications had to be considered with reference to several points. Standards of fitness for employment in industry need not be so rigid as standards for acceptance in the army, where men had to be fit for service in any emergency, must be interchangeable, serve over a prolonged period, and were pensionable. In productive work no one who was likely to be able to help in producing should be excluded from doing so. In practice the number rejected from those industrial occupations of which the speaker had experience need be very few. It was often possible to allocate suitable work to a candidate who would not be capable of work in certain departments, or to recommend treatment, after which the candidate was fit for any work. A knowledge of the industrial processes was therefore necessary to the medical officer. Unfortunately certain people still had an objection to a compulsory medical examination, and Dr. Dobbie-Bateman was now trying the experiment of a voluntary medical examination for applicants over the age of 16; for younger people she was convinced that compulsory examination was necessary in their own interests. For the prevention of absenteeism two procedures were essential—namely, the examination of staff returning from sick leave, if possible before they rejoined their departments, and the rule that the only pass-out given to workers leaving their posts for reasons of health should be given by the medical officer. The first rule prevented people from returning to work before they were fit to do so, and, on the other hand, the knowledge that a visit had to be paid to a medical officer acted as a deterrent to those whose headaches tended to occur on the Tuesday after a bank holiday. The industrial medical officer was also called on for first aid, for advice as to lighting, heating, and ventilation, for the determination of optimum periods of rest, and for the superintendence of canteen arrangements. There was urgent need of a dental scheme in connexion with industrial medicine, and an ophthalmological service would also be of value. Finally, research into industrial dermatitis and industrial fatigue should be actively pursued.

JAMES MACKENZIE INSTITUTE.

At the opening meeting of the Spring Session of the James Mackenzie Institute for Clinical Research, St. Andrews, on January 18th, the honorary director, Dr. MAITLAND RAMSAY took as his subject toxic iritis. He deprecated the use of the term rheumatic iritis because, though sometimes associated with chronic arthritic states, iritis practically never occurred in rheumatic fever. In the course of his lecture Dr. Ramsay described fully the symptoms and treatment of the condition. He said, however, that he had chosen the subject, not as a lecture on eye disease, but because it so aptly illustrated the general principle that the cause of disease was not necessarily to be found in the organ manifesting the symptoms. Toxic iritis being a local manifestation of a general state, local treatment was essential to its relief, but cure was not obtained until general treatment had removed the underlying cause, and so prevented recurrence. For success general treatment must depend upon recognition of the toxic process. In many cases the focus of infection was found in the teeth, the tonsils, the nasal sinuses, or the intestinal tract, but in others it followed after an attack of some general infection such as influenza. In some cases the source of the infection remained a matter of conjecture, and the iritis was then termed idiopathic, but it was difficult to understand how an iritis could occur in a healthy patient. When, for example, a posterior synechia interfered with the intraocular circulation and tension, the local symptoms were intense. The relief afforded by iridectomy was so complete that apparent cure resulted, but if general treatment was discontinued recurrence of the inflammation in the affected or even in the healthy eye was to be expected. Operation was a confession of failure, and if its dramatic results led to neglect of general treatment disaster would inevitably follow.

On February 1st Dr. ORR gave an address on the later views of Mackenzie on the nature of cardiac action, with particular reference to the phenomena of heart-block. Mackenzie's work, he said, was the subject of adverse criticism, mainly on the ground that it was purely speculative.—Mackenzie was a speculative thinker, but the views he expressed latterly were based upon prolonged clinical observation. In view of this criticism it was important to examine Mackenzie's position critically in the light of modern experimental research. This position was distinctive in its conception of the Purkinje system of the heart—the nodes and bundle—as the regulating and controlling structure of the organ. The heart muscle only contracted in response to stimuli reaching it from this source. Conduction in the bundle was attained, not by the passage of an impulse along a conducting structure, as that, term is generally understood, but by successive stimulation of contiguous cells in the bundle, each one discharging an individual impulse. For this reason Mackenzie described the nodes and bundle as the "genetic" system of the heart. Dr. Orr then discussed recent experimental work upon the passage of the excitation process in the various parts of the heart. It was generally agreed that the S-A node was normally responsible for initiating the cardiac contraction. As regards the spread of the excitation wave through the auricle, the balance of evidence, having regard to direction and spread and rate of transmission, was greatly in favour of a spread through the auricular node. A spread between the S-A and A-V nodes by means of a distinctive path had not been demonstrated, though an experiment by Mines showing the persistence of electro-cardiographic deflections after muscular contraction had been abolished was suggestive. In the ventricle there was no doubt that the spread of excitation was accomplished by means of the bundle and its ramifications. The question centred upon the means by which this spread was accomplished, whether by simple conduction or by cell stimulation. Experimental observation made it clear that the A-V node could not be regarded as a simple conductor, but that it acted as a centre for the discharge of impulses. The phenomena of the nodal extra-systole and of reversed heart-block demonstrated this conclusively. With regard to the bundle, the question presented itself as to the source of the ventricular beats in complete auriculo-ventricular dissociation. That there was no "set" ventricular rate was shown by the fact that, in a single individual the subject of complete heart-block, the ventricular rate varied at different times from 30 to 45 per minute. The electro-cardiogram in conditions of complete heart-block showed that the excitation wave entered the ventricle supraventricularly. It presumably had its origin either in the A-V node or in the supraventricular part of the bundle immediately peripheral to the lesion. This view was accepted by many experimental observers, and the trend of recent work appeared to be in the direction of regarding the whole Purkinje system as essentially a stimulus-producing structure. Mackenzie's conception of the Purkinje system as a "genetic" structure afforded a complete and consistent explanation of the phenomena observed experimentally and clinically. The only other alternative was to regard it as a conducting mechanism which, in certain circumstances, acquired the capacity of stimulus production.

Reviews.

A CYCLOPAEDIA OF PATHOLOGICAL ANATOMY AND HISTOLOGY.

Two volumes of the cyclopaedia of pathological anatomy edited by F. HENKE and O. LUBARSCH were reviewed in the JOURNAL of March 6th last (p. 427). They contained altogether nearly 2,000 pages. These were Volumes II and VI. The first part of the fourth volume,[1] issued a short time ago, contains over 1,100 pages. The volume has to do with the morbid anatomy of the alimentary system, including diseases of the pharynx, the tonsils, salivary glands, the stomach, the intestines, and the peritoneum. Acute and chronic ulcers of the stomach and duodenum are described in great detail and the text is illustrated by some excellent coloured pictures. An account of experimental work and clinical investigations is followed by a summary. Briefly, the conclusions are that simple ulcers and haemorrhagic erosions are due to infarct of the mucous membrane. The area affected may be from one to four centimetres in width, but may subsequently enlarge. Arterio-sclerosis may be the initial vascular lesion, and embolism may arise after operation or be due to sepsis, and in young individuals the vascular disturbance may be neurogenic. A chronic ulcer may be started by the same causes as the acute, but special features of the physiology and anatomy of the stomach play a part; mention is made of the increase in the acidity of the gastric juice, and of irritation of the ulcer by movements of the stomach. The ulcer may cause the movements to be augmented and to become cramp-like, perhaps constricting the vessels. Associated endarteritis is important. The same facts hold for duodenal ulcer, and pyloric spasm and hypertrophy dependent on neurogenic influences are factors also. The so-called gastric street along the lesser curvature is of importance in both acute and chronic ulcers because the vascular supply and the nerves have here a special distribution. The literature cited covers forty-two pages.

The section on the tumours of the stomach is most excellently illustrated. Many aspects of the etiology of carcinoma are discussed, including, of course, the relation of chronic ulcer to carcinoma. The author of this section, Professor Dr. R. Borrmann-Bremen, concludes his long analysis by saying, "I personally hold the view that the number of 'ulcer carcinomas' definitely proved, which can stand the most searching criticism, reaches only 1 or 2 per cent."

The eighth volume, which has also been published, is devoted to the glands of internal secretion. More than half of its thousand pages are devoted to the thyroid and parathyroid glands; the sections on the thymus, pineal, pituitary, and the suprarenal and chromaffin system occupy the remainder. There are three hundred and fifty-eight illustrations, some of which are coloured. The value of the volume would have been increased if to each section a summary of what the author considers may be regarded as well attested knowledge had been appended. This is done in some cases, but not in all. A very full account is given of exophthalmic goitre. Despite the vast amount of attention devoted to its pathogenesis many features are still obscure. The author's conclusion is that a combination of factors are concerned in its production; there is first the abnormal constitution, in which the most important factor is the special reaction of the nervous system. Hyperthyroidism, it is believed, is brought about either through psychical influences on the secreto-motor nerves of the thyroid gland, or by chemical means through the increased activity of associated organs, or finally through disease processes in the thyroid itself. The theory that endemic goitre is primarily due to insufficiency of iodine is accepted. This insufficiency, it is supposed, renders the performance of the functions of the thyroid difficult, and then accessory causes, such as a diet deficient in fat, water-borne infections, lack of sunlight (and of ultra-violet light in particular), as well as other factors, induce the phenomena of thyroid deficiency.

The author of the section on the pineal gland, despite the lack of physiological evidence, believes that structure, comparative anatomy, and cytology establish its glandular nature. This conclusion is in harmony with the observations of human pathology, to the effect that it plays a part in the production of the sexual characters and activity. Knowledge of the pathology of the parathyroid is in just the opposite state. There is abundant evidence of its association with tetany, with calcium metabolism, and therefore with the pathology of such diseases as osteomalacia, but morbid anatomy has no special changes to describe.

The relation of the pituitary to certain diseases is set out in tabular form, the substance of which may be reproduced here; it is interesting in view of recent work which has tended to extend the anatomical basis of these disorders to the adjacent areas of the diencephalon.

Relation of the Pituitary to Disease.

Acromegaly. Excessive function of the eosinophilous cells of the hypophysis.

Giantism. In the acromegalic type through excess of the secretion of the eosinophilous cells before the cessation of bone growth. In the eunuchoid type, probably a combination of hypofunction of the sexual glands and hyperfunction of the hypophysis.

Hypophyseal Dwarfism. Disappearance or marked reduction of the function of the anterior lobe before the cessation of bone growth. The most common pathological finding is a tumour not affecting the anterior lobe, but the duct of the hypophysis; the condition may be congenital, or may come on in infancy or perhaps later.

Hypophyseal cachexia occurs predominantly in women, and is attended by disappearance or great reduction of the function of the anterior lobe.

Dystrophia Adiposo-genitalis. Destruction of the correlation between the hypophysis, probably the anterior lobe, and the diencephalon.

Diabetes Insipidus. Destruction of the function of the nervous part of the hypophysis (posterior lobe, infundibulum, floor of the third ventricle).

The twelfth volume is on the ear. The gross anatomy of the region is shown in some excellent coloured pictures, and the histology is most adequately rendered by the reproduction of serial sections through the ear. A long section on the inflammatory diseases is followed by one on the regressive, degenerative, and dystrophic changes; others deal with tumours, malformations, injuries, foreign bodies, and parasites. An attempt is made to correlate the effects of disease with the theories of hearing. The tympanic membrane is rarely affected alone, but it would appear that lesions of it which do not destroy its integrity, such as partial thickenings and patches of calcification, have only a slight effect on the acuity of hearing. Scar formation and perforation seem mainly to limit the appreciation of low notes. The acuity of hearing is thought to be dependent on the preservation of the stapes and its mobility. If it becomes fixed hearing is made much more difficult, and there is a loss of sensibility to the higher tones. Though the drum, malleus, and incus be absent, if the ear is otherwise normal there is appreciation of low tones unless the stapes becomes fixed. Fixation of the ossicles without defect of the internal ear produces only very slight change in the acuity of hearing. For the author's views of the results of derangement of the fenestra rotunda, and of the cochlea, we must refer our readers to the volume itself. The author remarks, in conclusion, that it is extremely difficult to correlate the changes in hearing with the pathological findings. There are even cases of complete deafness in which no changes are found peripherally and in which it is fairly certain that central changes were absent.

There can be no doubt that this work represents a high standard of achievement. Each section contains, in addition to a discussion of the pathology of the organ, an account of the anatomy, physiology, and chemistry, and of the methods of investigation.

IV, pp. xiv + 1127, 377 figures; R.M.156, bound R.M.159. Bd. VIII. pp. xii + 1147, 358 figures; R.M.165, bound R.M.168. Bd. XII, pp. xii + 802, 640 figures; R.M.81, bound R.M.87.)

OBSTETRICS: DIFFICULT LABOUR.

DRS. CAMERON and HEWITT of Glasgow are already known to the profession as writers on obstetrical conditions, and they have recently added to their list of publications a book entitled *Difficult Labour*.[1] It is, perhaps, unfortunate that they have chosen a title which for many years has at once brought to mind the classical work of Herman, but it must be admitted that the character of the book justifies its name. In some three hundred pages the authors have endeavoured to cover the field of difficult obstetrics from the point of view of the general practitioner. This aim has been accomplished, for the most suitable lines of treatment for the anxious cases in midwifery practice are well described. It is evident that the work is more or less a record of the authors' clinical experience. The three main sections of the book deal with delayed labour, with labour complicated by haemorrhage and toxaemia, and with obstetrical operations; in two shorter sections maternal and foetal complications of labour and ante-natal supervision are discussed. No part of the subject is omitted; the chapters are written from the practical standpoint, and purely theoretical questions receive no attention. Perhaps the best chapter in the book is that on the use of forceps, and many pages are rightly devoted to the commonest operation in midwifery practice. The indications for forceps application and the value of the instrument in cases of pelvic deformity are fully considered, and attention is directed to the risks involved when the instrument is used in unsuitable cases. The authors advise conservative treatment of concealed accidental haemorrhage unless such treatment results in no clinical improvement; they base their opinion on the view that the uterus in such cases is in a state of painful spasm, which should be relieved by the use of morphine, repeated if necessary. The arguments brought forward point strongly to the correctness of this view. Hendry's method of controlling post-partum haemorrhage is severely criticized, but others will agree with Hendry's claim that the method is of value in many cases. The subjects of the albuminurias of pregnancy and eclampsia receive full attention; the authors distrust the value sometimes attached to the results of biochemical investigations of toxic cases. Few will agree with the practice of routine sterilization after Caesarean section; the writers seem to overlook the fact that the relative sterility after the operation is often voluntary owing to the patient's desire to avoid another section. This opinion has been expressed by Dr. Herbert Spencer, and is held by many other obstetricians. The subject of uterine inertia receives less attention than is due to so common a cause of delay in labour; it is dismissed in less than a couple of pages, while a page is devoted to the surgical procedures of extraperitoneal Caesarean section and plastic operations on the pelvic girdle, both matters of little moment to the general practitioner. The book has a definite place in the library of the medical man, its value lying in the clear and concise manner in which the various subjects are discussed and the general soundness of the views expressed.

The sixth edition of EDGAR'S *Practice of Obstetrics*[2] has been revised for publication by Dr. N. W. VAUX. The popularity of the book in the United States is shown by its many editions. It is a large volume, and readers will find that no part of the subject has been omitted, while it contains information on subjects not often dealt with in textbooks. After an opening discussion of the more theoretical parts of midwifery—development, ovulation, and menstruation—there follow sections on pregnancy, labour, and the puerperium. Here a rather peculiar arrangement has been adopted, for the pathology of pregnancy is discussed before touching on normal labour, and the pathology of labour before the normal puerperium is dealt with, a plan which it would be thought must tend to produce confusion in the mind of the student. The sections are themselves well written and present the essential points clearly. That on the management of the infant is worthy of special mention. Resort to manual dilatation of the cervix is advocated in many cases of placenta praevia, but we would suggest that this is risky advice for the average student, for the cervix suffers laceration only too easily in these cases. External podalic version, which is a valuable manœuvre in many cases of placenta praevia, is not mentioned. The discussion on the treatment of eclampsia leaves the reader in doubt on the question of emptying the uterus; surely there is now no need for hesitation on this important question. Obstetrical operations are described at the end of the book. Pubiotomy is mentioned only to be condemned as an obsolete procedure, and this probably is in general accord with modern teaching. We are surprised to find no mention of the combined cranioclast and cephalotribe as an instrument for craniotomy operations. We can commend the book to those who prefer a large treatise, but it will probably appeal more to the qualified medical man than to the undergraduate. The numerous figures and illustrations are excellent and well reproduced, but too many printer's errors have been left uncorrected.

DISEASES OF THE ENDOCRINE SYSTEM.

THAT the second edition of Dr. ZONDEK'S book on diseases of the endocrine system[4] has appeared within three years of the first indicates that it has been appreciated by the medical profession.

The general scope of the book is unaltered, and the greater portion of the volume is occupied by the descriptions of the outstanding types of endocrine disorders. The first chapter has, however, been extended, and the author discusses in detail the relation between the action of hormones and the ionic milieu of the blood in an inactive form, and the relation of the milieu of the cell to the blood in an active form, and are only activated at their site of action, and advances the hypothesis that the action of a hormone is not a constant effect, but is very largely dependent on the nature of the milieu upon which it acts. In particular he associates increased vagal action with excess of potassium, and increased sympathetic action with excess of calcium. This is a very interesting but very difficult problem, and we are of opinion that the experimental evidence available is scarcely adequate to justify the author's generalizations.

The book concludes with a few pages of selected references. It is, of course, impossible for anyone to keep abreast of the colossal literature on endocrine secretions, but the author has omitted some recent work of first-rate importance, such as the researches of Abel on the nature of the active principle of the parathyroid gland.

As regards the vexed question of endocrine therapy, the author shows a healthy scepticism; in particular he mentions that his results with most ovarian preparations have been almost completely negative; and on page 358 he says: "A large number of clinical communications evidence a marked lack of critical capacity on the part of the authors, since they ascribe any results following ovarian preparations immediately to specific products assumed to be present. B. Zondek informs me that he also could stop amenorrhoea of some months' duration by non-specific remedies such as proteins."

The numerous illustrations were an outstanding feature of the first edition of this book, and in the new edition their number has been increased to 220. They will be found very useful by anyone who wishes to identify unusual forms of abnormalities due to endocrine deficiency.

A FRENCH TEXTBOOK OF MEDICINE.

IN Dr. JOURNÉ'S book on medical pathology,[5] the second edition of which has recently been issued, the whole domain of medical pathology is sketched in outline. He calls it a *Précis*, but it contains over fifteen hundred pages.

[4] *Die Krankheiten der Endokrinen Drüsen.* Von Dr. Hermann Zondek. Zweite, vermehrte und verbesserte Auflage. Berlin: J. Springer. 1926. (Roy. 8vo, pp. ix + 421; 220 figures. R.M.37.50.)

[5] *Précis de Pathologie Médicale.* By M. Journé. Second edition, entirely revised. Paris: N. Maloine. 1926. (Cr. 8vo, pp. 1520. 40fr.)

The orthodox method of exposition has been adopted; a short definition of each disease is followed by a concise account of the etiology, pathological anatomy, symptoms, and so forth. Details concerning pathological anatomy have, however, been considerably curtailed, only such facts being included as are indispensable to the proper understanding of the disease. Selection has also been exercised in dealing with the symptomatology. The aim has been to render descriptions as concise as possible, but sufficiently complete to include all cardinal symptoms, while those of minor importance, of inconstant occurrence, or presenting difficulties in clinical demonstration, have been omitted. Technical laboratory methods have been briefly referred to where they constitute important adjuvants in clinical diagnosis.

The arrangement of the book is partly on an anatomical, partly on an etiological basis. The majority of the diseases are described under the several anatomical systems, while the first five chapters are devoted to infectious diseases, parasitic diseases, intoxications, affections due to the action of physical agents, and nutritional diseases. The value of a book of this kind depends, not only on the completeness of the information within the assigned limits, but also upon the information being up to date. The author refers to the difficulty of keeping a textbook abreast of the continuous and rapid advance of medical science. After the lapse of a few years a medical work is antiquated. On the other hand, the multiplicity of medical doctrines with which an author is confronted is disconcerting and suggests reflections as to the possible vanity of certain pathological explanations. In this matter there is room for the exercise of discretion, and the author has endeavoured to include current doctrines which would be regarded as essential in an accurate sketch of the existing features of the science.

NOTES ON BOOKS.

PROFESSOR JEAN PIAGET of Neuchâtel has written a most interesting book with the title in its English translation of *The Language and Thought of the Child*,[6] giving the result of a long investigation into the mind processes of the child. How does a child think, and what is the basis of his reasoning? Why does he think and say what he does? Why is his curiosity so easily satisfied (a habit Binet considered one of the features of imbecile mentality)? Why does he affirm and believe things manifestly contrary to fact, and how and by what steps is his incoherence gradually superseded by the logic of adult thought? According to Professor Piaget the problem of the child mentality has been thought of as one of quantity, whereas he states it as a problem of quality. If the child mind appears opaque to adult observation it is because it belongs to a different kind of thought—autistic or symbolic thought—which the adult has long since left behind him or suppressed. Piaget's method has been to let the child talk and to observe the manner in which his thoughts unfold, allowing him to take the lead, and to talk freely with a minimum of questioning. It would seem that up to a certain age the child thinks and acts more egocentrically than adults; children share each other's intellectual life less than we do. When they are together they seem to talk to each other a great deal more than we do about what they are doing, but for the most part they are only talking to themselves. The adult keeps silent far longer about his action, and his talk is almost always socialized. The book is most suggestive and informative, and worthy of close study by teachers and psychologists.

Dr. GANS has sent us the first volume of his monumental work on the histology of diseases of the skin.[7] Although it contains over six hundred pages and is copiously illustrated, it deals only with atrophies, dystrophies, and inflammatory changes due to bacterial infection. The effects of mycotic infections, animal parasites, congenital abnormalities, and tumours are left for future volumes. In contrast with Unna's work on the same subject published in 1894, which was founded principally on that author's personal researches, the present treatise, owing to the great increase of knowledge of the subject, consists very largely of a critical summary of the results obtained by numerous workers. When necessary, however, the author, who is a highly skilled pathologist himself, indicates his own position when debatable points come under discussion. The illustrations, the majority of which are coloured, are exceedingly clear and helpful, and many of them are drawn from the author's own preparations. The bibliography is full, and well arranged for easy reference. In fact, Dr. Gans has produced a book which deserves the attention of every dermatologist and clinical pathologist, and we hope that the volumes promised for the future will not be unduly delayed.

The first volume of the second edition of Professor TANDLER'S textbook of anatomy[8] comprises the sections of osteology, arthrology, and myology—sections which, if they present little scope for originality in the text, are not so unpromising in regard to illustrations; these, reproduced on heavy paper, form in fact the main feature of the volume. As is usual in German textbooks, the mechanics of the various joints are considered at greater length than in English textbooks, while—another generic difference—the paragraphs introductory to the sections are written from a broader general biological standpoint. As an indication of the size of the work it may be stated that the space allotted to each section is slightly less than that given to the corresponding section in *Gray's Anatomy*.

For the last seven years each annual issue of *Burdett's Hospitals and Charities*[9] has been subjected to careful revision and condensation. To a great extent the aim, which is to provide a more convenient though still comprehensive register, has been attained for the time being, and in the thirty-seventh issue, which has just appeared, there is no radical alteration, though it is larger by some sixty pages than last year. A newcomer in its contents is a short statement about the central bureau of hospital information, which is now conducted by the Incorporated Association of Hospital Officers, at 28, Bedford Square, W.C.1. This bureau, which was established in 1925, works in co-operation with the Information and Service Branch of the Charities Board of Victoria, the Hospital Board Association of New Zealand, and the Lord Mayor's Hospital Fund of Melbourne. The hope is expressed that further institutions of this kind will appear in other Dominions and outside the Empire. The review of the conditions of voluntary hospital finance indicates that there is steady progress towards a co-ordinated system of hospital services, which will enable the individual units to function more effectually. The directory of institutions includes universities, colleges, and schools; hospitals in the Empire and in foreign lands; educational and charitable funds and institutions; nursing associations throughout the world; and periodicals in the United Kingdom dealing with medicine and allied subjects. As a reference book in these respects this year-book retains its unsurpassed value.

The *Minutes of the General Medical Council and of its Various Committees*[10] for the year 1926 have now been published with fifteen appendixes in a volume which includes the customary detailed reports of the two sessions of the General Medical Council and those of the English, Scottish, and Irish Branch Councils. Sir Donald MacAlister's two presidential addresses, which were published in our columns when delivered (SUPPLEMENT, June 5th, 1926, p. 205, and November 27th, p. 225), are also printed here. The longest of the appendixes comprises the interim report of the Education Committee on the progress made throughout the country towards the readjustment of the medical curriculum in accordance with the resolutions adopted by the Council on May 26th, 1922, which came into force on January 1st of the following year. The *General Index* to the Minutes of the General Medical Council and of its Executive and Dental Committees, and of its three Branch Councils, from 1903 to 1926, has also been published. It relates to volumes xl to xliii of the *Minutes*. The plan of previous editions has been followed, and each subject is fully indexed, the references being arranged chronologically, in many cases special subheadings being inserted. Since 1909 this useful work of reference has been kept standing in type and brought up to date from year to year, but in the interests of economy a number of entries are annually curtailed where experience shows that this can be done without impairing the usefulness of the index.

[6] *The Language and Thought of the Child.* By Jean Piaget, Professor at the University of Neuchâtel. Preface by Prof. E. Claparède. Translated by Marjorie Warden. The Dance of Çiva: Life's Unity and Rhythm,[1] by COLLUM, belongs to the "To-day and To-morrow" Series, which are described as written by some of the most distinguished English thinkers to provide a stimulating survey of the most modern thought in many departments of life. The Eastern dance of Çiva, a representation of which forms the frontispiece, symbolizes life and death in a rapidly turning wheel, on the top of which a rather weird and scantily clothed female figure is represented as dancing. Written in what some may consider a clever style, with hints of underlying learning, it appears to argue that Western knowledge and culture are inferior to the Oriental. The medical profession comes in for reproaches which, if it reads them, it may accept with chastened resignation.

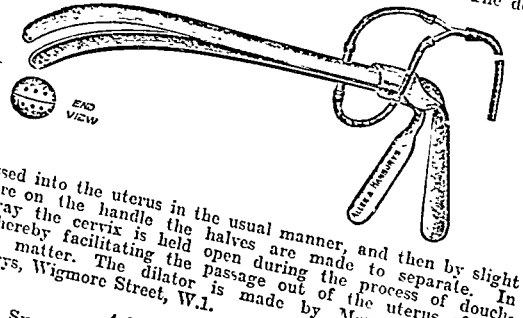
PREPARATIONS AND APPLIANCES.

Ephedrine.

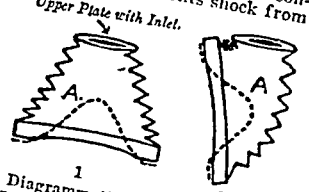


EPHEDRINE is obtained from the Chinese drug Ma Huang, which has, it is said, been used in China since 3200 B.C. The active principle, ephedrine, has recently been introduced into clinical medicine; its full chemical name is β-phenyl-β-hydroxy-α-methyl ethyl methylamine. The drug has been introduced to Western medicine by the researches of Read, Chen, and Schmidt of the Peking Union Medical College. Ephedrine is a sympathetico-mimetic amine, and therefore its pharmacological action is very similar to that of adrenaline, but ephedrine has the great practical advantage over adrenaline of being a stable compound that produces an effect lasting for an hour or more when given by the mouth. It produces powerful mydriasis when instilled into the conjunctiva, and when given by mouth is followed by a rise of blood pressure, which commences in about half an hour and lasts for several hours. Ephedrine has been used with success in place of adrenaline in the treatment of hay fever and asthma. The value of adrenaline in therapeutics has been limited by the fact that it cannot be given by mouth and has a very transient action. Neither of these objections appears to apply to ephedrine, and the drug ought to prove of therapeutic value in a number of different ways. The dose of ephedrine is from 1/2 to 2 grains. The drug has been prepared for clinical use by Messrs. Burroughs Wellcome and Co. and also by the British Drug Houses.

Concentrated Scarlet Fever Antitoxin.

The Wellcome Physiological Research Laboratories have produced an interesting new product—a concentrated scarlet fever antitoxin. It has been known for a few years that injection of the *Streptococcus scarlatinae* into horses resulted in the formation of an antitoxin, but progress was hampered by the fact that no animal test was known by which the activity of the product could be measured, and all tests had to be made on human volunteers. A test on rabbits has been discovered that is believed to be satisfactory, and this has rendered possible the production of concentrated serum. The dose recommended is from 20 c.cm. in a severe case up to 50 c.cm. in a very severe case. The antitoxin has proved valuable in a number of trials, but it cannot be expected to produce any direct action on the septic complications of scarlet fever. It is, of course, obvious that a considerable time must elapse before it is possible to make any certain estimate of the clinical value of a remedy of this character. The antitoxin is supplied by Messrs. Burroughs Wellcome and Co.

Uterine Douche Dilator.



Dr. J. E. HEPPER (Brenchley, Kent) has devised an instrument for rendering uterine lavage more effective. The uterine douche dilator shown in the illustration is made in two halves, which, when closed, resemble an ordinary uterine douche. Each half is hollow and is perforated at the distal extremity, so that fluid will pass through it and be sprayed out at the end. The douche

is passed into the uterus in the usual manner, and then by slight pressure on the handle the halves are made to separate. In this way the cervix is held open during the process of douching, thereby facilitating the passage out of the uterus of any foreign matter. The dilator is made by Messrs. Allen and Hanburys, Wigmore Street, W.1.

A Modified Ether Inhaler.

Mr. R. SHAFFER, M.B., Ch.B. (Manchester), has devised an ether inhaler with an adjustable outer chamber for use in conjunction with an open ether mask. "By the open ether method," he writes, "a vapour strength of 12 to 14 per cent. is attainable, and whilst this safeguards against overdose, it has certain disadvantages. Chief amongst these is difficulty in inducing anaesthesia and securing adequate muscular relaxation in powerful subjects. There is thus a tendency to resort to chloroform at a stage when its use is to be particularly deprecated. The necessary result can be obtained by ether alone if provision be made for concentration of the ether vapour. By the use of the apparatus here described the induction period is shortened and the amount of ether used greatly reduced. The carbon dioxide in the patient's expired air is conserved and acts as a stimulus to breathing and prevents shock from acapnia. The chamber can be used in conjunction with the vapour method, or, if desired, can be converted into a closed inhaler by the adjustable cover. Being adjustable, it is equally efficient whether the head be in the medial or lateral position. The apparatus consists of (1) an upper metal plate with a central aperture through which the ether is dripped; (2) a lower base plate fitting over the Schimmelbusch; (3) tubular bellows attached above and below to the plates, enabling the upper plate to be kept horizontal irrespective of the angle of the mask and base plate. Anaesthesia is conducted by the ordinary drop or vapour methods, and the appliance provides an efficient secondary chamber for the concentration of the ether vapour and conservation of the carbon dioxide. The aperture being always at the top of the chamber, irrespective of the position of the patient's head, the vapour is retained by its own weight, and complete conservation is obtained by closing the cover. Since almost all the ether is actually inhaled by the patient, instead of being disseminated into the atmosphere, a great saving of ether is effected. In Manchester the apparatus has been used with success in powerful, muscular, and alcoholic subjects in whom the open method and semi-open methods have failed to produce adequate muscular relaxation. The model used was made by Messrs. James Woolley, Ltd., Manchester.

Diagrammatic illustration of the apparatus. 1, Position at beginning of induction. 2, Position during the operation. The Schimmelbusch shown by dotted line. A, A, Outer chamber of ether surrounding the Schimmelbusch in both positions.

INTERNATIONAL OPHTHALMOLOGICAL CONFERENCES.

AT the meeting of the convention of English-speaking Ophthalmological Societies held in London in July, 1925, the President, Mr. E. Treacher Collins, was invited to appoint a committee of five to obtain the co-operation of ophthalmologists of all countries for the promotion of international ophthalmological congresses. Early in October this committee sent out a general notice to ophthalmological societies and ophthalmologists in all parts of the world, asking them to nominate two delegates from each country to confer on the question of the re-establishment of international congresses, and on other matters of international ophthalmological interest. The response to that notice has been widespread; already all the principal countries of the world have indicated their approval of the project, and, in the great majority of cases, have named their delegates. The provisional arrangement is that the committee shall, in response to an invitation from the Netherlands Ophthalmological Society, meet at the Hague on Tuesday, July 12th. Mr. E. Treacher Collins will attend as convener of the conference. The delegates nominated are:

Argentine: Professors Enrique B. Demaria and Raúl Argañaraz.
Austria: Dr. Adalbert Fuchs and Professor Dr. Josef Meller.
Belgium: Drs. Henri Coppez and Léon Weekers.
Bulgaria: Professor C. Pascheff and Dr. Slavoff.
China: Dr. T. P. Lee.
Czecho-Slovakia: Dr. A. Elschnig and Professor Leser.
Denmark: Drs. K. K. K. Lundsgaard and Chr. F. Bentzen.
Finland: Professor V. Grönholm and Dr. Y. G. Lindberg.
France: Drs. Morax and Terrien.
Germany: Professors Axenfeld and Wessely.
Great Britain: Sir J. Herbert Parsons and Mr. Leslie Paton.
Holland: Professors G. F. Rochat and J. van der Hoeve.
Hungary: Professors Emile de Grósz and L. de Blaskovich.
Japan: Professors S. Ishihara and Oguchi.
Norway: Professor Hagen and Dr. Malling. Substitutes, if necessary, Drs. Gjessing and I. Schiötz.
Rumania: Drs. C. Pandelescu and N. Rásvan.
Spain: Drs. M. Marquez and F. Poyales.
Sweden: Professors Fritz Ask and Albin Dalén.
Switzerland: Professor J. Gonin and Dr. Ernst Pflüger.
United States: Drs. G. E. de Schweinitz and Arnold Knapp. Substitute, if necessary, Dr. Walter R. Parker.

The following countries have intimated their intention of taking part, but have not yet nominated their delegates: Cuba, Italy, Poland, and Jugo-Slavia. No reply has, so far, been received from Brazil, Chile, Egypt, Greece, Peru, Portugal, Russia, and Venezuela.

A MEDICAL REVIEW OF SOVIET RUSSIA.*

V.—THE MEDICAL PROFESSION, SOVIET SCIENCE, AND SOVIET SANITATION.

BY

W. HORSLEY GANTT, B.Sc., M.D.

(Formerly Chief of the Medical Division of the American Relief Administration, Leningrad Unit.)

PART III.

WORK AND ORGANIZATION OF THE PUBLIC HEALTH DEPARTMENT.

As the public health department (Narkomzdrav)† in Russia is an innovation of the Soviet Government—there was none under the Tsar—its organization and work merit some description.

The Narkomzdrav is under central control and in close relation with the other branches of the Government. The Commissar (Minister) of Health, Dr. N. Semashko, is also a member of the "Tsik"‡ or Central Executive Committee, which constitutes the pinnacle of power in the Soviet Government, having for its other members the other people's commissars (Ministers), Zinoviev, Trotsky (formerly), Lunacharsky, Rykoff, etc. Each State has a public health department, or Gubzdrav, at whose head is usually a Communist doctor having control of the public health affairs of his district and responsible to the central authority.

The work of the Narkomzdrav is divided among departments, each administered by a competent physician: (1) sanitary-epidemic, including sections for tuberculosis, syphilis, malaria, etc.; (2) therapeutical; (3) department of sanatoriums; (4) war sanitation; (5) railroad and steamship sanitation; (6) maternity and child welfare; (7) care of youth, including departments for athletic sports and physical culture; (8) control and organization of scientific research work. Practically all of the medical work in Russia is under the Narkomzdrav, but the medical schools are under the People's Commissar of Education, Lunacharsky. The post-graduate courses for doctors, however, are under the Narkomzdrav.

The work of the various departments is unified and co-ordinated by the central control and frequent conferences. It has obvious advantages over the former poorly organized work under the Tsar. Professor A. A. Vladimiroff, director of the Institute of Experimental Medicine, said: "Under the old system, that now being done by the Narkomzdrav was inefficiently handled by fourteen different organizations, which had no connexion one with the other." Each department of the Narkomzdrav has a scientific section with laboratories for research to direct the practical work. For example, the tuberculosis section has a central scientific institute in Moscow under which are many branch institutes in different parts of Russia. These laboratories are not fully established in all the departments, and some years will be required for the complete elaboration of this new plan.

Dr. Semashko, the head of the Narkomzdrav, who has the twofold duty of being a Communist leader and of caring for the health of a territory occupying one-half of Europe and one-half of Asia, was a country doctor on the middle Volga (Samara) before the revolution. He is an energetic and efficient organizer. He has won the admiration of all, including even political foes, by his integrity and justness. In outlining his work to me, he said:

"The present tendency of our work is prophylactic and sanitary—education of the peasant and workman to care for himself. This was entirely neglected under the rule of the Tsar. The whole population will be brought under medical examination and sanitation, by means of our newly installed medical points throughout the country, and the polyclinic and dispensary. In these we have also a complete system for carrying on social welfare work."

To illustrate, I will outline the work of several of the departments of the Narkomzdrav.

The antituberculosis work is modelled on the Edinburgh scheme, and is indirectly indebted to Sir Robert Philip for its inspiration. Besides the organization of medical points, ambulatory, dispensary, and polyclinic groups designed to care for prophylaxis, treatment, propaganda, etc., there were organized in 1922 in every large institute a system of "cells" or units claimed to be original in Russia. They are made up of workmen—voluntary workers—who are members of the organization to which they belong. The units are of various kinds—tuberculosis, venereal, sanitation (ventilation, heating), maternity, etc. The work consists in the distribution of educational health pamphlets, the carrying on of public health campaigns, the detecting of the sick and bringing them to the physician, and so on. By thus shifting part of the responsibility on to the working man, he is taught to take an interest in and have a care for his own health. The principle involved is that of Dr. Semashko: "The health of the working masses should be in the hands of the workmen." Patients detected by the medical units are sent to the ambulatories, which exist in every factory and important institution, for first aid and preliminary examination, and if more attention is needed, the physician sends them on to the polyclinic or dispensary. Each dispensary consists of a medical and a social section. The latter investigates homes, sanitation, registers social and infectious diseases, and carries on educational propaganda. Separate departments exist for children, the youth, tuberculosis, venereal disease, obstetrics, etc.

In connexion with the dispensary, polyclinic, and medical "cells" are the Councils of Social Help, consisting of the staff of the dispensary and of representatives of trade unions, factories, schools, and Government departments. Their duty is to provide help for the individual patient.

The following is a quotation from Professor A. A. Vladimiroff, to whom I am greatly indebted for other explanations in regard to public health work in Russia.

"Before the revolution there was no systematic fight against tuberculosis in Russia. In 1918 there was organized for the first time a special department for tuberculosis in the Narkomzdrav. Once a year there is a tuberculosis week; the newspapers, schools, museums, cinemas, present the subject to the public; pamphlets and posters are distributed. Educational propaganda is now one of the chief factors of the work."

Dr. Semashko, in commenting on the work against syphilis, said to me:

"Prostitution, which is one of the greatest causes of syphilis, has been officially prohibited by the Soviet Government and is punishable by fine. There are now no houses of prostitutes in Russia. A vigorous campaign is to be made again this autumn against venereal disease. Women's organizations are finding employment for the prostitutes. Although there are still some places in Soviet Russia where syphilis is very prevalent, there is less in the Red Army than there was in the Tsarist Army."

Malaria, now three times more frequent than in pre-war times, is demanding the attention of several branches of the Soviet Government. Before the revolution there was no systematized campaign against this disease. The methods enforced under the initiative of the Narkomzdrav are: (1) obligatory registration by card of the sick; (2) the establishment (in 1922) of an institute in Moscow for professional study of malaria with branch institutes in the large cities; (3) the opening of 113 antimalarial stations between 1921 and 1925; these constitute the primary units, and consist of dispensary, a small section for clinical observation, a laboratory, and a museum for sanitary instruction; (4) direction of the work by a central commission in Moscow with subcommissions throughout Russia; (5) compulsory co-operation of the other Government departments; (6) propaganda by instruction in the schools, cinemas, newspapers, and factories; (7) exemption of quinine from taxation and the distribution of a certain amount free (10,000 kilograms in 1923). In 1922, 8,000 kg. of quinine were imported; in 1923, 12,000 kg.; in 1924,

* Previous papers on medical and scientific work in Soviet Russia by Dr. Horsley Gantt were published in the BRITISH MEDICAL JOURNAL in 1924: I, A Review of Medical Education in Soviet Russia, vol. i, p. 1055; II, Hospitals and Health Conditions, vol. ii, p. 356; III, Scientific Work, vol ii, p. 533. The first part of section IV, on "Change in type and incidence of disease," was published on August 14th, 1926, p. 303; Part II of this section was commenced on October 23rd (p. 747) and concluded on October 30th (p. 802). Part I of Section V was published on January 29th, 1927 (p. 198), and Part II on February 5th (p. 244).

† Narkomzdrav = official abbreviation for Narodny Kommissariat Zdravoochranenia (People's Commissar of Health).

‡ Tsik=abbreviation for Tsentralny Ispolnitelny Komitet.

60,000 kg.; but, according to Dr. Dobreitzer, four times this amount was needed.

The physico-therapeutical section of the Narkomzdrav was established in 1924. Dr. N. S. Zvonitsky, its chief, described its work to me as follows:

"During the war four physico-therapeutical institutes were built, but now we have over a hundred, and in the next two years we plan to build fifty more. We have received one million roubles from the central Government for this, and we shall receive three times this amount from the local governments where they are erected. Three million treatments were given in 1924. Our work is chiefly with the factory employees. In villages where we have no institutes we are beginning to teach the peasants to make use of natural agencies, as sun and air baths. The plan is being evolved by a central commission in Moscow for the whole of the U.S.S.R."

Dr. N. Kishkin, formerly Minister of the Interior under Kerensky, and now chief of the health resorts for the whole of Russia, said (1925) of his work:

"After the revolution we have many more diseases in Russia than formerly, and diseases that we never had before. The order of occurrence of these in our sanatoriums is: tuberculosis, bone diseases, nervous diseases, mostly functional, and stomach diseases. During the famine we had markedly fewer stomach ailments than now. The occurrence of syphilis this summer (1925) in our health resorts was 1.1 per cent. of the total number of patients—a decrease over previous years.

"We are doing ten times as much prophylaxis as before the war, through our tuberculosis and venereal institutes and dispensaries. We are doing less treatment because of the lack of drugs, equipment, and money. But the work is progressing. Although we have had workers in our sanatoriums for four years, we have had this year for the first time many thousands of peasants, and will have more next year." [The sanatoriums have been almost exclusively for workers and Communists, who receive maintenance free of charge.] "Many of our palaces are now turned into sanatoriums."

When I asked him about the relative position of scientific work in his department, he said:

"We formerly had no commissariat for health and no scientific work in the sanatoriums. For two years scientific institutes have been attached to the health resorts. There are central parent institutes in Moscow, where laboratory specialists work during the winter in conjunction with our therapists, planning the work for the summer. There are balneological, hydrological, and climatological sections at work. Before the war the sanatoriums were private, and the best doctors did not have charge of them; now the foremost surgeons and physicians are sent from Moscow, Petrograd, etc., during the summer to carry on the work."*

Care of Youth: Athletics.

After the revolution, children's homes, intended to care for the entire child population, were instituted, but these have been abandoned, so that there remain only homes for certain organizations, such as those for the orphans of peasants and workmen. Their condition is remarkably good compared to what it was when I visited them three years ago (1922-23). Besides the drilling in Marxism and antireligious formulae, the inmates are being taught personal hygiene and given systematic scientific instruction. This type of institute is entirely new in Russia.

In old Russia there was a lack of almost every form of sport. In the short space of three or four years its development has been phenomenal; athletics are now general in the large cities and institutes, and are spreading all over Russia. I have seen in villages two thousand miles away from the great centres boys playing football; and in the large cities great numbers of boys and girls engaged in football, games, rowing, swimming, and foot races—many more than there were two years ago.

The Highest Soviet of Physical Culture is under the control of the Narkomzdrav and of the Narkompross (Department of Education). It has chargo of physical culture in Soviet Russia. Mr. H. A. Anderson, of the European Student Relief, who has been responsible for the introduction of physical culture in the universities, has given me the following account (October, 1925):

"Physical culture is compulsory (on paper) in every school, from the lowest to the university, but is not carried out on account of the lack of funds, leaders, and programme, except in the large cities. In the whole country there is not a modern gymnasium, an indoor track, or an indoor public swimming pool.

"At first the Soviets allowed no competitive games, and tried to make the gymnasium supreme over sport, to agree with Marxian politics; however, this was impracticable, and now competitions predominate. There are two schools (Moscow and Leningrad) for training teachers of physical culture, with 600 students. The best physical culture is being done in the factories, where gymnastics is more general than in American factories, though not so well conducted as in the best American. School gymnastics are as yet poorly organized. Courses for physical culture are now, for the first time, conducted in Russia. One can judge of the progress of athletics by the record of the Russian soccer team, which ranks among the best three or four in the world, although this game was almost unknown in Russia six years ago. Other sports, however, have not developed so remarkably."

Propaganda.

One of the most successful efforts of the Narkomzdrav has been its propaganda for personal hygiene and against disease. I have seen placards of exhortation, not only in all public places, trams, etc., but in the reading rooms in small villages; and in the newly established peasants' and workers' clubs there are pamphlets and books on hygiene and infections. Several cinema films of educational and scientific value have been worked out. Among those which I have seen are "Abortion," explaining the dangers of irregular abortions; "Rejuvenation," explaining the Voronoff and Steinach operations; "Conditioned reflexes," dealing with the work of the Pavlov laboratories. These are shown to the general public. They contain scenes which, though entirely represented from the scientific point of view, would not be permitted in America—for example, full details of the birth of a child, sexual intercourse in animals, lunatics, etc. This shows both the naïveté and the freedom from prudery of the Russian mind.

Dr. Semashko, in commenting on the work of the Narkomzdrav to me, made the following observations: The present bad health conditions are largely the result of the lack of education dating from the imperial period and the effects of the famine. Prophylaxis by educating the people, which is one of the cardinal principles of the public health work at present, was forbidden under the rule of the Tsar. Trachoma and other such diseases were not combated then; there were no laws regulating working hours, nor rest homes for mothers, nor participation of workers in public health matters as at present, nor dispensaries. The death rate is now below that of 1913; infantile mortality, which was higher in Russia than in any other European country, has diminished from 25 per cent. before the war to 12 per cent. in Leningrad and 13.7 per cent. in Moscow; health officers are being sent into the villages; abortions, though legalized, are regulated, and are fewer than in other countries; there are now 1,699 country medical stations; against 1,338 before the war; the average radius of a doctor's practice is now 11.2 km. compared with 13.1 km. before the war; the Soviet Government gave 10,125,000 roubles in 1925 for the construction of hospitals and public health work. The campaign against prostitution illustrates the general trend of the work. "The battle against this social evil is against prostitution and not against the prostitutes. It proceeds on two lines: first, the relief of the unemployment of women and the prevention of vagrancy among women and children, and secondly, against houses of prostitution and their proprietors."*

CONCLUSION.

As a matter of historical interest I have described the past life of the Russian scientist. As regards the future, I have quoted the opinion of leading scientists both pro and con.

Scientific working conditions as well as general living have gradually improved during three years: for the last year there has been a marked improvement. There is no doubt in my mind, after nearly four years of intimate acquaintance with Russia, that the Soviet Government desires in every way to aid science. Its attitude, though coloured by the enthusiasm of the officials for Marxian politics, is comparatively liberal and generous, and is becoming more so. Though the Government is at present in financial straits, funds allotted to scientific work are being increased. There is a question, however, as to the extent to which their methods will produce practical results, in view of the

* The total number of patients at the health resorts is now less than before the war, but this is attributed to the need of repairs and the lack of money of the individual. Most of the beds are occupied by Government officials, members of unions, etc., whose expenses are paid by the Government or unions.

* The account in the above paragraph is derived from personal interviews with Dr. Semashko, and also from the *Weekly News Bulletin* of the Society for Cultural Relations with Foreign Countries.

changed living and social conditions under which scientists have to work. They are now treated with favour, and though they have suffered it has not been on account of any direct action against them. Their present economical condition compares favourably with that of other countries, if one makes allowance for the difference in the standard of living in Russia. While there has been deep gloom and pessimism as to the future of science in Soviet Russia, there seems to be a slowly growing optimism.

The newly organized public health department—the first worthy of the name in Russia—has shown interesting and energetic developments under the able leadership of Dr. Semashko. The extreme conditions under which it has had to work make difficult a judgement of its efficiency.

In the next (and concluding) article of this series I shall give details of the work of some of the scientists of Russia.

TUBERCULIN IN THE PROPHYLAXIS AND TREATMENT OF TUBERCULOSIS.

THE control of an infectious disease may be attempted in two ways: first, by exterminating the germ which causes the infection; secondly, by immunizing, or raising the resistance of, potential sufferers from the disease. In practice both methods are usually carried out in a large number of infectious diseases. Thus in typhoid fever the system of notification, isolation, and disinfection aims at destroying the bacillus, and so preventing the spread of the disease; while antityphoid inoculation is designed to prevent exposed persons from being infected. Similarly with small-pox, in which the object is to render the whole community insusceptible; but in the event of a case occurring measures are taken for stamping out the freshly introduced germ. It is, perhaps, failure to distinguish between these two processes which has prevented victory in the various crusades against tuberculosis. What are called tuberculosis schemes are mainly concerned with an attempt to exterminate the tubercle bacillus. It is not far off half a century since Koch discovered the tubercle bacillus. With the recognition of the infectiousness of tuberculosis battalions of sanitary forces have been thrown into the attack. The main objective of all these forces has been to destroy the tubercle bacillus wherever found, or at least to confine its ravages to the infected. The ubiquity of the bacillus has stood in the way of the success of these offensive measures; and it is still possible to maintain that defensive measures of immunization are the true way to victory.

Modern procedure in dealing with tuberculosis consists in notification, sanatorium treatment, dispensary supervision, the establishment of colonies, disinfection, and the examination of contacts. Subsidiary measures are concerned with the milk and meat supply. The object of all these measures is to prevent the dissemination of the tubercle bacillus. They have had some success, but it is very far from being complete; so widespread is the disease that many doubt if it ever can be; and not a few experts in the disease hold that if the measures were successful the result would be a community intensely susceptible to chance introduction of infection. If they are correct it would follow that the only way to check the ravages of tuberculosis must be by some form of immunization, that the disease must be fought on lines similar to those which overcame small-pox, though the conditions in tuberculosis may not render necessary universal vaccination. But it seems evident that any scheme must have regard to the cure of persons already suffering from chronic tuberculosis, since they may disseminate the infection.

TUBERCULIN IN DIAGNOSIS AND TREATMENT.

When Koch first prepared his tuberculin it was with the idea of curing actual sufferers from tuberculosis. Later its use was extended to diagnosis, especially in cattle. The unfortunate results in early days in the human being prevented its adoption as a routine means of treatment. Nevertheless, tuberculin or methods based on the theory of its action have continued to find supporters, and the possibilities of some such method as a preventive procedure should not be neglected. At present there are at least three methods of treatment in existence for definitely raising the resistance to tuberculosis: vaccination with the bacillus by the method devised by Calmette and Guérin, applicable only to the newly born; the Spahlinger method, which has attracted a great deal of public attention, but has not yet been thoroughly tested by competent and impartial observers; and the tuberculin treatment at dispensaries, advocated especially by Dr. Camac Wilkinson. There is, of course, a preventive side to tuberculosis schemes, and general public health administration, by raising the general health of the people, and presumably, therefore, their resistance to tuberculosis, by better housing, better food, and better hygiene, must have had a considerable effect. Moreover, it has within its range the examination of contacts, by which means it is hoped to detect early cases and prevent the development of the disease. But notwithstanding the undoubted value of these measures, the fact remains that in many instances, however early the disease is detected, and however thorough the hygienic measures adopted, the patient goes from bad to worse, and treatment is of no avail.

THE SCIENTIFIC ASPECT OF TUBERCULIN TREATMENT.

We propose to state the views of Dr. Camac Wilkinson, not because we have any conclusive evidence that his treatment is of any more value than other forms of treatment, but because they form a connected and ingenious theory of the disease which, if true, should be helpful in research. Moreover, although they do not necessarily involve preventive immunization of the whole community, they contain a suggestion that prevention may be aided by rendering sufferers from the disease less dangerous than ordinary hygienic measures can make them.

According to Dr. Camac Wilkinson, acute tuberculosis occurs mainly in two classes of people—in children under 2 years of age, and in adults who have never been infected at all. In both cases the disease is very severe and is nearly always fatal. Very many people, however, are affected mildly, possibly through milk, after 2 years of age, but they have been able to overcome the disease, and they have done so by encysting the tubercle bacilli in a fibrous capsule. The process renders such persons immune to mild doses of infection, so that the majority go through life without any further manifestation of the disease. Dr. Wilkinson, we gather, holds that without this encapsuled focus there would be no immunity for them; but if by chance they meet with some massive source of infection at a time when their resisting power is lowered, they are very liable to become infected. These are the persons who provide the vast bulk of the cases of chronic pulmonary tuberculosis. Having originally had an infected focus they are comparatively immune, and do not suffer from acute forms of the disease, but meeting a massive infection when their resistance is lowered they become chronic tuberculous cases.

Dr. Wilkinson's next proposition is that tuberculin enables a diagnosis to be made at a time when physical signs are practically absent, and also when it is still doubtful whether the case is one of acute or chronic tuberculosis. According to his view a positive reaction to tuberculin indicates the presence of living tubercle bacilli in the body. In a patient who has reacted positively, a lessened reaction on later inoculation shows that the tissues are winning; an increased reaction indicates that the bacilli are winning. No reaction to tuberculin indicates that no bacilli are present. Consequently tuberculin, he holds, not only shows whether tubercle bacilli are present or not; it also discriminates between cases that are progressing and cases that are retrogressing, and is the only means of distinguishing the early stages of acutely fatal forms from the early stages of chronic forms of the disease. He believes, however, that tubercle bacilli cannot survive long in fibrous tissue.

THE USE OF TUBERCULIN IN TUBERCULOSIS.

Dr. Wilkinson's next assertion is that tuberculin is the best treatment in forms of tuberculosis which are amenable to any treatment. The therapeutic effect of tuberculin, he

says, is to favour fibrosis, which is the only process that can lead to anything that can be described as cure. The production of fibrosis leads to the disappearance of tubercle bacilli from the sputum; those that have not perished have become encysted, and so are rendered harmless. Consequently tuberculin treatment can be applied at a dispensary, the diseased process can be arrested in individual patients, and the bulk of them rendered free from danger to others; and the enormous costs of present tuberculosis schemes can be largely curtailed. Infectious cases are, he maintains, thus converted into non-infectious, and the risk of massive infection in the family is minimized or removed.

The point in Dr. Wilkinson's thesis which may prove most difficult of acceptance is his statement that to produce immunity in tuberculosis it is necessary that a focus of infant infected under 2 years of age almost invariably contracts an acute tuberculosis which is fatal. But after 2 years of age a mild infection may be contracted, the bacilli may become encysted, and the presence of this encysted focus of the disease will render the child more or less immune, but not completely so. If the tubercle bacilli, says Dr. Wilkinson, are destroyed in the primary stage, as probably often happens especially in the chronic forms of the disease should exist. According to Dr. Wilkinson an infection may be contracted, the immunity slowly disappears and reinfection may occur, but not in an acute form. In these cases in middle life a massive infection may overcome such immunity as remains, and the patient may become an example of the common form of chronic pulmonary tuberculosis. It appears, therefore, that in Dr. Wilkinson's opinion a mild infection after 2 years of age may either be completely cured or may leave a fibrous encysted focus. In either case the patient is fairly well protected from acute forms of tuberculosis; but in both he is susceptible to the chronic form of the disease if exposed to massive infection. The completely healed person will not react to tuberculin, while a reaction is obtained whenever an encysted focus is present.

Dr. Wilkinson regards the disuse of tuberculin in the cure of the disease as due to errors in its administration. He asserts that he has never seen any harm caused by tuberculin when properly administered; and, as we have indicated, he regards it as by far the best and least costly treatment. Dr. Wilkinson's method of treating his patients is to begin by injecting a dose—generally 0.0002 c.cm. of T.A.F. or T.A.—for diagnostic purposes. Any rise of temperature to 100° F. or over, coupled with a skin reaction and other special symptoms following the dose, is regarded as conclusive of the existence of living tubercle bacilli in the body. If the temperature rises to less than 100° F. further diagnostic doses of 0.001 c.cm., 0.005 c.cm., and 0.01 c.cm. are given. Dr. Wilkinson asserts that in thirty years' constant use of tuberculin he has never seen a bad effect from one or several test doses. On many occasions, on the other hand, he has been able to prove the existence of tuberculosis in people who had been regarded as free from the disease; while in others a previous diagnosis of tubercle has been shown to be erroneous.

When satisfied that the diagnosis of tuberculosis is correct, Dr. Wilkinson proceeds to treat the patient with tuberculin, beginning with quite small doses, increased at intervals of four to six days, until as much as 1 or 2 c.cm. are injected. The speed with which the dose is increased depends upon the reaction shown by the patient, who is taught to keep a record of his own temperature. The patient's weight, to increase of which Dr. Wilkinson attaches great importance, is recorded at each visit to the dispensary. After a course of treatment, lasting some months, patients are advised to present themselves a year later for further test doses.

WHAT IS IMMUNITY TO TUBERCULOSIS?

It is not, however, with Dr. Wilkinson's claims to successful treatment of individual sufferers from tuberculosis that we are most concerned. Such claims are made by everyone who treats tuberculosis, yet tuberculosis persists. The questions which seem to be of importance are: First, does tuberculin cause fibrosis, and thereby shut off foci of infection? Secondly, if so, does it produce results sufficiently effective to render unnecessary some of the costly tuberculosis schemes? Thirdly, to what extent can its use be described as preventive? We gather that no claim is made that tuberculin can be used as a vaccine for immunization against tuberculosis comparable to the vaccination by attenuated living bacilli, for which good results in infants are claimed by Calmette. It appears, however, to be a fact that tuberculin is used in treatment, even in some sanatoriums; it seems to be very difficult to obtain definite statements as to the results; and it is clear that the questions we have asked can only be answered after proper investigation. In 1920 the Medical Research Council was asked by the Ministry of Health to investigate the claims made by Dr. Wilkinson, and Drs. G. T. Western, L. S. T. Burrell, and A. S. MacNalty were entrusted with the task. The report of these observers was at first regarded as confidential. But in the summer of 1923 Dr. Wilkinson published a pamphlet, entitled *The Tuberculin Dispensary for the Poor*, in which he criticized the report severely, and complained that the observers had made serious misstatements about his treatment, and had not given sufficient time to the investigation of his methods and his cases. In reply to this pamphlet the report was published in full in the *Lancet* on November 3rd, 1923.

In matters of scientific interest, especially in those which may have large public importance, it is unfortunate should prejudice or intolerance of criticism be allowed to affect the issue. The main conclusion of the observers was that "the method of tuberculin administration advocated by the Tuberculin Dispensary League does not appear to have claims over other methods of treating tuberculosis, either with or without tuberculin, which would justify its general adoption." There is no reason to doubt that the observers arrived at this conclusion after due deliberation on the material offered to them; and, from the point of view from which they investigated, it is quite possible that the conclusion was legitimate. What may be doubted is whether the observers had in mind the object which, perhaps, is alone of any real value to public health.

Let us briefly recapitulate the argument. All tuberculosis schemes are more or less ineffective in exterminating tubercle. We have ventured to suggest that in most schemes the objectives of extermination and immunization are not clearly distinguished. Among the schemes having an immunizing objective may be placed Dr. Wilkinson's. He alleges that large numbers of people are immunized in childhood, probably by bovine infection. This immunity is liable to break down later on when a patient is exposed to massive infection. If this occurs he proposes again to close the open tuberculosis by means of tuberculin, which promotes fibrosis. In doing so he asserts that he renders the patient less liable to infect others. The observers from the Medical Research Council appear to have confined their attention solely to the percentage of cures obtained by Dr. Wilkinson's treatment. They do not seem to have made any criticism of the scientific value of Dr. Wilkinson's views; and they made no comparative estimation of the merits and costs of the treatment. They found that the percentage of cures was no larger than that obtained by other forms of treatment. The question at once leaps to the mind, if the cures are the same and the costs to the community and also to the individual are less, what reasons are there for preferring the more expensive treatments to the cheaper? The observers do not answer this question, unless it is by leaving us to infer that tuberculin as administered by Dr. Wilkinson appeared to them to be useless, although they do not go so far as to say so. Indeed, they cannot have come quite to this conclusion, since they state that occasionally individual cases seem to derive distinct benefit from tuberculin treatment. They found that Dr. Wilkinson succeeded in immunizing his patients to large doses of tuberculin, but that there was no evidence that he immunized them to tuberculosis. Yet in the next paragraph, referring to patients who had had "hygienic" treatment as well as tuberculin, they say that early recognition and putting the patient under hygienic conditions rank as *equal* with, or as more important factors than, tuberculin in the arrest of the disease. We have confessed that we had no evidence that Dr. Camac Wilkinson's tuberculin

treatment is of any more value than other forms of treatment in individual cases of tuberculosis. What we cannot gather from the report of the Medical Research Council's observers is whether it is of less, or no, value. Above all we find in that report no definite challenge to the views on tuberculosis held by Dr. Wilkinson.

Seeing that offers of assistance have been made to M. Spahlinger for the purpose of testing his views, which, so far as we understand them, have a certain general resemblance to those of Dr. Wilkinson, we think it would be justifiable to ask the Medical Research Council or the Ministry of Health to undertake further investigation of the tuberculin dispensary treatment, especially in its scientific aspect. The questions to which answers might be sought are: Is it true that tuberculin as administered by Dr. Wilkinson produces no ill effects? Does tuberculin cause fibrosis around tuberculous foci? If so, can the effect be produced in a sufficient number of patients to lessen the dangers of infection to others? Is tuberculin of use for diagnosis in the human being? If the answer to these questions is in the affirmative, the final question is whether the use of the treatment is sufficiently effective to relieve the country of some of its burdensome expenditure on tuberculosis. If the answer to the questions is negative, the tuberculin dispensary patients might profitably be directed to other forms of treatment.

PNEUMONIC PLAGUE.

EPIDEMIOLOGY, DIAGNOSIS, AND TREATMENT.

A Treatise on Pneumonic Plague[1] by Dr. Wu Lien-Teh is a valuable recent addition to the series of publications issued by the Health Organization of the League of Nations. Its author, who is a graduate in medicine of Cambridge, is the greatest living authority on this form of the most devastating of epidemics. The arrangement of the work is excellent; full attention is paid to theoretical ideas and explanations, each tested by carefully planned and admirably executed scientific investigation, and followed by a cautious summing-up of the evidence and an unbiased statement of the conclusions which may legitimately be drawn. To each of the eight chapters is appended a full bibliography; in the bibliography to Chapter I, on the history of pneumonic plague, 561 references are given. This chapter is of great interest; in it are discussed the epidemics which have been, often on insufficient grounds, regarded as plague, and it is concluded that the first definite reference to the disease dates from the time of Justinian (A.D. 542). There is a table giving the incidence in different countries from the beginning of the fifteenth century (by mistake called fourteenth in the heading) to the present day, and another, even more important, stating the various places all over the world where outbreaks have occurred, naming the rodent and other mammals involved in the epizoötic, and their principal fleas, and stating the incidence of pneumonic plague. The author shows that in the vast majority of epidemics the earliest cases are bubonic, but that pneumonic cases occur with greater frequency at the beginning of pandemics. The first bubonic cases become quickly complicated with secondary pneumonia and appear clinically as if they were primary pneumonic plague. "Only at autopsy can the primary bubo be found."

The outbreak on s.s. *Calypso* in 1906 appears to have been at first of true pneumonic type, and in this instance rats and mice killed by fumigation were examined with negative results.

Chapter II deals with plague in wild rodents and its spread to man. The countries which the rodents inhabit are enumerated, with histories of outbreaks among them, and their distinguishing features, modes of life, the existence in them of natural plague and experimental infection, are discussed. Appended to this chapter is a list of those rodents which are known to suffer from spontaneous plague, the countries in which they occur, and the references to the literature where the record can be found.

The epidemiology of pneumonic plague is considered in three main sections—rise, spread, and decline. The first question which occurs is one that has not yet been fully answered: it has to do with the origin of pneumonic plague epidemics; they do not arise directly from epizoötics, but from human cases with secondary lung involvement. They may originate from bubonic cases by action of "extrinsic" factors, meteorological and social. This, however, does not explain the frequency of pneumonic cases in newly invaded areas at the start of an epidemic; examples of this are afforded by the black death, and by the pandemics in India, Japan, and elsewhere; it may be that climatic conditions enhance the susceptibility of the lungs to disease while bad social conditions impair individual resistance. Other explanations offered are that there is an "intrinsic" factor, that there are two strains of the bacillus (not confirmed by the Plague Commission), that there may be a special virulence, or a mixed infection, or, lastly, a "pneumotropism" of bacilli; in favour of this last there is some evidence. The relation of special flea-vectors is also considered; the *Xenopsylla cheopis* is said to account more for bubonic, the *Pygiopsylla ahalae* for pneumonic attacks; but this matter is complicated by the question of the species of rodent involved and the characters of the corresponding epidemics. Probably the human factor is the most important, because pneumonic plague usually spreads directly from man to man, and not by the intermediation of the flea; when dealing with the pathology of the disease and primary pneumonic plague in animals the author shows, moreover, that all are not equally susceptible to respiratory infection. After a description of the morbid anatomy, bacteriology, and diagnosis there follows a discussion of the site of entry, which is shown to be the deep portion of the respiratory tract.

Chapter V, on the clinical features and diagnosis, amplifies the statements found in modern textbooks, and the next chapter clears up several dubious points, and tells all that is known of the infectivity and immunity of this form of plague. It is shown that patients are non-infective in the very early stage, because cough and expectoration are absent, that even fairly close contact may not suffice to communicate infection, that the bacillus has a poor resistance to drying, and that, on this account, the evidence for dust-borne infection is weak. If the temperature is sufficiently low, dead bodies remain infected for considerable periods, even through the winter. There is no racial immunity or susceptibility; spread depends on the living conditions—bad ventilation, overcrowding, habits of indiscriminate spitting, etc. The possibility of carriers must not be forgotten; they probably play a very limited part in the spread of pneumonic plague.

Therapy and prophylaxis occupy the last two chapters; the penultimate dealing with personnel, the last with general prophylaxis and the management of epidemics. The value of serum, vaccines, and a combination of the two is discussed with sound and impartial reasoning. The management of epidemics is considered from the two aspects: Measures *within* the infected area, such as detention of cases, disposal of patients, management of contacts, evacuation of buildings, disinfection, disposal of corpses, etc.; measures *outside*, such as the establishment of a cordon, control or stoppage of traffic, and other like matters, while publicity, propaganda, and educational campaigns are not omitted.

Appended to the treatise are some good plates of rodents and of patients, microphotographs of the tissue changes set up, and stained sections of them; pictures of masks and clothing, ambulances, etc., while, as a frontispiece, there is an excellent reproduction of a plague lung. The bibliographies, as already stated, are very full; so is the table of contents, but this does not quite make up for the absence of an index. This is not only the best book on the subject of pneumonic plague which has appeared up to the present, but it will probably remain the standard treatise for many years to come.

HUNTER AND LISTER.

THE task set before a Harveian or a Hunterian Orator nowadays is no light one. His many distinguished predecessors must seem to him to have covered the ground so thoroughly as to leave little scope for saying anything new. Sir Berkeley Moynihan, the latest Hunterian Orator, nothing daunted by the difficulties of the situation, has drawn a parallel between John Hunter and his successor at a century's interval, Joseph Lister, which is of the greatest interest. If, as Timothy Holmes said in 1893, on the occasion of the centenary of Hunter's death, he was the "greatest man indeed who ever practised surgery," Sir Berkeley Moynihan was surely justified in his claim for Hunter and Lister together that they were the two greatest surgeons the world has ever known. Despite the deficiencies of his early education, Hunter was the first scientific and philosophic surgeon who approached his subject, as Lister did, by the way of physiological and biological experiment and investigation.

It is fitting that the latest panegyrist of these two great men should in himself fulfil Sir Jonathan Hutchinson's ideal of a surgeon as "a physician who operates," and should be so eminently well qualified to take a broad philosophic view of the progress and prospects of surgery. It was a happy inspiration which led him to couple in his oration these two heroes of modern surgery—the young Scot who left his native Lanarkshire in 1748 to join his celebrated brother William in London, and to become successively pupil, house-surgeon, and surgeon at St. George's Hospital, and the young Englishman who, like him, but with a difference, left his Alma Mater, University College, to become house-surgeon to Syme in Edinburgh, almost exactly a century after Hunter had filled a similar office in London. Both were natural philosophers and physiologists before they were surgeons, and both made revolutions in practice and founded schools of surgery. In his lifetime Hunter's fame was by no means commensurate with his merits, and only the elect realized his greatness: for his gift of exposition was poor, and he never acquired the power of clarity of expression. Ill health impaired his vigour and no doubt affected his temper for the last twenty years of his life, during which he felt the effects of that experiment which "rendered him, in the words of Sir D'Arcy Power, "a martyr to science," and terminated his existence before he could receive his due meed of fame. Abernethy, who might be called an apostle of Hunter, and knew him well and admired him, wrote of him: "I was acquainted with Mr. Hunter at a period of his life when he must have greatly interested anyone who duly appreciated the results of his talents and labours, or who had any sympathy for the highly susceptible mind of genius, rendered still more so by excess of exertion and the perturbed feelings incident to bodily disease. He seemed to be conscious of his own desert, of the insufficiency and uncertainty of his acquirements, and of his own inability readily to communicate what he knew and thought."

Lister, more fortunate in his intellectual equipment and training, and enjoying a much longer span of life, lived to see his teaching triumphant over prejudice, ill-judged opposition, and ridicule, until when he died, full of years and honours, the Council of the Royal College of Surgeons of England passed that worthy resolution in which it is truly stated that "He raised Surgery from a dangerous and precarious practice to a precise, safe, and beneficent Art, and in doing so, his name became renowned throughout the civilized world. . . . His gentle nature, his deep compassion, his imperturbable temper, his resolute will, his indifference to ridicule, his tolerance of hostile criticism, combined to make him one of the noblest of men." To adopt the orator's striking metaphor, Lister has erected a great, complete, and permanent bridge over which we have all passed to triumphant successes in surgery. Hunter was forever building bridges, ambitious in design, firm in their foundations, but always left unfinished, as witness his experiments in embryology, in the transplantation of life in the tissues, and organs, in the preservation of life in the tissues, and on the sensitive plant, to mention only a few of his researches. Some of these bridges are being completed, and others doubtless will be, when the foundations laid by Hunter will be found sound.

If to-day the amount of ground covered by the ancillary sciences is so vast that no man can hope to possess an up-to-date knowledge of physiology, pathology, chemistry, physics, and surgery, as was possible in Hunter's day, then the surgeon must more and more often and more fully take into his counsels the experts in these branches of knowledge. Let no man think that in so doing the gain is likely to be all on one side. The pathologist and the physiologist may learn much from what the surgeon has to show them of the pathology of the living, on the importance of which Sir Berkeley Moynihan has elsewhere and at other times insisted, and on which he again insists in this oration. As he pointed out, Lister—although he did not use this phrase—well recognized the importance of this part of the subject when he devoted so much industry and intelligence to the study of inflammation. Surgery, in the orator's opinion, is a great weapon of research. Operations undertaken and conducted solely in the interests of the individual patient have resulted incidentally in valuable additions to our knowledge of normal anatomy and physiology, as well as of pathology, which could hardly have been gained by any other means.

We all hope we may flatter ourselves that we of the twentieth century have more open minds, freer from prejudice and with a wider outlook, than our predecessors of the nineteenth; yet it is probable that the surgeons and pathologists of the middle of the last century laid a similar flattering unction to their souls, although there are those now living who remember how hardly and how slowly Lister's principles won recognition in London. Their value once demonstrated, it might have been thought that they would have found ready acceptance. But it was not so. These principles were arrived at by Lister and by him alone. The work of Pasteur and his triumphs in general pathology were well known in this country, but Lister alone saw their bearing upon the problems of suppuration and sepsis, and applied Pasteur's discoveries in the hospital ward. This reflection should make us humble, and incline the hearts of the younger generation to follow the advice of Sir Berkeley Moynihan to profit by the great spiritual legacy left by such men as Hunter and Lister, and to avail themselves of that surgery which he describes as the mo-

powerful weapon of research. We look forward, with the orator, to the day when preventive surgery as well as preventive medicine shall have rendered unnecessary much of what is now familiar to us as surgery, and when our weapons of war—or rather, those of our successors and descendants—shall be laid aside as no longer needed. Sir Berkeley Moynihan's eloquent peroration must inspire all who read it with a spirit of hope and faith in the future of our art.

THE VOLUNTARY SYSTEM IN MEDICINE.

SOME prominence has been given in the daily press to a speech by Sir Kingsley Wood, Parliamentary Secretary to the Ministry of Health, delivered on the occasion of the opening of the new buildings of a convalescent home at Worthing. The speech, along with other interesting matter, contained two declarations of policy which are worth noting. Speaking with some appearance of authority (though in such matters it is difficult to be certain what amount of authority appertains to the utterances of a subordinate member of the Government), the Parliamentary Secretary said with regard to the hospital question that "the Government stood firmly by the voluntary system, and would do everything it could to encourage voluntary organizations and hospitals"; and he went on to declare that "the Government's policy was wholly opposed to the creation of a State medical service. It would not be in anybody's interest to take the work now being done by the medical practitioners of the country and put it into the hands of whole-time public servants."

The main reason for which these declarations will be welcomed by the medical profession is not that they remove any apprehension of an early and radical change of system in public health and hospital organization. No such apprehension exists. The defences against any such frontal assault on existing methods are secure. As Sir Kingsley Wood himself said: "One of the best signs of the time was that during the last two years the voluntary hospitals had demonstrated their vitality and their hold on the people of this country." These hospitals have so established themselves in the hearts of all classes in the community, givers and receivers alike, that any direct and deliberate attempt to change fundamentally the system of their governance and management would be emphatically condemned by public opinion. A similar statement is equally true with regard to any suggestion to impose upon large numbers of people in this country a system by which they would be provided with medical advice and treatment through whole-time State or municipal doctors rather than by means of private practitioners of their own choice. As Sir Kingsley Wood again said, "Nothing would be gained by such a course, and much would be lost."

Changes and extensions are, however, in progress or in contemplation in connexion with various health and hospital services. Some of these changes and extensions are urgently necessary, and will receive the whole-hearted support of the medical profession. The danger is lest, in this process of reform and enlargement, anything shall be done insidiously, almost unwittingly, to weaken the principles and traditions of voluntary hospital management and of private medical practice, which are now by common consent recognized as being of such vital importance to the health and social life of the nation. In changing the character or position of Poor Law hospitals, and in encouraging or sanctioning the extension of municipal or county hospitals of various kinds, the relation of these institutions to the existing voluntary hospitals is of the utmost possible moment. In making increased communal provision for the giving of medical advice and treatment to certain sections of the population, whether mothers and babies, school children, or dependants of insured persons and others in like economic position, the decision as to whether this shall be effected by municipal clinics and treatment centres which are, or have a tendency to be, staffed by whole-time medical officers, or shall be brought about by an insurance or other system in which the best features of purely private practice, including an effective freedom of choice of doctor, can without difficulty be incorporated, is perhaps the most vital of choices presented to the profession, the social reformer, and the politician. On professional and on public grounds alike there should be no hesitation in making it. The one method leads insidiously, but scarcely less certainly, to a whole-time State clinical service; the other can be used effectively to maintain all that the medical profession holds most essential and all that the public has learnt most to appreciate in its relations with members of the profession. It is because the declarations of the Parliamentary Secretary to the Ministry of Health have such an important bearing on these questions that they will most be welcomed; and they are of the greater importance if they can be taken as an official assurance that the principles thus enunciated will be applied by the Government in any legislative and administrative measures that it may propose or take.

DIVERTICULOSIS AND DIVERTICULITIS.

SEVEN years ago the Subsection of Proctology of the Royal Society of Medicine staged what is believed to have been the first set discussion on the subject of diverticulitis. The meeting was extremely well attended, and its immediate result was that diverticulitis ceased to be known merely as a sort of occasional by-product of the operating theatre or *post-mortem* table, but earned for itself a place in scientific medicine, with well defined symptomatology and pathology. But that discussion did more for medicine than merely to put diverticulitis in its proper place, for it set in train a series of investigations as to its causes, its early history, and its clinical course, of which only the last stage had previously been recognized and studied.

Last week the Subsection once again chose diverticulitis for discussion, and it soon became evident that the intervening seven years had been fruitful in results. Dr. Spriggs opened the proceedings by recounting the conclusions arrived at by himself and his colleagues at Ruthin Castle, and an international atmosphere was given to the discussion by the presence of the well known French surgeons Drs. Martel and Pauchet, both of whom addressed the meeting in fluent English, the latter supplementing his remarks by showing some of those splendid drawings for which his surgical contributions are so notable. Dr. Spriggs made it clear that the chief advances in our knowledge of diverticulitis are due to improvements in radiological technique, particularly as applied to the opaque enema, and he showed slides which had been taken from the same patient over a period of years in which it was easy to trace the progress of events from the early stage of multiple small diverticula to the final condition of chronic

inflammatory thickening of the bowel, leading to obstruction. It became evident from the figures and the x-ray slides how well founded was the suggestion that the term "diverticulitis" should be reserved for those cases in which secondary changes had become established. The much larger number of cases where secondary changes have not yet developed would then be classified as examples of diverticulosis.

When does diverticulosis become diverticulitis? This change is at once revealed by serial x-ray photographs following an opaque enema, and wherever inflammatory changes are occurring in the diverticula the normal peristaltic waves are lost—a fact readily demonstrated by superimposing one picture upon another and taking tracings. It appears to be agreed by all observers that, when once established, diverticulitis is always progressive, although a great deal may be done by careful treatment to delay the final complications of obstruction, pericolic abscess, and fistula. With diverticulosis, on the other hand, it seems that efficient medical treatment may avert indefinitely the onset of secondary changes, so that it is probable that increasing knowledge and experience will go a long way in the direction of diminishing the proportion of cases that come into the surgeon's hands.

Although, in a sense, the physician would appear to have it all his own way with diverticulosis and diverticulitis, it must not be supposed that surgery has stood still. Far from it; for as the nature and pathology of these interesting cases have become better understood, the surgeon has been able to develop his technique in such a way as to enable him to deal successfully with most of the complications that may arise when the early stages have been unrecognized or inadequately treated. Sir Charles Gordon-Watson, Mr. Mummery, Dr. Martel, and Dr. Pauchet all gave lists of cases in which a high degree of success had been obtained, and the latter described a most ingenious method of replacing by a piece of small intestine a portion of the descending colon excised for diverticulitis. It seems evident, however, that whereas seven years ago diverticulitis was essentially a surgical disease, it has now definitely come within the province of the physician, and that in future it is only his failures that the surgeon will be called upon to treat.

TESTS FOR DRUNKENNESS.

A good example of the work the British Medical Association does for the information, not only of the profession, but of the public—and in this instance for the better administration of justice—is afforded by the report on tests for drunkenness, which is published in full in the SUPPLEMENT this week. For several years a good deal of public attention has been aroused by the number of convictions of persons charged with drunkenness when driving a motor car, and a certain amount of apprehension was caused by the fact that in some of these cases, which were reviewed with the assistance of counsel, the decision of the magistrate was not sustained. In the autumn of 1925 the Association of Metropolitan Police Surgeons informed the British Medical Association that it had been considering the revision of the tests in common use, but had arrived at the conclusion that it would be better for the British Medical Association, which is representative of all shades of professional opinion, to take the matter up. The Council accordingly appointed a committee, containing some of its own members, two metropolitan police magistrates, and several police surgeons. It was well known that charges involving an allegation of drunkenness were also made in the police courts in a large number of other cases not connected with motor cars. The British Medical Association was concerned in two aspects of the position which had arisen: first, there was what may be called the clinical question—the diagnosis of drunkenness; secondly, it was aware that in a good many cases a regrettable conflict of medical evidence was disclosed. The committee, over which Major-General Sir William Macpherson presided, had from the first to take into consideration the fact that the symptoms produced by alcohol, as by other toxic substances, vary in severity, according to the size of the dose, and, possibly, the susceptibility of the individual. The mere fact that it was proved, or admitted, that some alcoholic liquor had been taken a short time before the occurrence of the circumstances which led to the charge was, in a country like this, where so many people are in the habit of taking alcoholic beverages, clearly insufficient. The committee studied the subject very thoroughly in all its aspects, and examined much of the voluminous literature which has grown up about it, including the practice and regulations in foreign countries. It examined also the tests in common use in this country to determine the fact that the accused person was "drunk," and came to the conclusion that there is no single symptom due to the consumption of alcohol which might not also be a sign of some other pathological condition. The committee attempted a definition of the word "drunk," which it considers "should always be taken to mean that the person concerned was so much under the influence of alcohol as to have lost control of his faculties to such an extent as to render him unable to execute safely the occupation on which he was engaged at the material time." The advice to the medical practitioner called in to such cases is that in the absence of any pathological condition a person may be declared to be definitely under the influence of alcohol if there is a smell of it in the breath or in the vomited matter, but only provided certain concomitant signs or symptoms are observed—namely, a dry furred tongue or excessive salivation, irregularities in behaviour, suffusion of the conjunctiva, coupled with an abnormal condition of the pupil, loss or confusion of memory, particularly for recent events, and of appreciation of time, hesitancy and thickness in speech, and tremors and errors of co-ordination and orientation. An interesting clinical observation which has been made by many police surgeons is that when alcohol in toxic quantity has been consumed the pupil reflex to ordinary light is absent, but that to a bright light the pupil will contract and remain contracted for an abnormally long time, indicating delayed reaction. The committee was not able to recommend the estimation, by analysis of the blood, urine, or cerebro-spinal fluid, of the amount of alcohol consumed. This is also the opinion of the Danish Medico-Legal Society, after consultation with the police. Such examinations are not practicable in the circumstance in which an allegation of drunkenness is ordinarily made. A medical decision must be reached within a short time, and the committee recommends that in ordinary cases any person accused of drunkenness should be able to rely upon being seen by a doctor, if he so desires, within half an hour of the time at which he is charged. After studying the procedure of the police in Great Britain, of the Royal Navy, and of the Army, and also in New Zealand, France, and the United States of America, the committee arrived at the conclusion that in order to obtain uniformity in the method of testing drunkenness some such form of certificate as that drawn up by the Danish Medico-Legal Society might with advantage be adopted when examining persons in this country. For particulars of the Danish method reference must be made to the report itself, where they are set out in an appendix. The Council of the Association has directed that the report should be printed separately and put on sale.

THE HUNTERIAN FESTIVAL, LONDON.

THE Hunterian Festival of the Royal College of Surgeons of England was held on Monday last, when the President, Sir Berkeley Moynihan, delivered the Hunterian Oration, which is published in the opening pages of this issue. Before the oration, at a private meeting of the Council, Princess Mary, Viscountess Lascelles, was admitted an Honorary Fellow of the College; she is thus the first woman to be placed on the roll of honorary Fellows, and the fourth member of the Royal Family whose name appears on that roll, the others being the King, the Prince of Wales, and the Duke of Connaught. She attended the oration wearing the academic costume of a Fellow. In the evening a dinner was given in the College Library, where a large company of guests was entertained. After the usual loyal toasts had been honoured and "The Memory of John Hunter" had been drunk in silence, the toast of "The Guests" was given by the senior Vice-President, Sir Cuthbert Wallace, who asked Viscount Lascelles to convey to Princess Mary the College's appreciation of the honour she had done it; she had thus set the seal of her favour on the action of the College in giving full rights to its women Fellows. In speaking of the guests he mentioned them in groups—the law, the arts, the public services, and the many members of the medical profession present. In conclusion he expressed the opinion that owing to the work of Lister the technical achievements of surgery had perhaps reached a limit, and that it would be necessary to turn away from the mere handicrafts of surgery to the collateral and ancillary sciences. Lord Riddell, who replied in a jocular vein, said that what the public wanted to know from the medical profession was, not what to avoid, but what diet to take in order to attain the intellectual eminence which he saw in so many of those around him. The toast of "The President and the Hunterian Orator" was given by Viscount Lascelles, K.G., who began by conveying a message from Princess Mary expressing her pleasure in receiving the honour conferred upon her that day. She looked upon it as setting the seal on the work she had attempted to do during the last six or seven years. She had begun her active career during the war, and had always been attracted to that part of social work which aimed at the alleviation of suffering. Lord Lascelles went on to speak of his long association with Sir Berkeley Moynihan in many movements in which they were both interested in the part of the West Riding where they both resided. The President, in an eloquent and moving reply, recalled how the family to which Viscount Lascelles belonged had consistently used its influence to promote the welfare of the Leeds Infirmary from the time of its foundation in the eighteenth century by the first Hey. He mentioned the succession of Heys as surgeons to the Infirmary and the high ideal possessed by the staff of that great hospital—an ideal which he had always endeavoured to maintain. The end of his own services to the Infirmary was approaching, but he had the satisfaction of feeling that he had helped to inspire his present colleagues, who would be his successors, and most of whom were his pupils, with the hopes for the future of surgery by which his own career had been actuated.

THE BRIGHT CENTENARY.

THE centenary of the publication of Bright's *Reports of Medical Cases*, the famous book which announced the discovery with which his name has ever since been associated, will be celebrated next July at Guy's Hospital. Richard Bright, who was born in Bristol in 1789 and graduated M.D.Edin. in 1812, took several opportunities which opened to him to visit many parts of Europe, including Iceland, and did not settle in London until 1820, when he was elected assistant physician to Guy's Hospital. He became full physician in 1824, and when he resigned in 1843 he was made consulting physician. As was stated by Dr. J. F. Payne in the *Dictionary of National Biography*, Blackall and Wells had pointed out that dropsy was in many cases connected with a special symptom—namely, that the urine was coagulable by heat, owing to the presence in it of albumin. But the two symptoms were not traced to their source until Bright, by his *post-mortem* investigations, ascertained that in all such cases a peculiar condition of the kidneys was present, and thus proved that the symptoms really were those of a disease of the kidneys. "The explanation," Dr. Payne continues, "once given seems as simple as putting two and two together, but the importance of the discovery is shown by the fact that no one before had suspected the kidney to be the organ implicated. It proved Bright not only to be an acute observer, but to possess the much rarer faculty of synthesis, which makes an observer a discoverer." The significance of Bright's synthesis was quickly understood in all parts of the world, and has perhaps rather obscured the fact that Bright showed his originality of mind in the description of many other diseases, especially those of the abdomen. Sir William Hale-White pointed all this out in *Guy's Hospital Reports* for 1921, and noted in particular that one book written jointly by Bright and Thomas Addison contained a description which Howard Kelly seventy years later said "could not be surpassed to-day" of the now common disease which in 1866 was named appendicitis by the late R. H. Fitz of Boston, U.S.A. Invitations to be present at the celebration have been accepted by many distinguished persons in all parts of the world, and the Royal College of Physicians of London will give a conversazione.

INDIAN PILGRIMAGES AND CHOLERA.

SIR LEONARD ROGERS'S recent paper before the Indian Section of the Royal Society of Arts on the forecasting and control of cholera epidemics in India was in part a recapitulation of the considerations he had addressed to the Royal Society of Medicine some months ago;[1] but he stressed more particularly the part played by fairs and pilgrimages in the occurrence of such epidemics. While deficient rainfall, he said, was a constant factor predisposing to cholera epidemics, the effect of the great pilgrimages could not be disregarded. His warning is timely, because 1927 is the year of the great Kumbh Hardwar fair, which takes place every twelfth year, and attracts pilgrims to the number of between one and two millions. The fair years of 1867, 1879, 1903, and 1915 were all marked by epidemic invasions of the Punjab from the endemic areas of the western United Provinces, and the Hardwar pilgrims were almost certainly the vehicle. In one of the fair years, 1891, the increased incidence was comparatively small, because the absolute humidity in that year was unfavourable to cholera spread. In other parts of India also pilgrimages and fairs were shown to be active agencies, as, for instance, in the dissemination of cholera over the Central Provinces from the surrounding areas, and in the Bombay Deccan. Discussing prophylactic measures, Sir Leonard Rogers said that much had already been done to diminish cholera in some of the large towns by the provision of good water supplies, but India was in the main a land of villages, and it would take centuries to improve village sanitation to the extent necessary to reduce materially the prevalence of this disease in India. A simple and effective measure, however, was available in anticholera inoculation. The numbers to be inoculated in any one district, even in the Kumbh year, would only be

[1] BRITISH MEDICAL JOURNAL, May 1st, 1926, p. 784.

a few thousand, and with a little organization every dispensary in the district could be utilized. As the breaking up of the pilgrimages consequent upon an outbreak of cholera was very inimical to the interests of the Hindu priests, the Government should be able to obtain their cordial assistance in carrying out this harmless measure. It was in the epidemic areas of the Punjab and Central Provinces that such a plan of protection was most essential, for those provinces owed their epidemics chiefly to their own pilgrim population visiting the cholera-infected areas and bringing back the disease with them. In the endemic areas themselves the problem was more difficult, but the principle was the same; and he held that no one should be allowed to attend the great fairs at Hardwar, Allahabad, Puri, and elsewhere without first being inoculated against cholera. The sensitization of the cholera vaccine, as worked out in Tokyo, had resulted in an efficient protection combined with an absence of all severe reactions, and this last would be an important point in dealing with the Indian populations. In a brief discussion which followed the paper, Sir Havelock Charles suggested that, before inoculation was made compulsory, the Government should have available a special staff of thoroughly trained men to carry it out. Major W. A. Justice mentioned that in Madras attention had been more or less confined to the provision of protected water supplies in places where the sacred festivals were held, and during the last twenty years this had made a material difference to the incidence of cholera. There was opposition, however, from the pilgrims to the protection and covering-in of the wells on their route. Sir Michael O'Dwyer, speaking as a former governor of the Punjab, said that matters of public health under the reform scheme were in the hands of an Indian minister, and his action in this matter, so important to the well-being of his people, would be one of the tests of the new constitution. Another speaker, Major-General D. Harvey, remarked that a large supply of cholera vaccine was being sent with the troops embarking for China for use if necessary before the cholera season, which began later in the year in Shanghai.

LUIGI ROLANDO.

DR. PIETRO CAPPARONI, in a recent historical sketch,[1] has given an account of an anatomist whose name is familiar to every medical student. Luigi Rolando was born at Turin on June 16th, 1773, where, on the death of his father, he was brought up by his maternal uncle, the learned priest Maffei. From the first he showed a special predilection for anatomy, and became the favourite pupil of Cigna. He also distinguished himself at an early date in clinical medicine and in natural science, particularly zoology. In 1802 he published a dissertation on the structure and function of the lungs in all classes of animals. On November 5th, 1804, he was nominated professor of practical medicine at the University of Sassari in Sardinia. At Florence, where he resided before taking up his appointment in Sardinia, he pursued advanced studies of anatomy with Mascagni and made the acquaintance of Fontana. In 1809 he published an essay on the true structure of the brain in man and animals and the functions of the nervous system, with illustrations which he had drawn and engraved himself. In 1814 he was appointed professor of anatomy at Turin, and during the next fifteen years his scientific output was considerable. He died of carcinoma of the pylorus, in 1831, at the age of 59. During the last years of his life he was physician to Maria Theresa of Austria. Rolando's scientific work was mainly anatomo-physiological and embryological. Though he devoted his attention particularly to the anatomy and physiology of the brain, he published also an important physiological study on the passage of fluids into the solid state, the formation of vegetable and animal tissues, and the vessels and heart, and two zoological works. Rolando is best known for his description of the fissure between the frontal and parietal convolutions which bears his name.

A PRIVATE HOSPITAL SCHEME.

THE directors of the Ladies' National Clubs, Ltd., propose to extend their activities to the provision of a private hospital and nursing home "where the best medical care and efficient nursing can be obtained at fees which gentlefolk of moderate means can afford to pay." A large house has been secured in South Kensington which it is intended to open for the reception of resident and non-resident patients. It is anticipated that each bed in a small ward will cost four guineas a week and private rooms six guineas and upwards; personal laundry, medicines, dressings, and operation room fee are extras. The hospital will be under the supervision of a medical superintendent, who will, when necessary, be able to procure for any member the services of physicians, surgeons, and specialists at modified fees: "Medical list will be sent on application." There will be a sister-in-charge with fully trained nurses under her. The managing director of the club will be the resident organizer. It is hoped that the hospital will be self-supporting, but it is not intended that it shall be run for a profit to the company. It is proposed to provide a guest-house close to the hospital so that members coming to London for medical advice or friends of patients may obtain accommodation. Attached to the preliminary prospectus, of which we have received a copy, is a printed slip giving the names of nine medical practitioners (all of high repute); there is a note that the list is incomplete, and written thereon is the statement, "Not for publication." The scheme is variously described as intending to provide a "private hospital" and "nursing home." Presumably what is really meant is a nursing home, for it is to have some thirty to forty beds. The home appears to be intended for the use of members of the Ladies' National Clubs, who are reported to number some sixteen hundred. The covering letter of the prospectus states: "Members of the clubs are being asked to contribute a fixed sum per annum (10s. 6d. and 21s.) for the upkeep of the hospital, to which they will have the right of admission on the payment of reasonable fees." This statement would indicate that the nursing home is a strictly private concern arranged for the convenience of the subscribers. The wording of the prospectus is, however, a little vague on this point. The policy of the British Medical Association on nursing homes is worth recalling in this connexion—it favours the formation of self-supporting public nursing homes for patients who, being ineligible for the voluntary hospitals, are yet unable to pay the customary professional fees as well as the charges usually made in private nursing homes. The management of such homes should be vested in a committee in which the local profession is adequately represented. Patients should be admitted only on the recommendation of their own doctor. It should be open to a patient to select any registered medical practitioner as his attendant. Modification of professional fees should be made only when there is a satisfactory representation of the particular circumstances of the patient. If this projected nursing home be for the convenience of the members of these proprietary clubs only, the foregoing provisions may not apply to it, since on this assumption they, as subscribers, are solely entitled to admission. But in some of the published accounts of the scheme in the lay press it is stated that

both women and men will be admitted to the home, which would appear to bring this scheme within the policy of the Association as given in these extracts. This is a matter which might well receive the consideration of the promoters of the scheme. On the face of it, the idea of providing for the emergencies that must arise in the large membership of this combination of ladies' clubs would seem to be admirable, but it is not clear that this is the sole field that it is proposed to cover.

SUBCUTANEOUS INJECTION OF B.C.G.

ON January 23rd Drs. Weill-Hallé and Turpin read before the Académie de Médecine a note on "*pre-immunization*" of the infant against tuberculosis by subcutaneous injection of B.C.G. (bacillus Calmette-Guérin). Pre-immunization,[1] it may be remembered, is defined as a vaccination comparable with that produced by vaccinal viruses, but with this difference, that it is bound up with the persistence of the vaccinating organisms in the lymphatic tissues of the immune subject. Calmette administered the vaccine by the mouth in three doses on alternate days within the first ten days after birth. This limitation to ten days was due to Calmette's belief that the intestinal mucosa of newly born animals easily absorbs bacteria, but loses this power in a few weeks. Drs. Weill-Hallé and Turpin found that certain infants from contaminated stocks did not benefit from pre-immunization by ingestion of B.C.G. through the intestinal mucosa. With the approval of Professor Calmette it was decided to try the subcutaneous method, already used for calves. The infants thus treated were carefully selected, were infants of tuberculous parentage, and were from 3 weeks to 9 months old. A single dose of B.C.G. was given, in the earlier cases 1 mg., in the later 1/4 mg., so that the number of bacilli injected was from 10 to 40 million, as compared with 1,200 million given by the buccal method. It appears that there was no general reaction from the injections, and no serious symptom arose. A nodule appeared at the site of injection about the third week, but there was no glandular enlargement. A cold abscess formed by the thirty-fifth or fortieth day. This began to discharge about the eighth week and lasted from two to three months, ultimately healing spontaneously with a punctiform scar. To avoid all fear of the phenomenon of Koch the tuberculin skin reaction was tested several times before the injection was given. After injection the reaction became fairly rapidly positive. One of the ten infants died some time after the injection, apparently from meningitis; but the observers had been unable to obtain particulars. The other nine infants had done well, notwithstanding in some cases exposure to massive infection. Drs. Weill-Hallé and Turpin hoped to be able to report later the minimum efficacious dose that should be injected subcutaneously, and the relative indications for the use of B.C.G. subcutaneously and by ingestion.

THE HOSPITAL PROBLEM IN CANADA.

IN his presidential address before the Manitoba Medical Association last September,[2] Dr. D. A. Stewart made some trenchant comments upon the present state of affairs in the Dominion as regards hospitals and the admission of patients thereto. He urged the need for more hospitals and better hospitals, with broader foundations and better ways of supporting them. Hospitals, he said, were needed for diagnosis and observation, and as retreats for a few weeks' rest for tired-out people, as well as for long periods of rest for chronic cases. Beds were needed also for longer convalescence, which might be both cure and prevention. Hospitals in the past had been quarantine stations for the protection of the community; now they were taking on the functions of community health centres. Just as the factory was the workshop taken out of the home, and the school the teaching of children taken out of the home, so the hospital was the sick-room taken out of the home. The hospital was as logical a place for the sick of the community as the school for its scholars. But there was no problem in social administration more difficult than the founding of hospitals and their conduct on a proper basis, so that they might welcome all, help all, yet hopelessly burden none and pauperize none. The tendency was to throw the whole responsibility upon the public purse, as "a sort of neighbourhood cow that everybody wants to milk and nobody wants to feed." Dr. Stewart recorded his belief that in Canada they had gone far enough in the direction of free treatment, with its tendency to make the individual negligent and forgetful of the fact that the primary responsibility for illness was his own. "Sickness is as often a fault as poverty is. . . . Every doctor knows that, in hard times especially, a differential diagnosis has often to be made between sickness and unemployment, or sickness and imagined sickness." Further, the working out of any scheme of treatment must not overlook the mental and moral factors. "To lose health is bad; but to lose moral stamina is worse. For a man to get out of hospital with legs and lungs healed, and body patched up, but moral backbone flimsy for life, is not a triumph but a tragedy." In Dr. Stewart's judgement a reasonable and workable way of paying the costs of illness might be found "in some general plan of more or less compulsory personal insurance under State auspices. . . . At any rate, the proper time to pay the costs of illness is while well and working, not while sick and spending. Such an arrangement would be a great boon, not only to sick people and the heads of sick families, but to hospitals and doctors as well. Both these unfortunately have to earn their livings from the sick, since the belief still prevails that they that are whole have no need of the physician, but they that are sick."

INFLUENZA.

THE mortality from influenza appears to be waning. In the great towns of England and Wales the deaths diminished last week from 818 to 759, and in London from 215 to 159. Excluding London from the total, the deaths of the last three weeks have numbered 473, 603, and 600. At the time of writing this note the detailed figures of notifications of pneumonia are not available, but the provisional figures suggest a considerable decrease in London and little change in the country as a whole.

LISTER DAY IN CANADA.

THE Lister Memorial Committee of the Canadian Medical Association has arranged that the second Listerian Oration shall be delivered in Toronto on April 5th, the anniversary of his birth. The committee has now proposed that April 5th should be selected every year as a Lister Day in every medical school, hospital, and health centre. One suggestion is that a lecture on Lister should be given in all hospitals, and that every convalescent patient should be invited to attend it. Another suggestion is that the medical profession in every locality should arrange for co-operation with the public health authority, and that Lister Day should be selected for making special appeals in aid of hospitals and of measures seeking to interest the public in the antituberculosis movement, the cancer campaign, and sanitation in general. A final proposal is that medical men should assist the educational authorities in observing the day in some appropriate way in the schools.

RHEUMATIC HEART DISEASE AMONG SCHOOL-CHILDREN IN GLOUCESTERSHIRE.

(Preliminary Note.)

CONSIDERABLE attention has been given recently to the incidence of organic disease of the heart—particularly among the young—in various areas, and to the possibility of mitigating the results on the individual and on the community. The routine medical examination of school children offers exceptional opportunity for a preliminary investigation of the problem, and for an inquiry as to the significance of signs and symptoms pointing to organic disease of the heart due to recognized or unknown attacks of acute rheumatism or to other causes.

In different groups of school children the proportion found affected has varied very widely, the mean as the result of 121,898 examinations of entrants and leavers in Gloucestershire during fifteen years being 7 per cent. affected. Some of the observed differences are probably due to the personal equation of the examiner, but this by no means offers a full explanation, as the following table shows.

Percentage of Children presenting Symptoms consistent with Organic Disease of the Heart.

Year.	Entrants.		Leavers.	
	No. of Examinations.	Proportion Affected.	No. of Examinations.	Proportion Affected.
1915	4,598	2.9	4,193	2.5
1916	4,379	2.9	2,271	3 5
1917	4,763	5.5	718	10.3
1918	5.074	8.4	644	19.6
1919	4,671	10.2	2,827	12.8
1920	5,801	6.6	5,389	9.7
1921	4,550	6.8	4,014	11 6
1922	3,714	4.85	3,783	9.7
1923	3,646	4.55	3,794	9.5
1924	3,999	3.4	3,772	10.1
1925	4,633	2.4	3,579	7.2
1926	5,162	1.7	4, 54	5 65

Percentage in Two Groups of Five Years.

Group.	No. of Examinations.	Proportion Affected.		
		Male.	Female.	Both.
ENTRANTS.				
1916-20	24,688	7.4	6.2	6.8
1921-25	20,542	5.1	3.7	4.4
LEAVERS.				
1916-20	11,849	9.0	10.5	9 8
1921-25	18,942	9.0	10.3	9.7

During the war years comparatively few children were examined as leavers, but in the last seven years there have been about 4,000 entrants and the same number of leavers examined each year. The medical personnel has been the same throughout the past eleven years, with the addition of a fifth examiner at the beginning of 1921.

From the above statement it would appear that with the same personnel and with no conscious variation in standard the proportion of children with signs pointing to organic disease of the heart has varied as follows:

(*a*) Between 1919 and 1926 the proportion of infants (at about 5 years of age) reported to be affected has fallen fairly steadily from 10.2 to 1.7 per cent.

(*b*) The numbers for leavers (at about 12 years of age) between 1919 and 1924 varied from 12.8 per cent. in 1919 to 9.5 per cent. in 1923, and between 1920 and 1924 ranged round 10 per cent. In 1925 the rate fell to 7.2 per cent., and in 1926 to 5.65 per cent.

(*c*) The incidence on leavers is about 50 per cent. heavier than on entrants.

(*d*) Among entrants, boys present these signs more than girls, while at the time of leaving the sex proportions are reversed.

It would therefore seem that for some reason the children born round about 1913 are particularly liable to present signs of heart trouble, and that this liability has steadily diminished among the children born subsequently.

It is proposed to make further investigation, but meanwhile the present observation appears to be of sufficient importance for immediate publication.

J. MIDDLETON MARTIN, M.D., D.P.H.,
County Medical Officer of Health and School Medical Officer.

England and Wales.

THE YORKSHIRE CANCER COUNCIL.

THE Yorkshire Council of the British Empire Cancer Campaign, to which Sir Berkeley Moynihan referred in his Hastings Lecture (SUPPLEMENT, January 29th, p. 29), had its origin in a meeting in Leeds in May, 1925. The Council consists of 130 members, representative of professional, business, political, and social life in the county; Viscount Lascelles is its president, and its vice-president is Sir Berkeley Moynihan, who is also chairman of the Medical and Scientific Committee. An Executive Committee has been formed, which contains members from the districts into which Yorkshire has been divided for the purpose. It has three subcommittees—a finance and general purposes, a medical and scientific, consisting of medical men from all parts of Yorkshire, and another for medical propaganda, containing both medical men and laymen. An appeal was made for £75,000 to establish a cancer research institute in Yorkshire; this amount was soon exceeded and the sum aimed at was raised to £150,000. In the West Riding sixteen districts were formed, each with its committee, honorary secretaries, and treasurers. Local committees have also been formed in the North and East Ridings. Some districts soon collected two or three times the amount at which they had aimed, and the fund will be closed next month. The cost of administration has been kept down to about 2 per cent., despite the fact that considerable sums have been expended on advertising and publicity. Sir Algernon Firth gave £20,000 for the establishment of a research institute in the University of Leeds; pending its completion temporary premises have been secured, and cancer research work is being carried on there by Professor R. D. Passey (the director) and a strong staff, comprising Mr. J. S. Young, *M.C.*, M.B., from the department of pathology, University of Glasgow, and Mr. H. J. Channon, M.Sc., from the biochemical department, University College, London. In addition, two cancer research fellowships have been awarded to Mrs. Bonser, M.D., and Mr. G. A. Collinson, M.Sc., Ph.D., formerly members of the department of pathology of the School of Medicine, Leeds. Work has already been begun; grants have been made also to the departments of physiology and of pathology in the School of Medicine, and to Dr. Cooper for *x*-ray investigations at the General Infirmary at Leeds. A grant has been made to the University of Sheffield towards the research work on cancer in connexion with dietetics, which is being carried on by Professor Mellanby and his assistants. Steps are being taken to establish an experimental farm in direct association with the department of experimental pathology and cancer research. Cases of malignant diseases treated at the General Infirmary at Leeds are being followed up along the lines of Dr. Gretta Wardle, whose previous report on the late results of operation for cancer of the breast (Ministry of Health Reports No. 23) was noticed in our issue of August 14th, 1926 (p. 318). The publication of a pamphlet entitled *Notes on Cancer for Medical Men*, prepared by the Medical and Scientific Committee of the Council, was noted by us a few months ago (October 23rd, 1926, p. 746); it has been sent to every registered medical practitioner in Yorkshire, and a copy can be obtained free by medical men residing elsewhere on application to the offices of the Yorkshire Council, 47, Park

Street, Leeds. This pamphlet contains two short sections directly addressed to the public; the first is on the education of the public on cancer, and the second consists of questions and answers. Copies of these sections can be obtained as leaflets by any medical man desiring to distribute them among his patients. The Propaganda Committee had cancer stalls at the health exhibition in Hull and Rotherham, and it is proposed to have stalls in other towns during cancer exhibition weeks. In its appeal to the public the Council takes care to emphasize the essential importance of an early visit to a doctor for diagnosis in every case in which there is any suspicion of cancer.

THE HUNTERIAN SOCIETY, LONDON.

The connexion between the Hunterian Society and the City of London was illustrated at the annual dinner on February 10th by the presence of the Lord Mayor. Dr. Irwin Moore, in proposing the health of the Lord Mayor and Corporation, referred to the many-sided efficiency of Sir Rowland Blades, and expressed the gratitude of the society for the hospitality accorded to it at the Mansion House. The Lord Mayor, replying, mentioned that he had attended a meeting of the society—a somewhat unusual occupation for the chief magistrate of the City. He went on to refer to other links between the City and the science of healing, and instanced the Barbers Company, originally called the Barber-Surgeons Company at its foundation in 1540, until in 1745 the surgeons severed this association. It possessed a priceless Holbein and some valuable plate, including very fine loving-cups. The Apothecaries Company, with their Hall in Blackfriars, constituted another similar association, and the Corporation, in addition to being responsible for the health of the City, was the sanitary authority for the Port of London. Sir Rowland Blades expressed surprise that more medical practitioners had not become Lord Mayor of London, though they were to be found in both the House of Lords and the House of Commons. The late Sir Thomas Crosby, who had filled the post in 1912, was the only medical man who had ever been Lord Mayor, and this was the more remarkable when it was remembered that Finsbury Square, Finsbury Circus, and Moorfields, which were in the City, had been the headquarters of the medical profession in London before Harley Street became popular. The toast of the Hunterian Society was proposed by the Lord Chief Justice, Lord Hewart, who, in a very humorous speech, cast a side glance at the way in which the medical profession appeared to be conspiring with the Church, the law, and the press. The president of the Hunterian Society, Mr. A. E. Mortimer Woolf, in his reply, stated that the society had been the first to institute discussions with other professions on subjects of common interest; and referred to the recent invitation of the Dean of St. Paul's to medical practitioners to preach in the Cathedral. The toast of "The Guests and Kindred Societies" was proposed by Mr. J. E. H. Roberts, and replies were made by Sir Francis Newbolt, Mr. Hugh Edwards, M.P., and Dr. H. C. Cameron. Sir James Berry proposed the health of the chairman, who, in responding, spoke of the value of the services rendered by the two secretaries.

OSLER PAVILION, HEADINGTON.

The Osler Pavilion, which has been erected on the Manor House estate, Headington, for the treatment of pulmonary tuberculosis, is a branch of the Radcliffe Infirmary, Oxford. The Headington estate, which consists of 140 acres of well wooded land, was purchased by the Radcliffe Infirmary in 1919. The British Red Cross Society contributed £15,000 in order to provide for tuberculous ex-soldiers, their dependants, and for the district in general. The remainder of the money required was raised by a public appeal, and the general funds of the hospital have not been touched. The pavilion, which faces south, contains forty beds distributed in eight single cubicles, eight two-bedded rooms, and two wards containing eight beds each. Recreation rooms for men and women are provided, and the pavilion is connected by a covered corridor with the dining hall and the kitchen block, to the east of which is a building containing an *x*-ray room, a small operating theatre, a pathological laboratory, and a room for light treatment. The old Manor House has been converted into a nurses' home, one wing being allocated to the permanent staff of the pavilion, and the other equipped as a preliminary training school for nurses. The buildings are heated by low-pressure hot-water boilers. Contributions from the county during the last year amounted to £26,000. The Minister of Health, who performed the opening ceremony, said that rapid progress was being made in eradicating tuberculosis by the combination of such different factors as the increasing resistance to the disease among the members of the population, the provision of scientific methods of prevention and treatment, the improvement of sanitary conditions generally, the rise in the social standard of living, and the spread of education among the general public about the prevention of tuberculosis.

MEMORIAL TO THE LATE MR. HAMILTON DRUMMOND.

A meeting of subscribers to the fund for a memorial to the late Mr. Hamilton Drummond, surgeon to the Royal Victoria Infirmary, Newcastle, who was killed in a motor car accident in June, 1925, when returning from a week in camp with his old regiment, the Northumberland Hussars, was held on February 7th, when it was agreed to place a medallion portrait, with a suitable inscription, in the infirmary, and to endow a university scholarship in clinical surgery to be known as "The Hamilton Drummond Memorial Scholarship." Mr. G. Grey Turner said that it would be available during the first two years after graduation, and Sir Thomas Oliver that the proposal would be cordially accepted by the College of Medicine. Subscriptions to the fund have been limited to five guineas, and there has been a gratifying response to the appeal on the part of laymen as well as medical practitioners. The general subscription yielded £866, and a further sum of £268 has been subscribed or promised towards the special Yeomanry account. It is confidently anticipated that £1,200 will eventually be available.

THE WELSH TUBERCULOSIS ASSOCIATION.

Colonel S. Lyle Cummins, professor of tuberculosis in University College, Cardiff, has resigned the additional office of principal medical officer of the Welsh National Memorial Association. He informed the meeting of the Council of the Memorial Association on February 4th that his experience during the last five years had convinced him that the offices should be separated and that the principal medical officership should be a full-time appointment. Mr. David Davies, M.P., who was in the chair, announced that Professor Cummins had consented to accept the position of director of research to the association, to which a salary of £250 a year would attach. The chair of tuberculosis was founded in 1921 by Mr. David Davies and his sisters, by a gift of £12,500. It was announced at the meeting that they had decided to augment this endowment by a further sum of £2,000. Dr. D. A. Powell was appointed principal medical officer; he was one of the first officers to be appointed by the association when it was established in 1911, and with the exception of the war period has continued in its service ever since. He has recently been medical superintendent of the North Wales Sanatorium in the Vale of Clwyd, near Denbigh.

Scotland.

CARNEGIE TRUST FOR UNIVERSITIES OF SCOTLAND.

THE twenty-fifth annual report of the executive committee of the Carnegie Trust for the Universities of Scotland, dealing with the academic year 1925-26, was submitted to a meeting of the Trust at the Universities Bureau of the British Empire on February 9th. Lord Sands, chairman of the trustees, presided. An allocation of funds for the quinquennial distribution, 1925-30, came into operation at the beginning of the year under review. To the universities and extramural institutions a sum of £231,225 had been allocated as follows: St. Andrews, £38,000; Aberdeen, £40,000; Glasgow, £60,000; Edinburgh, £60,500; and extramural institutions, £32,725. The way in which the total was distributed was: for libraries, £24,225; for buildings and permanent equipment, £196,500; and for teaching and general purposes, £10,500. While no altera-

tion had been made in the regulations for the award of fellowships and scholarships, the conditions relative to grants in aid of research had been revised. It had been found desirable to limit the grants in aid of illustration of papers to three-fourths of the actual cost certified by vouchers; in this way it was expected to enlist the author as his own censor. The holders of teaching fellowships are now required to devote not less than half of their time to research. With regard to assistance in the payment of class fees of students, the beneficiaries for the year had numbered 4,711, and had received a total sum of £57,212, as compared with corresponding figures for the previous year of 4,543 recipients and a total of £55,173. At November 30th last the sum of £55,116 had so far been paid for 1926-27 on behalf of 4,643 students. During 1925-26 the sum of £1,510 had been returned by former beneficiaries in repayment of advances for class fees, and forty-eight names had been added to the list of those who had repaid in whole or part. This number of individuals was the highest on record, and the committee felt gratified by this sign of a growing appreciation of the intention and expectation of the founder. The chairman said that the secretary had prepared a history of the work of the Trust, which would be a valuable book of reference to those interested in university work and development in Scotland. He pointed out that whereas the original capital of the Trust was £2,000,000, it had, during the past twenty-five years, expended £2,668,000 on educational and research work in Scotland. Notwithstanding this, the capital had, through prudent investment, augmented to £2,547,000, and the annual income, originally £100,000, was now £125,000. With regard to the payment of students' fees, the Trust required a declaration from the parent or guardian that without assistance by way of payment of part of the class fees the student could not attend the university. The proportion of the total of matriculated students who had the necessary qualifications and whose parents made this declaration could not be less than 70 per cent. The result of such a large number of claims was that the Trust could only pay approximately half the fees for each beneficiary; this, it had been estimated, was equivalent to one-eighth of the total cost of university education. Taking the parents' declaration, therefore, at its face value, in the case of the majority of students the ability of the parent to send son or daughter to the university would seem to turn upon a margin of one-eighth. It was difficult to avoid the conclusion that the declaration was often signed merely as a matter of form. The executive had accordingly arrived at the conclusion that in future new applicants could not be admitted as Carnegie students merely because the application papers and relative declaration were in order, and applications would be considered individually upon their merits in relation to family and other circumstances. It was believed that in this way the assistance rendered to the really necessitous would not be abridged by indiscriminate expenditure. Lord Haldane, in referring to the same matter, said that a special reason why the previous policy should not be continued was the phenomenal increase in the number of students at the universities, which made it more than ever necessary for the Carnegie Trust to husband its resources. It was no exaggeration to say that nowadays every boy or girl who had got the talent and cared for it could proceed to the university notwithstanding the attenuated resources of the parents. This was becoming possible in England also. He thought that as the universities increased more money should be found for them by the State, which was being forced to recognize that universities were national institutions. Sir Donald MacAlister said that the executive committee believed that it would be justified were it to allot the £60,000 annually available for paying students' fees to half the number of beneficiaries and give them twice the present award. Sir Alfred Ewing said that as a rule former beneficiaries who repaid money did not attach any conditions to the repayment, and the money then simply came into the general trust fund. It would be a great advantage if former beneficiaries would give the trustees a freer hand with regard to its expenditure and if a special fund were created from which the trustees would be free to make grants to specially necessitous cases which they were at present obliged to ignore. Mr. H. P. Macmillan said that Mr. Carnegie had fortunately been very generous in the terms of his deed in reposing a discretion in his trustees, and a new departure on such lines was quite within the powers of the deed.

ROYAL MEDICAL SOCIETY OF EDINBURGH.

The annual dinner of the Royal Medical Society was held in the Hall of the Royal College of Physicians of Edinburgh on February 10th. Dr. W. R. Russell, senior president, occupied the chair, and Dr. Robert Hutchison, of the London Hospital, was the principal guest. After the usual toasts, the chairman proposed the toast of "The Guest," and Dr. Hutchison, in reply, proposed "The Royal Medical Society." He mentioned that the Society was unique in many ways—in its old customs, its self-management, and the freedom of its debates. It was now in its 190th session; it had existed side by side with the medical school of the university for nearly two hundred years, and had been an important adjunct to the school. In obtaining medical knowledge the first essential was to acquire knowledge by a solitary process in the wards and lecture rooms. If, however, the knowledge was to be of real use, it must also be digested, and this process of mental digestion was best done in company; in the Royal Medical Society the digestion of the students' knowledge could and did take place.

HOUSING EXHIBITION IN EDINBURGH.

The second annual Housing and Building Exhibition was opened in the Waverley Market, Edinburgh, on February 9th. In connexion with it Dr. W. Robertson, medical officer of health for Edinburgh, delivered a lecture on slums. He defined a slum as a series of houses unfit for human habitation by reason of disrepair, want of light, defective ventilation, and lack of sanitary and other conveniences. The slum stunted growth, dulled the senses, and soured the souls of its inmates. In Edinburgh the very poor houses of long ago had been swept away, leaving the solidly constructed abodes of nobles to endure, and many of them had become the slums of the present day. The dining hall, dormitories, and spacious kitchens of olden days had been subdivided by long dark passages from which eight or ten separate tenements could be entered. Many of those living in slums tried to make the best of them, but too many lapsed into a condition of indifference, carelessness, and improvidence. There were two types of slum population—those who had been reared in the slums and preferred to live and die in them, and those who had gravitated there and were willing, if poverty did not prevent them, to remove to better and higher rented houses. Slum clearance and the provision of alternative accommodation was an economic problem from beginning to end, and, in the long run, local authorities might be faced with the question of bearing the loss rather than tolerate the continued financial drain exacted for public health services.

GIFFORD LECTURES IN GLASGOW.

A fortnight ago we gave an account of the argument of the earlier lectures of the Gifford course Dr. J. S. Haldane of Oxford is giving in the University of Glasgow. In a later lecture he quoted Johannes Müller, who had said that living organisms, which we regarded as unconscious, displayed no exercise of "learning" from experience. Conscious evidence of "learning," from experience. Conscious behaviour had two aspects, which could be distinguished as receptive and voluntary, although they were in fact inseparable. The prediction which controlled conscious behaviour was based on the presence of past experience called memory. Recognition of the distinction between psychological and merely biological phenomena seemed to be essential to clear thinking, just as the distinction between life and mechanism was essential to clear thinking and successful investigation in biology. It had been suggested that when life had attained to a certain stage of organic complexity conscious behaviour automatically appeared; but would it be safe to conclude that, in spite of superficial appearance, something of conscious behaviour must in reality be present behind what appeared to be blind organic behaviour of lower organisms and plants? This was a working hypothesis of which gradual verification

might come as knowledge advanced. Meanwhile the average person, confident in the practical success with which the Newtonian conception had been applied in many directions, continued to apply it to things to which it was not applicable and to suppose that such attempts constituted realism.

VICTORIA INFIRMARY, GLASGOW.

The governors of the Victoria Infirmary, Glasgow, have submitted their annual report for 1926 on the work of the institution, including the dispensaries and the convalescent home at Largs in Ayrshire. The total number of cases admitted during the year was 4,615, of whom 3,178 were surgical and 1,437 medical. The deaths numbered 374—8.1 per cent. of the cases treated to a conclusion; if deaths within forty-eight hours were excluded the mortality was 5.4 per cent. The cases of accident and minor surgical ailment treated without admission numbered 3,167. The throat and nose dispensary at the infirmary dealt with 2,282 patients. There were 20,891 attendances at the electrical department. The operations performed numbered 2,450. Of the total patients admitted the city of Glasgow furnished 3,560, while 1,049 were derived from twenty-one Scottish counties, ranging from Orkney to Wigtown and from the Western Isles to Fife; Lanarkshire sent 565, Renfrewshire 240, and Ayrshire 128. Three patients came from England, two from Ireland, and one from Canada. In the clinical research laboratory 1,935 bacteriological, chemical, and blood examinations were carried out, and 607 microscopic and histological examinations made; special investigations were conducted regarding leptothrix meningitis, myelogenous leukaemia, and the internal secretory glands. At the Bellahouston dispensary there were 42,066 consultations, an increase of 4,405 over the previous year, which is a gratifying demonstration of the utility of the dispensary in the densely peopled area it serves. The sum expended upon the maintenance of the infirmary, dispensaries, and convalescent home amounted to £48,356. The subscribed income for the period was £26,298, which, together with revenue from other sources, fell short of expenditure by £860. The new wing, to be opened shortly by Sir John Gilmour, Secretary for Scotland, which will accommodate 120 extra patients, will involve an additional annual expenditure of about £14,000. The contributions received from patients during the year amounted to £735. The employees' contributions totalled £10,551, a reduction of £455 on the previous year. In view of the industrial conditions of the year a greater decrease might have been expected. The governors highly appreciate the generous contributions of employees during that difficult time. By means of a legacy for the purpose a complete wireless installation has been established, with ear-phones at patients' beds and loud speakers in staff rooms. The building of the auxiliary hospital at Thorntonhall, near Glasgow, the estimated cost of which is £50,000, will begin at an early date.

Ireland.

THE CAMPBELL ORATION, BELFAST.

THE Robert Campbell Memorial Oration was delivered by Sir John Campbell, M.A., F.R.C.S., in the Medical Institute, Belfast, on February 10th. Dr. Nolan, Downpatrick, President of the Ulster Medical Society, occupied the chair, and there was a large audience. The title of the oration was "The renaissance of surgery in Belfast." The speaker dealt with the youth of the late Mr. Robert Campbell, and the effect of his country surroundings and early education on his future career. After referring to his love for the classics, his training in anatomy, his invaluable experience as an assistant in England and his hospital appointments in Belfast, which all gave him the opportunities for the development of his original and logical mind, Sir John Campbell enumerated his operations for perforation in typhoid fever, for hernia in infants at any age, his differentiation of the forms of appendicular trouble and of tuberculous peritonitis, and his investigations of affections of the thyroid gland. The lecturer then went on to discuss the present hospital system, the necessity for change, and the difficulty of providing for patients with only very moderate means who required skilled surgical treatment and nursing. The work done in the past inspired hope for the future; McKeown's removal of steel bodies from the eye by the electro-magnet, and his removal of unripe cataract were examples. X-ray treatment, vaccines, insulin, the causes of monstrosities, and many other subjects still awaited further investigation and gave scope to the energies of youthful enthusiasm. A vote of thanks, moved by Professor Fullerton, P.R.C.S.I., and seconded by Mr. Howard Stevenson, was carried by acclamation, and the chairman presented Sir John Campbell with the gold medal of the oration. Sir Thomas Houston, honorary secretary of the Campbell Memorial Committee, on behalf of the committee, presented to the Ulster Medical Society two replicas of the medal, which was designed by Miss Praeger. The reverse shows the head of the late Robert Campbell, and the obverse the figure of a surgeon bandaging the limb of a child, seated on its mother's lap, with a quotation from Hippocrates, "Where there is the love of man, there is also the love of the art," which had been suggested by the Vice-Chancellor of the University.

PAYMENT OF DISPENSARY DOCTORS' SALARIES WHILE ON SICK LEAVE.

The Ministry of Home Affairs (Northern Ireland) has had under consideration the recommendation made by the Board on November 16th relative to the deductions from the salaries of the dispensary medical officers of Enniskillen and Tempo dispensary districts, and the amounts paid by the Board to Dr. M. E. McBrien for his services as temporary medical officer of the respective districts during the illness of the permanent officers. The Ministry inform the Board that, having regard to the agreement in 1920 made with the dispensary medical officers regarding the payment by them of substitutes employed during illness, the Ministry approved of the deductions in question—namely, a sum of £25 4s. from the salary of Dr. Smyth, medical officer for the Enniskillen dispensary district, and £8 8s. from the salary of Dr. Carraher, medical officer for the Tempo dispensary district. When in 1920 a scale of salaries was made for the Enniskillen Union the medical officers of the area undertook, among other matters, that in the case of illness they would forgo their statutory rights to have substitutes paid by the guardians. This is the agreement referred to in the letter from the Ministry of Home Affairs. Enniskillen is the only union in Ireland in which such an arrangement was made between the guardians and their medical officials.

COUNTY SURGEON AND PRIVATE PATIENTS.

At a special meeting of the County Wexford Health Board a letter was read from the Local Government Department stating that in drawing up regulations under Article 15 of the County Scheme Order for the payment by patients it would be open to the Board to make provision to enable the surgeon to charge fees to private patients. The Board, after consultation with the surgeon, could fix a salary for him, subject to the approval of the Minister, to cover his services towards the patients—paying or otherwise—admitted to the hospital. The Board decided to fix a salary of £800 a year, with existing allowances, to cover the surgeon's services in respect of all patients admitted to the county hospital. The suggestion contained in the letter from the Department of Local Government and Public Health that the Health Board, in consultation with the county surgeon, should arrange for him an inclusive salary to cover the treatment of both private patients and poor persons for whose treatment the Board is statutorily responsible, is contrary to the recommendations forwarded on behalf of the profession to the Local Government Department. It was understood that the Local Government Department had accepted the principal suggestion made on behalf of the profession, that fees to be paid by private patients were a matter of arrangement between these patients and the county hospital doctor, without any interference on the part of the Health

Board. Regulation 7 (1) and (2) bears out this interpretation; its terms are as follows:

(1) The medical officer and surgeon of the hospital may agree with any person admitted to the ward as to the terms upon which such person shall be medically or surgically treated by him and shall be entitled to demand payment of such sums so agreed upon, but he shall out of any such sums received by him from such person pay to the Board of Health any sums that may be due from such person to the Board of Health under Regulation No. 5 which have not been paid to or recovered by the matron of the hospital.

(2) The medical officer and surgeon of the hospital shall, if the person admitted to the ward so requires, permit any duly qualified medical practitioner to have access to such person, and shall so far as possible act in consultation with such medical practitioner. The matron of the hospital shall keep a register, to be known as the Paying Patients' Register, in such form as shall be prescribed or approved by the Minister for Local Government and Public Health, and shall enter therein the particulars required in respect of each person admitted to the wards, and shall furnish an abstract therefrom at the end of each month in such form as may be prescribed or approved by the Minister for Local Government and Public Health to the secretary, to be laid by him before the Board of Health at their ordinary meeting.

SERUM TREATMENT IN DIPHTHERIA AND SCARLET FEVER.

Dr. J. S. Darling, medical officer, Lurgan Union Infirmary, reported to the Lurgan guardians that during 1926 there were treated in the fever hospital 226 cases of fever of all kinds, and that there were six deaths from diphtheria. There had been no deaths among 126 cases of scarlet fever, while during 1925 there had been seven deaths. By the use of the new serum the duration of the treatment of patients had been reduced from six weeks to four and three-eighths weeks. The cost of the serum treatment last year was roughly £100, and he thought the outlay fully justified itself. The Board noted that it was a very creditable record.

Correspondence.

THE MANCHESTER MEDICAL SOCIETY.

SIR,—As the Manchester Medical School is now well over 100 years old, it seems desirable that material relating to its history and the history of medicine generally in the town should be collected carefully lest it should be lost. The Manchester Medical Society has therefore decided to collect and store in its library all material relating to this history, and we are now writing to appeal for such material.

It is difficult to define what is wanted, but we may make a few suggestions—namely, papers, such as minute-books or lists of students of the earlier medical schools, pictures of these schools, diplomas and certificates granted from the schools, reports of prize givings and inaugural addresses, photographs of the medical men of past generations, and letters and diaries written by them. The following episode may be used to illustrate the height of our ambition. In 1840, in the opening address, Thomas Turner, pointing to a small oval table, painted green and set on small wooden wheels, which stood near him, said: "Excuse me making a digression and directing your attention to that table; meanlooking, insignificant, intrinsically of no value as it is, it was the table of John Hunter. This is John Hunter's dissecting table. It would seem almost as if the glory of London anatomy were travelling northward, and that we have arrested it in Manchester. It is more than likely that, on that very table, John Hunter prepared some of those splendid specimens which now enrich the walls of the museum of the Royal College of Surgeons. Let us now, therefore, that we possess a relic of that great man, be stimulated, by the associations it awakens, to pursue the same path that he pursued." Alas! this relic has disappeared.

Doubtless the relatives of former leaders of medicine in Manchester are now scattered all over the world, but this letter may remind them that the memory of those leaders is still treasured.

Communications should be made to Dr. Leech, the Manchester Medical Society, at the University of Manchester.—We are, etc.,

ALFRED A. MUMFORD, M.D.,
President of the Manchester Medical Society.
E. M. BROCKBANK, M.D., F.R.C.P.,
Chairman of the Library Committee.

The University, Manchester, Feb. 17th.

THE MODERN TREATMENT OF HERNIA.

SIR,—The address by Mr. Geoffrey Keynes on "The modern treatment of hernia," published in your issue of January 29th (p. 173), introduces some points of great importance. Two of these I must content myself with emphasizing without further comment—namely, the usefulness of local anaesthesia in dealing with difficult cases and the undoubted value of the inguinal as opposed to the femoral route in dealing with femoral hernia.

To a third point I wish to refer at greater length. He very rightly deals somewhat fully with the use of fascial sutures according to Gallie's technique in operating upon large or recurrent herniae. I am struck, however, by certain points which emerge in dealing especially with inguinal hernia. He says in one place "The whole operation will

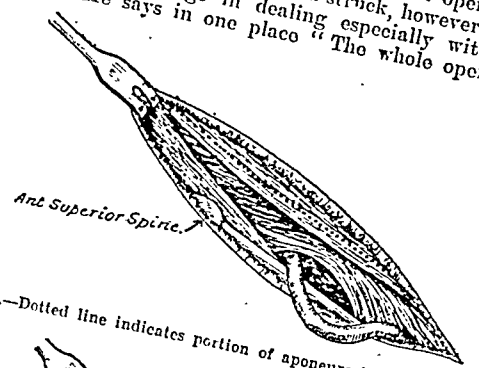

FIG. 1.—Dotted line indicates portion of aponeurosis to be split off.

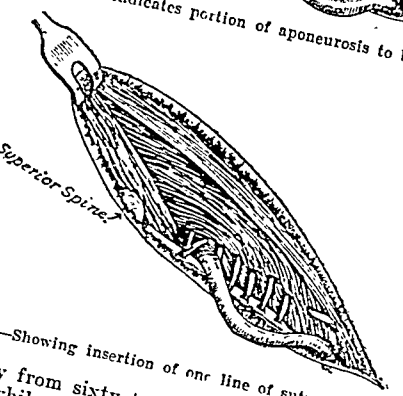

FIG 2.—Showing insertion of one line of suturing.

probably occupy from sixty to seventy-five minutes"; and again, "Meanwhile a second operator . . ." The method I have been using during the last two years does away with the necessity for a second operator and enables the operation to be finished in really very little longer time than the ordinary radical cure. It is applicable in all but exceptionally severe cases where the gap in the parietes is enormous.

The usual incision is made, but it is prolonged outwards and upwards to the level of the anterior superior spine. The external oblique is split in the direction of its fibres from the apex of the external abdominal "ring" if necessary up to the muscle fibres. A strip of aponeurosis about 1/4 in. wide is detached from the upper edge of the split external oblique, and this is cut free at its upper and outer end. The inner end is left attached, thus obviating the necessity for fixing the "tail" of the suture, saving time and also minimizing manipulation of the living suture. The sac having been dealt with, a Cleveland needle is passed through the thoroughly cleaned Poupart's ligament and conjoined tendon beginning at the inner end. The free end of the fascial suture is grasped and pulled through. This process is repeated as often as necessary until the neighbourhood of the internal ring is reached. The "suture" is then made

to encircle the cord and is finished off in the usual way. Neither in this step nor at any other stage must the living graft be drawn tight. The only instruments required are the Cleveland needle and a pair of Spencer-Wells forceps. From first to last the hand should never touch the fascial suture. I make a point of introducing the sutures through conjoined tendon and internal oblique at different levels (Fig. 2), otherwise there is a little tendency to splitting of the muscle and tendinous fibres.

If one strip of aponeurosis is not enough, a second may be used in the same way, to complete or strengthen the first series of sutures. As Mr. Keynes points out, the external oblique is always redundant. There is never any difficulty in getting it together again, and in any case it is well to realize that one is not depending upon the suture of this layer for the efficacy of the cure.—I am, etc.,

Liverpool, Feb. 6th. JOHN T. MORRISON.

ZOOLOGICAL NOMENCLATURE IN MEDICAL LITERATURE.

SIR,—I should like to reinforce the appeal of Professor R. T. Leiper, F.R.S., and the hope expressed by you in the BRITISH MEDICAL JOURNAL dated December 11th, 1926 (p. 1129), *that something may be done to obviate the grave* inconvenience caused by the tiresome pedantry of the archaeo-parasitologists.

May I quote one illustration? As the result of the strict application of the "law of priority" adopted by the International Congress of Zoologists the identity of the commonest anopheline mosquito of India and of certain other parts of the East, so long and so familiarly known as *Anopheles rossii*, is now hidden under the name of *Anopheles subpictus*.

Here surely was an instance in which the taxonomists might well have exercised the discretion with which they have invested themselves. The anopheline mosquitos derive much of their importance from the fact that they "carry" malaria. It would therefore seem a not unreasonable proposition that the commonest anopheline mosquito in the country where Sir Ronald Ross made his epoch-making discovery—a species, moreover, which he used in some of his original experiments—should have been allowed to retain the name by which it has been known for a quarter of a century. To malariologists in the East the name "*rossii*" is as familiar as a household word.

I cannot help thinking how much kinder Nature is than man, in spite of the "struggle for existence." She at least changes her species by a slow and imperceptible process of evolution, but man, as represented by the taxonomists, appears to take a delight (from a stern sense of duty) in "sinking" their names without scruple and without remorse.—I am, etc.,

Lahore, Jan. 5th. C. A. GILL, Lieut.-Colonel I.M.S.

ANTIGENS FOR THERAPEUTIC IMMUNIZATION.

SIR,—Although one is accustomed from time to time to see grave doubts expressed in medical journals concerning the therapeutic value of serums and vaccines, it is a new experience to read (BRITISH MEDICAL JOURNAL, July 31st, 1926, p. 177), on the authority of men like Sir Thomas Horder and Dr. N. S. Ferry, that the resultant products in the preparation of antigens for immunizing properties exist in a crude state, and that they contain products of no value in the process of immunization, and *which are not seldom extremely injurious to the patient*, as well as to the antigen itself. Some sixteen years ago, in my little book on tropical conditions, the following words were used with reference to immunization, and after a fairly extensive experience, gained partly during the war as physician in charge of fever and dysentery wards, I see no tangible reason for altering my opinions; indeed, Horder and Ferry's statements could only serve to strengthen them.

"Such may be an attempt to follow Nature's system of immunization, but what Nature has taken centuries to accomplish by the extremely slow adaptation of certain organisms to the environment, artificial immunization attempts to accomplish abruptly by profoundly modifying the vital fluids of the body. To assert that the very abruptness of such practices may upset the natural standard of life would be as rash as to deny it." . . . "Nor can we ignore entirely any possible ulterior results that may supervene after injection of some millions of dead micro-organisms into the tissues of a healthy individual."

In view of the widespread use of specific products in the prophylaxis and cure of disease—due possibly in no small measure to commercial exploitation—to the very definite limits to their usefulness, certainly in infective processes, and to the positive danger to the patient from their use, the time would appear to be overdue when an authoritative pronouncement should be made on the results of such practices.

Although there appears to be a consensus of opinion in *favour of vaccines as prophylactics against the typhoid* group of fevers, their use has been by no means invariably crowned with success nor entirely free from unpleasant results. The success obtained in France during the war was, of course, undeniable, especially if considered apart from other factors; but I have seen many severe inoculated cases from Gallipoli and other places where the sanitary conditions were not altogether ideal, and during a recent epidemic in a German town, among 1,500 inoculated cases over 70 developed typhoid of average severity. But some recent personal experiences have afforded much cause for reflection, without, however, offering any satisfactory solution.

1. Miss A. was inoculated in New York before departure, again in the Atlantic, and for the third time in the Mediterranean. Very shortly after arrival in Egypt a very serious form of enteric (with one relapse) developed. At the outset the symptoms were very obscure, and the abdominal symptoms were so severe and persistent that intestinal obstruction was suspected.

2. In the case of Miss B., shortly after the third inoculation (American practice) jaundice developed, which was very persistent; it was treated by emetine by the doctor in charge. Finally enteric was diagnosed, and after a prolonged convalescence (with one relapse) the patient recovered. Books written in the last generation allude to jaundice as a rare complication of typhoid fever; certainly during the war it was not an infrequent complication, and since then there would appear to be a number of sporadic cases which might repay closer investigation.

3. Miss C., also an American, had three inoculations six weeks previous to illness, which, clinically (fever, abundant rash, enlarged spleen), appeared to belong to the typhoid group, and was diagnosed by two Italian doctors as paratyphoid, but the abdominal symptoms and signs were too pronounced to allow me to agree. The fever subsided and other symptoms disappeared at the end of three weeks, but unfortunately no bacterial tests were possible.

4. The case of Mr. D., aged 42, was of an entirely different nature. The patient contracted posterior urethritis with complications. Had two separate attacks and underwent, in London, vigorous vaccine treatment, apparently with relief. A few years afterwards grave myocardial disease developed, and, after much suffering, proved fatal.

It has been seriously asserted in some quarters, on evidence not available, that this form of therapy does give rise to myocardial disease, and in this connexion it may be of interest to state that Luys asserts that gonococcal myocarditis is never found alone, that it is always associated with endocarditis, or as a sequela of the latter or pericarditis, conditions non-existent in this instance. If, then, as alleged, vaccine therapy is of no real value except in a few definite conditions, that it may possibly be "extremely injurious to the patient," it may be permissible to ask why is its employment so general and so much sought after by the public?

We may well smile at the crude notions of the ancient Egyptians concerning the medical art, with their invocations and magical formulae, but at least their "words of power" were invoked over products mostly innocuous.—I am, etc.,

Cairo, Jan. 19th. T. GERALD GARRY, M.D.

THE MENTAL DEFICIENCY BILL OF 1926.

SIR,—I agree with Sir Bryan Donkin that the definition of "mental defectiveness" in the above bill is "too vague."

The letters from Dr. Tredgold and Sir Bryan Donkin prove this to be the case, for the former limits the period of mental development to the first eighteen years of life, whilst the latter appears to limit it to the first twenty-five years of life, and it is quite possible that some other authority would place the limit at another age.

In order to prevent this uncertainty the definition of mental defectiveness should contain some precise time limit to the expression "mental development" as used in the

bill. By the English and American law persons come to majority at the age of 21 years, until which time they are under guardianship. Until they have attained their majority they can possess, but they cannot manage or control, property, for they are not supposed to have sufficient discretion or ability for this purpose. I think it would be generally admitted that mental development is complete at the age of 21 so far as "managing himself and his affairs" are concerned. If this age limit were introduced into the definition it would prevent any ambiguity and conform with existing law. I suggest a definition on the following lines:

"Mental defectiveness means an imperfect condition of mind due to its arrested development either before or during the first twenty-one years of life; this condition may be induced by injury, disease, or other cause."

I am strongly in favour of retaining the fourth class of mental deficiency under the title of moral defective. The Mental Deficiency Act, 1913, appears to me to legislate for two distinct types of mental defect: (1) a defect of the intellectual faculty; (2) a defect of the moral faculty.

The first three classes defined under the Act—idiot, imbecile, and feeble-minded—are different degrees of the same defect, namely, an intellectual defect. Many feeble-minded persons, owing to their defect, commit anti-social acts and are quite properly certified as feeble-minded persons. But there is a class of person who is morally defective without any intellectual defect. Such a patient I do not consider certifiable as a feeble-minded person. It is true that they require care, supervision, and control like the feeble-minded, but the feeble-minded person is, by definition, related to the imbecile and idiot—it is only a question of degree. The moral defective who has no intellectual defect cannot be said to be related to the imbecile, and he should not be certified as, or treated with, the feeble-minded.—I am, etc.,

Leicester, Feb. 7th. ALLAN WARNER,
Medical Officer to the Mental Deficiency Committee

HISTORY OF DIPHTHERIA.

SIR,—In Sir Humphry Rolleston's address (JOURNAL, January 15th) the late J. G. Adami is quoted as suggesting the transformation of some previously harmless diphtheroid bacillus to account for the appearance of diphtheria at the beginning of the last century—"a disease so sharply cut that it could hardly have been overlooked by all physicians until Bretonneau of Tours gave his classical description in 1821." Further references to the disease are given by correspondents, the earliest of which appears to be that by Gooch in 1740. I can record a much earlier reference than this to what is undoubtedly an epidemic of diphtheria, in a little book in my possession entitled "Miscellaneous Observations in the Practise of Physick, Anatomy, and Surgery . . . communicated in several Letters to Eminent Physicians and Learned Members of the Royal Society, viz., Sir Hans Sloane, Dr. Mead, Dr. Halley, Dr. Douglass, Mr. Petiver, etc., by Patrick Blair, M.D., F.R.S., London, 1718." In the section of this book headed "A second letter to Dr. Richard Mead concerning some Epidemical Diseases in Scotland," the following occurs:

"The Tussis convulsiva or Chink-cough, is also some Years Epidemical, and becomes universal among Children; as is a certain Distemper with us, called the Croops, with the Variety, that whereas the Chink-cough encreases gradually, is of a long continuance, seizes in Paroxysms, and the Patient is well in the interval. This Convulsion of the Larinx, as it begins so it continues, so violently, that unless the Child be relieved in a few Hours, 'tis carried off within twenty-four, or at most forty-eight Hours. When they are seized they have a terrible snorting at the Nose and Squeeking in the Throat, without the least Minute of free Breathing, and that all of a sudden, when perhaps the Child was but a little time before healthful and well."

Here we have a description of an epidemic disease in children whose main symptoms, in fatal cases, were extreme laryngeal obstruction and stridor, and this can only have been diphtheria. As far back as 1718, therefore, the Klebs-Loeffler bacillus was as virulent as it is now. That it was so, too, much earlier than this, I could bring a considerable body of evidence to establish. In the books in my possession, published between the years 1570 and 1700, the disease "squinancy" (quinsy) is described, apparently common and much dreaded for its frequently fatal issue, and undoubtedly diphtheria would be included as a "squinancy." In support of this opinion I will quote "The General Practise of Physicke . . . compiled and written by the . . . learned Doctour Wirzung in the germane tongue and now translated into English . . . by Jacob Mosan, germane, Doctor in the same facultie. London, 1617." In the second part of this treatise is a section entitled "Of the squinancie or swelling of the throate." This commences with a very involved description of varities of the disease, from which it appears that one of these varieties "ariseth about the throte, in the mouth, and about the throte boil, and very quickly stoppeth the breath." Further on he says:

"*First* . . . So doe the learned devide the same into foure kinds: *Secondly*, if about the throate there be no swelling seene on the outside, notwithstanding above all this, that the breath is so short that one would think the patient would be strangled." In the next paragraph he says: "But after what manner soever it commeth, it is alwaies a perillous sickness and especially the second kind, for that it is very quick and speedy, so that oftentimes it dispatcheth one in two or three daies; and commonly is more dangerous for children than for aged folk: therefore doe the Latinists call this kind of squinancy Strangulatorem, which is Strangler. . . ."

Some of these cases of squinancy occurring more commonly in children, with little or no swelling of the neck and causing death by laryngeal obstruction, could hardly be other than diphtheria. I should like to quote the learned Dr. Wirzung's treatment of the disease, but space forbids. There is no mention of any surgical interference.

Diphtheria, therefore, seems to have occurred in Europe at least 310 years ago, and there is no evidence of a sudden mutation of a diphtheroid bacillus into the true Klebs-Loeffler bacillus about 100 years ago.—I am, etc.,

Tunbridge Wells, Feb. 7th. C. F. SELOUS.

THE PREVENTION OF GOITRE.

SIR,—The conclusive and successful experimental work of Colonel R. McCarrison on goitre prevention ("An experiment in goitre prevention," BRITISH MEDICAL JOURNAL, January 15th, 1927, p. 94) at the Lawrence Royal Military School, Sanawar, India, confirms his earlier evidence in 1913 and 1914 that endemic goitre is due to bacteriological impurities in the water supply, and that it can be eradicated by the provision of a pure potable water. Surely this far-reaching conclusion is so important that it merits the collaboration of the Medical Research Council and the Swiss committee for the investigation of goitre?

As pathologist to the Royal Sussex County Hospital, and later as a school medical officer to the West Sussex County Council, I collected data and reported them on the close association that was obvious in 1911 and 1912 between my analyses of the shallow well waters of the West Sussex villages (which were usually impure by bacteriological and chemical standards) and my school records of the prevalence of enlargement of the thyroid (amounting in many cases to true goitre) in the children and young people in these rural districts. Since then I have observed similar relationship between impure water supplies and goitrous enlargement of the thyroid in Plymouth and districts adjacent.

It appears that on such evidence goitre could be eliminated from the United Kingdom by the provision of pure water supplies in districts where it is not already eradicated, and that medical officers of health and school medical officers could determine this important hygienic question in their areas. I was surprised to learn in Switzerland last summer on good authority that goitre research workers were not known to have taken action on McCarrison's work, as drinking water supplies (at any rate in Swiss rural districts where goitre in endemic) are obviously open to gross pollution, though clear, cold, and sparkling.—I am etc.,

Plymouth, Jan. 22nd. F. G. BUSHNELL, M.D.

THE CAPTAIN OF THE MEN OF DEATH.

SIR,—Sir Berkeley Moynihan, in his Hastings Lecture, acclaimed cancer as the "Captain of the men of death." This is to do an injustice to the real captain—heart disease.

Dr. Moore, medical officer of health for Huddersfield,

has kindly extracted for me, from the Registrar-General's Statistical Review for 1925, the number of deaths from cancer and heart disease during that year. The deaths in England and Wales in 1925 were: from cancer 51,939; from heart disease, including pericarditis, acute endocarditis and myocarditis, and angina pectoris, 64,059. If pericarditis, endocarditis, myocarditis, and angina pectoris are not included, the deaths from heart disease total 59,894. The return for 1924 shows a like preponderance of heart disease. Unfortunately the need for a campaign against heart disease has not stirred public imagination, although the British Medical Association, by its investigation into the causes of rheumatism, is giving the nation a much needed lead.—I am, etc.,

Llandudno, Feb. 3rd. NORMAN PORRITT.

MEDICAL GOVERNORS.

SIR,—To the roll of medical governors noted in the JOURNAL of February 12th (p. 295) may fitly be added the name of Sir Samuel Rowe, K.C.M.G. Qualifying in 1856, he was in 1862 appointed on the Army Medical Staff and sent to Lagos, where his administrative gifts were utilized both in the civil service and in dealing with the native tribes. In 1864-65 he came home on leave, and utilized the opportunity to take his degree at the University of Aberdeen. He then returned to West Africa, and for a number of years held various appointments, civil as well as medical. In the Ashanti war of 1873 he took a prominent part in withstanding the early invasion of the British territories, and during the war he acted on the staff of the expeditionary force under Sir John Glover. These services were recognized by the award of the C.M.G., followed later by promotion to K.C.M.G. From 1876 onwards he was governor successively of Gambia, Sierra Leone, West African Settlements, and Gold Coast and Lagos. He retired from the army with the rank of brigade surgeon, and in 1886 Aberdeen made him an honorary LL.D. He died at Madeira on his way home in 1888.—I am, etc.,

London, W., Feb. 14th. C. O. HAWTHORNE.

Obituary.

DOUGLAS DOUGLAS-CRAWFORD, M.B., C.M.EDIN., F.R.C.S.ENG.

Honorary Surgeon to the Royal Southern Hospital, Liverpool.

WE regret to record the death of Mr. Douglas Douglas-Crawford of Liverpool, on February 7th, at the age of 60. While apparently in his usual health and at work he collapsed suddenly, and passed away very quickly from cerebral haemorrhage.

A native of Liverpool, he spent his undergraduate life in Edinburgh, where he graduated M.B., C.M. in 1887, after which he became a demonstrator for the late Professor Melville Paterson at Dundee. He studied later in Berlin and at University College Hospital, and obtained the F.R.C.S. in 1894, in which year also he joined the staff of the University of Liverpool as assistant demonstrator of anatomy with Professor Paterson. Until the day of his death the importance of anatomy in surgery was an outstanding feature of his life's work. By every means in his power he sought to promote the study of anatomy as applied to surgery, both general and dental, and in 1912 was a vice-president of the Section of Anatomy at the Liverpool Annual Meeting. In 1903 he was appointed lecturer in surgical and applied anatomy; in 1907 lecturer in clinical surgery; in 1912 lecturer in surgery for dental students; and during the year 1925-26 he was chairman of the Faculty of Medicine. Throughout the whole period of his association with the University he took a remarkable personal interest in medical and dental students; his secret kindnesses and benefactions were very many, and his reticence was a fine element of his character. In 1895 he was appointed assistant surgeon to the Stanley Hospital, and full surgeon in 1898; twelve years later he became attached to the Royal Southern Hospital, where the bulk of his hospital surgery was carried out during the past seventeen years. At the time of his death he was senior honorary surgeon to this institution, and also held the posts of consulting surgeon to the Liverpool Dental Hospital, the Hoylake and West Kirby Cottage Hospital, and the Druids Cross Hospital. These posts were no sinecures, and most of the time an ordinary doctor would have deservedly counted as brief spells of recreation or leisure he spent in devoted attention to this work. During the war he served with the 1st Western General Hospital (Territorial) in Liverpool and overseas.

He was unstinted in giving, whether of work, advice, or more material means. He was an ardent supporter of, and acted as surgeon to, the Caledonian Association, and in this manner also found many opportunities of unselfish service. Among his colleagues he was universally popular, and in the Liverpool Medical Institution he held at different times the posts of secretary for pathological meetings and vice-president. By practitioners in a wide area and by private patients he was revered and loved for patent honesty and a great fund of human charity. A man of action rather than of words, he yet contributed from time to time, principally to the *Liverpool Medico-Chirurgical Journal*, articles of characteristic vigour; in debate or discussion he was often incisive, but always kindly and generous.

The memorial service held in Liverpool Cathedral was a fitting testimonial to the man and his work. It was attended by a very large congregation of sorrowing friends who, while mourning the sudden close of a valued life, were yet proud to recall its happiness and many merits. To his devoted widow we extend sincere sympathy.

ARTHUR HIRST WATKINS, M.D., C.M.,

Senator, Union of South Africa.

THE death occurred suddenly on the evening of December 24th, 1926, of Senator the Hon. A. H. Watkins, at the age of 76. He had been seized with cerebral apoplexy the previous evening. He was born at Brentford, Middlesex, and received his early education at Clevedon and his medical education at Glasgow and Edinburgh, graduating at Edinburgh in 1875, and obtaining the doctorate in 1883. He settled in South Africa in 1875, practising first at Alice in the Cape Colony, later at Boshof in the Orange Free State, and lastly at Kimberley. Here he built up a very large practice until in 1910 he went into politics. In that year he was elected a member of the Legislative Assembly, having contested the Barkly West seat as a Unionist; the Unionist party, it may be remembered, was the official Opposition to the South African party led by General Botha in the first Parliament of the united provinces of South Africa. He continued to represent this constituency until 1920, when he was defeated at the polls, but in the following year he was elected to the Senate. His election to the Upper House was undoubtedly the result of the respect which members of all parties had for him.

The medical profession in South Africa owes him much. He served the Griqualand West Branch of the British Medical Association well, and was many times its president. He was for a time a member of the board of management of the Kimberley Hospital. In 1910 he was appointed a nominee member of the Cape Colonial Medical Council, and was reappointed at each succeeding nomination until in 1921 he was elected president—an office which he continued to hold until his death. He did much, too, for education and devoted much of his time to its advancement; he was one of the founders of the Kimberley Public Schools, and was for many years chairman of the Kimberley School Board. He found leisure to write a novel on South African life, *From Farm to Forum*; though its literary merit was not great, it was yet of considerable value as a portrayal of conditions in that country during an interesting historical period.

He married in 1876 a daughter of the late Sir Thomas Fuller, and sister of Dr. E. B. Fuller; she died in 1903; he married again in 1910, and his second wife, who was the widow of Mr. James Brown, dental surgeon, of Kimberley, survives him. He had no children. He was buried at Maitland Cemetery in the Cape Peninsula. The funeral was attended by many senators and members of the Legislative Assembly, by the members of the (Cape) Colonial Medical Council, and numerous friends.

W. C. BEEVOR, C.B., C.M.G.,
Colonel, R.A.M.C., T.F.

COLONEL WALTER CALVERLEY BEEVOR, C.B., C.M.G., R.A.M.C. (ret.), died suddenly of heart failure in London on February 6th, aged 68. He was the son of Mr. John Beevor, M.P., of Newark-on-Trent, and was educated at Edinburgh, where he graduated M.B. in 1880; he took the M.R.C.S. in the same year. After filling the posts of house-surgeon at the Royal Portsmouth Hospital, the Newark-on-Trent Hospital, and the Midland Counties Eye Infirmary, he entered the Army Medical Service as surgeon on August 2nd, 1884, and was appointed medical officer of the Scots Guards in November, 1885. He became surgeon major, on special promotion for Ashanti, on March 25th, 1896, was transferred to the Grenadier Guards on June 26th, 1897, to the Coldstreams on September 14th, 1898, and again to the Scots Guards two months later. He reverted to the R.A.M.C. as major on May 25th, 1904, and retired on August 20th, 1913. colonel in August, 1904, and became lieutenant-colonel in 1883 with second class honours in natural science. After his retirement he joined the R.A.M.C., T.F., North Midland Division, as lieutenant-colonel and D.A.D.M.S., and was promoted to colonel, R.A.M.C., T.F.; he became D.M.S. on December 3rd, 1914, and served as such throughout the great war.

He had a long record of war service: Sudan expedition, 1885, at Suakin, Egyptian medal with clasp and Khedive's bronze star; Ashanti expedition, 1895-96, mentioned in dispatches, specially promoted to surgeon major, star; north-west frontier of India, 1897, Tirah, mentioned in dispatches, *London Gazette*, April 5th, 1898, frontier medal with two clasps; South African war, 1899-1902, advance on Kimberley, actions at Belmont, Enslin, Modder River, and Magersfontein; operations in Orange Free State, actions at Poplar Grove, Dreifontein, Vet River, and Zand River; operations in Transvaal, actions at Pretoria, Johannesburg, Diamond Hill, and Belfast; mentioned in dispatches, *London Gazette* of September 10th, 1901, Queen's medal with six clasps, King's medal with two clasps, and C.M.G.; war of 1914-18, mentioned in dispatches, *London Gazette*, January 1st, 1916, and May 29th, 1917, C.B. He was the first to take and use an *x*-ray apparatus on active service, which he did in the Tirah expedition of 1897-98. He served on the staff of the Duke of Connaught at Lord Curzon's Delhi Durbar in 1902, and on the staff of Lord Northcote, Governor of Bombay, in 1903.

In 1890 he married the eldest daughter of Mr. Charles Taylor, J.P., of Horton Manor, Slough, and had one son and one daughter.

We regret to record the sudden death, at Weybridge, on February 2nd, of Dr. FREDERIC OSMUND STEDMAN, whose valuable work for the profession in Hong-Kong is well known to many of our readers. He was born in Devonshire in 1863, and in entering the medical profession followed the example of his father and grandfather, who both practised at Bookham in Surrey. From Epsom College he went with a scholarship to Charing Cross Hospital, and obtained the L.S.A. diploma in 1884 and the M.R.C.S. in the following year, graduating later as M.B., B.S.Lond., and proceeding to the M.D. degree in 1888. Before he went to China and settled in practice in Hong-Kong he had held the posts of house-physician, house-surgeon, and surgical registrar at Charing Cross Hospital, and of house-physician to the National Hospital, Queen Square, London. Dr. Stedman was keenly interested in the British Medical Association. For many years he took an active part in the work of the Hong-Kong and China Branch Council, holding office as vice-president in 1897 and 1903, and president in 1901. He represented the Branch upon the Central Council of the Association from 1904 to 1906, and again in 1920-21, and during 1921 he served also on the Dominions Committee. He was a member of the Representative Body at the time of the Annual Meeting at Cambridge in 1920, on his retirement after twenty-five years' practice in Hong-Kong. Since then he had lived at Weybridge, and devoted much of his leisure to the business of the local cottage hospital, of which he was honorary treasurer.

The death of Dr. CHARLES JOSEPH HARRISON of Chelsea occurred on February 7th, after a short illness due to influenza. Dr. Harrison received his medical education at University College Hospital; he graduated M.B., B.S.Lond. in 1892, obtained the diplomas M.R.C.S., L.R.C.P. in 1893, and proceeded M.D. in 1894. After holding the post of house-surgeon at the Victoria Hospital for Children he settled in Chelsea, where he practised for thirty-three years; he was honorary physician to the Chelsea District Nursing Association, and to the Chelsea, Belgrave, and Brompton Dispensary. During the war he acted as surgeon to the Fulham Military Hospital.

Dr. FRANCIS SORELL ARNOLD, who died at Painswick, Gloucestershire, on February 5th, in his sixty-seventh year, was a son of Thomas Arnold, M.A., a nephew of Matthew Arnold, and a grandson of Thomas Arnold, D.D., headmaster of Rugby. He received his early education at Clifton College and went up to Christ Church, Oxford, with a junior studentship in 1879; he graduated B.A. in 1883 with second class honours in natural science. After studying medicine at St. Bartholomew's Hospital he obtained the M.R.C.S. and L.S.A. diplomas, and graduated M.B., B.Ch.Oxon. in 1887. He then served as house-surgeon at the Radcliffe Infirmary, Oxford, and afterwards settled in general practice at Bovington and Berkhamsted. In later life he moved to Painswick, where he became medical officer to the Stroud Union. Dr. Arnold district medical officer under the Gyde Orphanage, and inherited some of the scholarship of his father's family, and had a sound literary knowledge of most of the modern European languages. He translated into English Bing's *Compendium of Regional Diagnosis in Affections of the Brain and Spinal Cord*, Guelpa's *Auto-intoxication and Disintoxication*, and Schlesinger's *Local Anaesthesia*. In 1899 he published a small work on the modern therapeutics of pulmonary phthisis, a subject to which he had given much thought during the time he acted as medical superintendent of the Hailey Open-Air Sanatorium. He was for many years a member of the West Herts Division of the British Medical Association, and latterly of the Gloucestershire Branch.

Dr. JOHN WILLIAM STEVEN died at his home in Edinburgh on February 10th; he had had a long illness following an attack of pneumonia, and had been completely laid aside from professional work for some months. He graduated at Edinburgh University in 1889 and took the Fellowship of the Royal College of Surgeons of Edinburgh ten years later. Dr. Steven conducted a very large practice, chiefly under the National Health Insurance Act, and he was greatly beloved by his patients. He was very fond of sport, especially of angling, and when he could seize an opportunity to escape would betake himself for several hours to the banks of some quiet border stream. He was unmarried.

Dr. FRANCES ELIZABETH HOGGAN, whose maiden name was Morgan, died at Brighton on February 5th. She was born in 1843; she received her medical education at Zürich, Prague, and Vienna, and graduated M.D. Zürich in 1870, six years before the passing of the Medical Act (1876) which opened the medical profession in England to women. She obtained the diplomas L.R.C.P.I. and L.M. in 1877, and the M.R.C.P.I. in 1880. She was one of the first women to practise in England, and, with Dr. Garrett Anderson, was a physician on the staff of St. Mary's Dispensary in Crawford Street, which subsequently became the New Hospital for Women. Owing to the ill health of her husband she lived in the South of France until his death in 1900, when she returned to London. Soon afterwards she visited America, where she became interested in the colour question, and published articles on this subject. When over 60 years of age she accompanied an exploring expedition to native villages of South Africa. For the last five years she had resided in Brighton. Her health failed during the last three months, but up to that time she had been very active in body and mind and took a deep interest in professional matters.

The Services.

ARMY MEDICAL SERVICES.

Scholarships for Sons of Medical Officers.

SIX years ago the Aldershot R.A.M.C. Fund Committee endowed four scholarships, one to be competed for annually at Cheltenham College. The foundation is for the benefit of the sons of all officers of the R.A.M.C. The first two scholars who entered Cheltenham under this scheme have just left, having taken fifth and sixth places respectively on the Woolwich and Sandhurst lists of December last. Both are awarded prize cadetships into those institutions on account of their high positions on the lists. It is not generally known that the sons of all medical officers, Regular, Special Reserve, Territorial, and Temporary, who died of wounds or disease during the great war are primarily eligible to compete for these scholarships, and that in default of candidates under this category, the sons of all living medical officers serving or retired come within the scope of this foundation. In the event of any boy falling short of scholarship standard money grants are sanctioned in suitable cases, and several boys are receiving these benefits at the college now. The value of the scholarships is approximately £50 per annum, tenable for four to five years, a purely classical or modern education being given at the desire of the parents or guardians. Further particulars can, we understand, be obtained on application to Major-General Sir S. G. Guise-Moores, K.C.B., Osborne House, East Cowes, Isle of Wight.

HONORARY PHYSICIAN TO THE KING.

COLONEL JOHN GRAHAM MARTIN, T.D., A.D.M.S., 55th (West Lancashire) Division, T.A., has been appointed Honorary Physician to the King in succession to Colonel G. H. Edington, T.D., retired.

FOREIGN DECORATIONS.

THE KING has granted unrestricted permission to the following officers of the Canadian Army Medical Corps to wear the medals indicated awarded by the French Government in respect of services rendered during the war 1914-19:

Medaille d'Honneur des Epidemics.—En Vermeil: Major G. Archambault, Captains L. B. Blagdon, R. Dumont, A. Larose, and G. Lefebvre. En Argent: Captains A. J. Lefleur and J. G. du Val.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE.

ON the nomination of the Council of the Senate the following have been appointed electors to the professorships indicated: Anatomy, Sir Humphry Rolleston, Bt.; Medicine (Downing), Professor A. V. Hill, F.R.S.; Pathology, Sir Charles Sherrington, G.B.E., F.R.S.; Biochemistry (Sir William Dunn's), Sir William J. Pope, F.R.S.; Animal Pathology, Sir Walter M. Fletcher, F.R.S.

At a congregation held on February 12th the degree of B.Chir. was conferred on W. L. Roberts (admitted by proxy).

UNIVERSITY OF LONDON.

THE following have been recognized as teachers of the University in the subjects at the institutions indicated:

University College.—Mr. H. A. Harris (anatomy).
Guy's Hospital.—Dr. J. M. H. Campbell (medicine).
St George's Hospital.—Dr. H. Gainsborough and Dr. T. S. Nelson (medicine), Mr. G. R. E. Colquhoun (surgery).
London Hospital.—Mr. W. Morris and Mr. G. W. Carte (oto-rhino-laryngology), Mr. V. J. F. Lack (midwifery and diseases of women), Dr. A. G. Maitland-Jones (diseases of children), Dr. W. J. O'Donovan (dermatology and venereal diseases), Mr. A. C. Perry and Mr. H. W. B. Carns (surgery).
London School of Medicine for Women.—Miss Joan M. Ross (bacteriology and pathology).
University College Hospital.—Dr. C. White (midwifery and diseases of women), Dr. R. W. A. Salmond (radiology).
Maudsley Hospital.—Dr. W. Moodie (psychiatry), Dr. W. N. East (mental diseases of psychiatry).

The following is the constitution of the Boards of Examiners for the second examination for medical degrees in 1927, the chairmen of the respective boards being indicated by an asterisk:

Anatomy.—G. E. Smith (University College), *E. Barclay-Smith (King's College), W. E. Le Gros Clark (St. Bartholomew's Hospital Medical College), F. G. Parsons (St. Thomas's Hospital Medical School), T. B. Johnston (Guy's Hospital Medical School), W. Wright (London Hospital Medical College), Mrs. Lucas Keene (London School of Medicine for Women), J. E. S. Frazer (St. Mary's Hospital Medical School), together with the external examiners.
Pharmacology.—E. B. Verney (University College), O. Inchley (King's College), P. Hamill (S[illegible]), N. Match (Guy's Hospital [illegible] Hospital Medical College), Sw[illegible] School), [illegible] School of Medicine for Women), B. J. [illegible] Medical School), together with the [illegible] College), R. J. S. McDowall (King's College), J. Mellanby (St. Thomas's Hospital Medical School), G. W. de P. Nicholso[illegible] Hospital Medical School), H. E. Roaf (London H[illegible] E. C. Dodds, Swale Vincent, J. H. Woodger (Mi[illegible] School), B. J. Collingwood (St. Mary's Hospital [illegible] with the external examiners.

The scheme for the second medical examination Parts I and II for internal students approved in July, 1925, is to be continued for the session 1926-27.

A course of lectures on mental deficiency, supplemented by a course of clinical instruction, will be held at the central buildings of the University from May 23rd to 28th, 1927. Full particulars may be obtained from Miss Evelyn Fox, c.o. the University Extension Department, University of London, S.W.7.

The University medal at the M.B., B.S. examination for internal and external students, November, 1926, has been awarded to G. H. Steele of University College Hospital.

Applications are invited for the Laura de Saliceto Studentship for the Advancement of Cancer Research. It is of the value of £150 a year, is a part-time appointment, and may be held in conjunction with an appointment in a physiological or pathological laboratory, or clinical appointment affording special opportunities for the study of cancer. A statement of qualifications with the names of two persons as referees, one of whom should be the head of the laboratory, or the physician or surgeon under whom the candidate is working, should be sent to the Academic Registrar by July 1st, 1927.

The following have been appointed staff examiners in the subjects of examinations for medical degrees for 1927:

Bacteriology.—Dr. J. W. H. Eyre.
Forensic Medicine and Hygiene.—Dr. A. Allison and Dr. E. W. Hope.
Medicine.—Dr. C. Bolton (internal), Dr. F. R. Fraser, Dr. A. J. Hall, and Dr. C. [illegible] s: Dr. C. F. Coombs, Dr. A. G. Phear, [illegible] J. H. Bond and Dr. E. D. Macnamara.
Neurology.—Dr. Gordon M. Holmes and Dr. C. M. Hinds Howell.
Obstetric Medicine.—Dr. J. S. Fairbairn and Dr. Eardley Holland. Associate examiners: Dr. J. B. Banister and Dr. F. J. Browne.
Oto-Rhino-Laryngology.—Sir William Milligan and Mr. Herbert Tilley.
Pathology.—Sir Bernard H. Spilsbury, Dr. S. McDonald. Associate ex[illegible] lis. [illegible] annett (in [illegible] uired: M[illegible] Rock Ca[illegible] iner if required; Mr. N. C. Lake.
Tropical Medicine.—Sir P. Bassett-Smith.

UNIVERSITY OF BRISTOL.

THE following candidates have been approved at the examination indicated:

F[illegible] *Forensic Medicine and Toxicology).*—T. A. Braud, †R. M. Norman, E. A. R. Williams. (*Part I only*): L. Cleave, R. D. Jenkins, Helen B. [illegible] *Part II completing examination*): [illegible] Camps-Campins, A. M. Critchley, [illegible] R. Jackson, E. R. Wide. (*Group I only*): Helen M. Aldwinckle.

* Distinction in materia medica, pharmacy, pharmacology, and therapeutics.
† Distinction in materia medica, pharmacy, pharmacology, [illegible]

§ toxicology.

UNIVERSITY OF THE WITWATERSRAND, JOHANNESBURG.

OF the twenty-six candidates who presented themselves for the final examination for the M.B., Ch.B., in November, 1926, the following were successful in all subjects:

M. Abrams, P. Braude, Dora Dart, T. J. Faurie, Julia M. Fleming, M. Franks, F. C. Gray, R. Grieve, E. Meltzer, P. Menof, E. J. Rocher, Bella Shawsin, P. Toker, F. van den Steen.

These graduands are now eligible for registration with the various provincial medical councils. The degrees will be formally conferred on them at the University graduation ceremony next March.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary Council meeting was held on February 10th, when the President, Sir Berkeley Moynihan, Bt., was in the chair.

Diplomas.

Diplomas of Membership were granted and Diplomas in Ophthalmic Medicine and Surgery were granted jointly with the Royal College of Physicians. (The names were included in the list of licences granted by the Royal College of Physicians of London published in the BRITISH MEDICAL JOURNAL of February 5th, p. 266, and February 12th, p. 310.)

Appointments.

Sir James Berry was appointed to represent the College on the Council of the Fellowship of Medicine, in place of Mr. C. H. Fagge, who has resigned.

Sir Cuthbert Wallace was appointed Bradshaw Lecturer for the ensuing year.

Presentation.

Two silver cups, bequeathed to the College by the late Herbert William Page, M.A., F.R.C.S., "in happy remembrance of his connexion with the College as a Member of the Council and of the Court of Examiners," were presented by Mr. Low as executor.

Council Election.

An election of three Fellows into the Council will take place on Thursday, July 7th, at 10.30 a.m., in the vacancies occasioned by the retirement in rotation of Sir John Bland-Sutton, Sir Cuthbert S. Wallace, and Mr. W. Thelwall Thomas. Notice of the election will be given to the Fellows by advertisement and by circular on March 11th. The last day for the nomination of candidates will be March 21st, and a voting paper will be sent on April 5th to every Fellow of the College whose address is registered at the College.

Hunterian Lecture.

A Hunterian lecture on testicular tumours of congenital origin will be delivered by Mr. J. Howell Evans, M.D., M.Ch., F.R.C.S., in the theatre of the Royal College of Surgeons, Lincoln's Inn Fields, W.C., on Wednesday, February 23rd, at 5 p.m.

Medico-Legal.

A SUMMONS WITHDRAWN.

THE further summons taken out by the Director of Public Prosecutions against John Kynaston, retired lieutenant-colonel R.A.M.C., of unlawfully, wilfully, and falsely using the descriptions "M.R.C.S., L.R.C.P.Lond.," contrary to the provisions of the Medical Act, 1858, was withdrawn before Mr. Cancellor, at Marlborough Street police court, on February 6th. At the preliminary magisterial hearing of the summons for an offence in contravention of the Dangerous Drugs Acts it was stated by the magistrate that while the accused would be committed for trial on that summons, the further summons under the Medical Act would be adjourned *sine die*. The accused was convicted at the Old Bailey, but the Court of Criminal Appeal quashed the conviction upon its appearing that the summons was brought under rules purporting to have been made under the sanction of an Order in Council which, in fact, never existed. Mr. Evans, on behalf of the Director of Public Prosecutions, said that following proceedings elsewhere relating to the other summons, he had been instructed to ask the court to allow the second summons to be withdrawn, and to this the magistrate consented. The previous proceedings relating to the summonses were reported in the BRITISH MEDICAL JOURNAL of October 16th, 1926 (p. 716), November 20th (p. 964), and December 18th (p. 1199).

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

THE House of Commons completed the debate on the Address on February 14th, devoting the rest of the week to Supplementary Estimates and private members' business. In the House of Lords the Poor Law Bill, a measure consolidating the existing law in England and Wales, was read a second time on February 15th. Viscount Gage said the bill had obtained a second reading last year, and had been referred to a joint committee. Viscount Haldane complained that the Government did not tell the House when the larger measure of Poor Law reform would be introduced.

On February 14th, at the House of Commons, the Medical Committee of the Central Association for Mental Welfare met members of Parliament who are specially interested in the Mental Deficiency Bill, which has won a good place in the ballot. The text of the bill will not be available much before March 18th, the day chosen for the second reading debate, but, as explained by Sir Leslie Scott, who was in the chair at the meeting on February 14th, the text of last year's bill, as amended by a Select Committee of the House of Commons, will be followed, with the exception that the definition of mental deficiency is to be amended. The loss of the bill last session was chiefly due to lay and legal objections against this definition. The meeting on February 14th agreed that to overcome these objections a definite age (18 years) should be put in the bill as the maximum age at which a person could be certified as mentally defective. Medical opinion was unanimous against fixing any legal age, but the meeting agreed that if an age must be inserted in the bill 18 years would be likely to suit all views. Dr. Shrubsall, speaking with experience of all the schools of London, said very few young persons became mentally defective between the ages of 16 and 18. There was a strong feeling in the meeting that "moral imbecility" should be deleted from the list of grounds justifying certification, as such cases would come under the other categories, in particular feeble-mindedness. No decision to delete was taken, however, and "moral imbecility" will probably remain in the bill as printed and presented to the House. A member who will share in presenting the bill to the House on second reading spoke of the desirability of preventing, either by segregation or surgery, the propagation of the feeble-minded, but the meeting decided that to incorporate such a proposal would destroy the chances of the bill. The meeting was attended by several alienists and women doctors, and, among other members of Parliament, by Dr. Fremantle and by Major Cadogan, who spoke for those interested in the Borstal system.

The Parliamentary Medical Committee met for the first time this session on February 18th to arrange procedure for the session and to hear statements from medical members who accompanied the parliamentary delegations to Australia and Malta.

The Executive Committee of the Unionist Health and Housing Committee met, Dr. Fremantle presiding, on February 15th, to arrange its programme for the session.

Bills.

In the House of Lords, on February 15th, Viscount Astor introduced the Education (Employment of Children and Young Persons) Bill, which was read the first time.

Bills presented in the House of Commons include a Mental Deficiency Bill "to amend certain enactments relating to mental defectives." This is presented by Mr. Crompton Wood, supported by Sir Douglas Newton, Sir Leslie Scott, Mr. Rhys Davies, Mr. Cadogan, Dr. Fremantle, Dr. Haden Guest, Lord Apsley, and Mr. Geoffrey Peto. It is set down for second reading on March 18th. An Optical Practitioners (Registration) Bill, presented by Mr. West Russell, is down for second reading on May 13th. A Factories Bill, prepared by the Labour party and presented by Mr. Tinker, is set down for second reading on May 27th. A Nursing Homes (Registration) Bill is presented by Mrs. Philipson (second reading April 1st), and a Midwives and Maternity Homes (Scotland) Bill by Mr. Barclay Harvey (second reading March 18th). These last two may not be reached on the dates appointed, but should receive a second reading on other dates. A Maternity Benefit Bill "to extend maternity benefits to mothers in cases of miscarriage" is introduced by Sir Hugh Lucas-Tooth, supported by Dr. Vernon Davies, Dr. Watts, and other members.

Experiments on Dogs.—In the House of Commons, on February 14th, Sir Robert Gower (Hackney, Central, U.) presented a bill to prohibit the vivisection of dogs, and it was read a first time. It was put down for second reading on April 29th. On the same day the Home Secretary told Mr. Bromley (Barrow-in-Furness, Lab.) that he had received a resolution, passed at a public meeting, asking the Government to empower the police to grant a permit to anyone who had lost a dog to visit and inspect the kennels and animal houses attached to establishments where vivisection was practised. The Home Secretary said that he had no power to authorize the grant of such permits. Replying further to Mr. Bromley, the Home Secretary said that the idea of such permits was a good one. Perhaps Mr. Bromley would ballot for a bill on the subject.

Motions.

In the House of Commons, on February 15th, Dr. Watts gave notice that in Committee of Supply on the Civil Service Estimates he would call attention to the serious outbreaks of small-pox and move a resolution. Dr. Fremantle, on behalf of Major Tasker, gave notice to call attention on the Naval Estimates to the increased need of scientific research.

Treatment of Physically Defective Children.—On February 14th the Duchess of Atholl (Parliamentary Secretary to the Board of Education) stated that in thirty-five areas local authorities so far had made no provision for physically defective children, but in some of these areas voluntary agencies were at work. The Education Minister did not think that further action on his part was required at present. The education of children of school age who were suffering from more than one defect was receiving careful attention. Replying to Mr. Cave, the Duchess of Atholl said that a circular just published did not state that the President of the Board of Education would not allow local authorities to provide schools for defective children, nor was that his intention. The circular merely drew the attention of the authorities to the question of the completion of the medical services, which was of primary importance.

Spahlinger Treatment.—Mr. Neville Chamberlain states that the offer made to M. Spahlinger by the Ministry of Health is still open. This is to arrange for a scientific investigation in this country of his methods of treatment as soon as the necessary materials are forthcoming. Mr. Chamberlain is not at present in communication with M. Spahlinger.

Use of Poisons and Bacteria in War.—On February 15th Mr. Baldwin, in reply to Mr. James Hudson, said that until a definite assurance could be obtained that all the Powers were willing to adopt prohibitive measures against the military use of poisons and bacteria, the British Government must take steps to be in a position to defend itself against such attacks. Answering another question on the same day, Sir L. Worthington Evans said no animals had been used for experimental purposes in the Chemical Warfare Research Station at Sutton Oak.

African-born Medical Officers.—On February 14th Mr. Amery (Secretary for Dominion Affairs), told Sir Cooper Rawson the Government's policy was that natives of West Africa, who were qualified medical men and otherwise suitable for public employment, should be employed in the Government service there. In the Gold Coast, out of a total medical staff of sixty-seven, three were Africans. The Colonial Government must make the best use of the staff at its disposal, and he could not see his way to interfere with the Governor's exercise of his discretion. Sir Cooper Rawson raised this question in consequence of a proposal to appoint a native doctor to succeed a European doctor at Dunkwa, Gold Coast Colony, where there are over forty European residents.

including women, the nearest European doctors being at Sekondi and Kumasi, six and a half and four and a half hours away respectively.

Pensions.—Major Tryon told Mr. Robinson that experience of the past year had shown that where old wounds inflicted in the war had broken down more than seven years after discharge the cases were, for the most part, restored by treatment. If in any such case the man, after treatment, was found to be seriously incapacitated, the making of an appropriate grant was considered. In a case where a first application in respect of a shrapnel wound had not been made till more than seven years after discharge treatment had been provided.

Factories Bill.—Answering Mr. P. J. Hannon, on February 10th, Sir William Joynson-Hicks said the Government had decided to introduce the Factories Bill at the beginning of the next session in November next, so that it could be read a second time before Christmas and pass into law in 1928. He expected during the next few months to receive deputations from manufacturers and organizations of workers.

Notes in Brief.

In the year ended March, 1925, the average weekly cost of maintaining lunatics at institutions at the charge of the guardians in England and Wales was 21s. 3½d. a head, and the average weekly cost of persons in Poor Law institutions 27s. 1½d. a head.

Importers of milk have to be registered and may be struck off if they import milk which does not comply with the Public Health (Imported Milk) Regulations. The amount of milk imported into England and Wales is negligible.

The Minister of Health is communicating with the London County Council about the provision of open spaces in London.

Thirteen outbreaks of foot-and-mouth disease were confirmed between January 1st and February 10th. In 1926 there were 204 outbreaks.

Additions have been made to the sanitary staff in Tanganyika Territory, and the training of native assistants and nurses is making rapid progress.

No bill dealing with slum clearances will be introduced by the Government this session.

One of the medical inspectors of the Home Office will, at an early date, investigate the incidence of lead poisoning in potteries using low solubility glazes. In the years 1916-26 cases of lead poisoning reported in such potteries numbered sixty-seven; sixty of these persons had previously been employed in factories using raw lead glazes.

In 1923-24 the expenditure on maternity and child welfare in England and Wales was £791,000; in 1924-25 it was £814,000; and in 1925-26 £897,000. The expenditure on the treatment of tuberculosis in the same periods was £1,337,000, £1,430,000, and £1,547,000 respectively; and in grants towards the provision of sanatoriums £87,000, £15,000, and £19,000. The expenditure on the treatment of venereal diseases was £303,000, £298,000, and £307,000; and on welfare of the blind £83,000, £95,000, and £104,000 respectively.

San Salvador has ratified the International Opium Convention.

In 1925 no deaths in any London hospital were certified as from tetanus following dog bites. Later figures are not available.

The percentage of recruits discharged from the army for medical reasons within three months of enlistment during the year ended September 30th, 1926, was 2.18.

Medical News.

AT the social evening of the Royal Society of Medicine on Monday next Mr. Percy Flemming, consulting ophthalmic surgeon to University College Hospital and to the Moorfields Hospital, will give an illustrated address consisting of topographical and medical notes on "Harley Street," at 9.30 p.m. Fellows and guests will be received by the President and Lady Berry at 8.30, and there will be an exhibition of prints and maps of the neighbourhood of Harley Street, lent by the London County Council, University College, the Wellcome Historical Medical Museum, Mr. Francis Edwards, and others.

THE International Society of Hydrology, whose president is Dr. Gustav Monod of Paris, will hold a conversazione at the rooms of the Medical Society of London on the evening of Thursday, March 3rd, when Mr. Lewis Abbott, F.G.S., will give a demonstration with the epidiascope on hydration and dehydration, the life history of silica from the colloid to the crystalline, including the birth, life, and death of the opal. Exhibits of hydrological interest from the Wellcome Historical Medical Museum will be on view. Representatives from France, Germany, Italy, Czecho-Slovakia, Holland, and Belgium have accepted the invitation. Any members of the medical profession who would like to attend are invited to communicate (by letter) with Miss Fox, 139, Marylebone Road, W.1.

AT the meeting of the Harveian Society to be held at the Paddington Town Hall, W., on Thursday, March 10th, at 8.30 p.m., Sir Berkeley Moynihan, Bt., K.C.M.G., C.B., President of the Royal College of Surgeons of England, will deliver the Harveian Lecture on diverticula of the alimentary canal.

THE Hunterian Oration before the Hunterian Society of London will be delivered by Mr. Girling Ball, at the Cutlers' Hall, Warwick Lane, E.C., on Monday, February 28th, at 9 p.m. The subject is "The value of modern methods of investigation in the diagnosis and treatment of haematuria."

THE Oxford Ophthalmological Congress will assemble at Keble College on the afternoon of July 6th, and the meeting will be held on the three following days. On the morning of July 7th a discussion on the results of the operative treatment of glaucoma will be opened by Dr. W. H. Wilmer, ophthalmologist-in-chief of the Johns Hopkins Hospital, Baltimore. The Doyne Memorial Lecture will be delivered on the morning of July 8th by Professor K. K. K. Lundsgaard of Copenhagen, the subject being "The pneumococcus in connexion with ophthalmology." One afternoon will be devoted to demonstrations in the scientific and commercial museums, and members are invited to exhibit pathological specimens, instruments, and apparatus. The official dinner of the congress will be held on the evening of July 7th in the hall of Keble College. Members who desire to take part in the discussion, or to contribute papers or specimens, should notify the honorary secretary, Mr. Bernard Cridland, Salisbury House, Wolverhampton, as soon as possible.

AT a meeting to be held on February 23rd, at 6.30 p.m., at the Royal Institute of British Architects, 9, Conduit Street, W.1, Mr. G. F. Barwick, late keeper of printed books at the British Museum, will give an address on the *Directory of Sources of Specialized Information* now being compiled by him for the Association of Special Libraries and Information Bureaux. Before the address there will be an informal discussion on public and special libraries: their spheres of service and potential relationship.

DR. G. A. SUTHERLAND will lecture for the Fellowship of Medicine on February 24th on fits and faints, at 5 p.m., at the Medical Society, 11, Chandos Street, W., and on February 23rd Mr. Gimblett will give a lecture at the Royal Westminster Ophthalmic Hospital on affections of the cornea. Dr. Wylie will give a special demonstration at the Central London Throat, Nose, and Ear Hospital on February 24th at 2 p.m. This demonstration and the two lectures are free to all members of the medical profession, but in the last case notice of intention to attend should be sent to the hospital secretary (Museum 1539). Beginning on March 7th, the Brompton Hospital will hold a six-day course of instruction, including demonstrations in artificial pneumothorax, radiology, and the use of the cardiograph. The Chelsea Hospital for Women will hold a course from March 14th to 25th, and there will be a comprehensive course at the Royal National Orthopaedic Hospital from March 21st to April 2nd. During the same fortnight there will also be a course, primarily for the general practitioner, at the Lot
in the late afternoon. From Mar
Queen's Hospital for Children will
A series of demonstrations on diagnosis and treatment will be given at the Royal Eye Hospital for the two weeks beginning March 28th. The Fellowship arranges practical courses in anaesthetics and courses in obstetrics; arrangements are also made for clinical assistantships in gynaecology. Copies of all syllabuses and of the *Post-Graduate Medical Journal* may be obtained from Secretary of the Fellowship, 1, Wimpole Street, W.1.

THE programme of the Post-Graduate Hostel at the Imperial Hotel, Russell Square, W.C.1, for next week includes an address on Wednesday, at 9 p.m., by Mr. H. W. Carson, on ulcers of the lesser curvature, and on Thursday a symposium on ulcers of the tibia, under the chairmanship of Sir D'Arcy Power. Dinner (5s.) will be served at 8 p.m.

AN intensive post-graduate course will be held at the Great Northern Hospital, Holloway Road, N., during next week. Afternoon lectures will be given as follows at 2.15 and 3.15 p.m.: February 21st, Dr. Reynell, Anxiety neuroses; Mr. Kenneth Walker, Treatment of prostatic obstruction. February 22nd, Dr. McNee, Diseases of biliary tract; Mr. Zamora, Carcinoma of larynx. February 23rd, Dr. Semon, Diagnosis of skin diseases; Mr. Hunter, Surgery of the chest. February 24th, Dr. Bruce Williamson, Drugs in heart disease; Mr. Lane Roberts, Obstructed labour. February 25th, Mr. Sauer, Cancer of rectum; Mr. Gimblett, Points of general interest in eye diseases. The entire work of the hospital, between 10 and 12, will be open to those attending. The course is free, and tea will be provided at 4.15 p.m.

AN afternoon post-graduate course in cardiology will be held at the Liverpool and District Hospital for Diseases of the Heart during the fortnight beginning March 7th. The fee for the course is one guinea; the number taking the course is limited to twenty. Application should be made to Professor Beattie, at the hospital, 34, Oxford Street, Liverpool.

THE Scottish Board of Health has renewed for one year the regulations with regard to the notification of infective jaundice.

AT a meeting of the Central Midwives Board for England and Wales, on February 3rd, Hammersmith and Lewisham Hospitals were approved as training schools. A letter was sent to a midwife informing her that when a doctor was in charge of a case the responsibility for it was his, and that the midwife must faithfully obey his instructions. In reply to a question from a medical officer of health it was stated that under the new rules the form for keeping ante-natal notes must be the one approved by the Board, though the local supervising authority would be permitted to exhaust any stock of the previously used type of ante-natal registers.

AT the thirteenth annual general meeting of St. Andrew's Hospital, Dollis Hill, for the professional and middle classes, when Cardinal Bourne was in the chair, it was reported that £30,000 is required for the provision of additional beds, the opening of a children's ward, and a home for the nurses and staff. The amount that has so far been contributed is £4,600, and an appeal was made for £15,000 to enable the building to be started immediately according to plans approved by King Edward's Fund. The hospital was opened in 1913, and although contributions are asked from patients who can afford to pay, no patient, it is stated, has ever been refused, whatever his nationality or creed, solely on the ground that he could not pay a fee.

SOME years ago—it seems a good many—Dr. Leonard Hill, F.R.S., exhibited a number of his own pictures; the collection seemed to prove that in art, as in science, he was specially interested in phenomena of air and light. He has now arranged a larger one-man show containing upwards of 120 works, most of them in oil, but others in water-colour and pastel. Some of them are elaborate pictures, others sketches, or, as it were, passing notes of colour effects. The water-colours are perhaps the most successful. The exhibition is being held at the Alpine Club, Savile Row, and will remain open until February 25th. It is well worth a visit.

AT the recent by-election in the Streatham Division Dr. James Kirkland was returned to the Wandsworth Borough Council, polling 3,638 votes in the Municipal Reform interest, against 520 and 328 recorded respectively for the Labour and Progressive candidates.

THE Henry Saxon Snell prize of the Royal Sanitary Institute, which is awarded every three years, will in 1927 consist of fifty guineas and the medal of the Institute; candidates must submit an essay on "Sanitary accommodation, appliances and fittings, for hotels and flats, with suggestions as to proper placing, arrangement, ventilation and lighting, particularly where there are no external walls in which windows can be placed." Essays must be sent on or before September 30th, 1927, to the secretary of the Royal Sanitary Institute, 90, Buckingham Palace Road, S.W.1, from whom further information may be obtained.

THE late Sir John Sherburn, M.B., C.M., a former mayor and sheriff of Hull, and consulting surgeon to the Hull Royal Infirmary, has left estate valued at £144,583. He was a partner in the shipping firm of Bailey and Leatham.

THE Cambridge University Press announces that it will publish early next month a book by Dr. Bernard Hart entitled *Psychopathology: Its Development and its Place in Medicine.* The text will be founded on the Goulstonian Lectures of 1926.

THE first number of the *British Journal of Tuberculosis* appeared in January, 1907, so that its January issue is the coming-of-age number. A symposium of congratulatory comments includes contributions from Sir George Newman, Sir Arthur Newsholme, Sir Humphry Rolleston, Sir Robert Jones, Dr. Rollier, and others. In this issue Dr. Varrier-Jones describes, with illustrations, the Papworth tuberculosis colony, and Dr. Muthu gives a general survey of tuberculosis in India. An account of the American National Tuberculosis Association is supplied by its publicity director, Dr. P. P. Jacobs.

FOUR German universities will celebrate the anniversary of their foundation this [illegible]g, founded 1402 (exact date unknow[illegible] 9th, 1447; Marburg, May 30th, 1527; [illegible] 15th, 1702.

WE have recently received the special number of *Bruxelles Médicales* devoted to the congress held at Brussels from June 26th to 30th under the name of *Journées medicales de Bruxelles.* The issue contains numerous illustrations, including photographs of prominent members of the congress.

AT the end of January a medical congress entitled Journées Médicales was held at Nancy, and was attended by Professor Forman, director of the Anticancer Institute of Luxemburg, and many physicians and surgeons of the surrounding provinces. Professor Vautrin, director of the Nancy Anticancer Institute, gave an address in which he denied that cancer was inherited or incurable. He emphasized the value of the work performed by various anticancer institutes, with especial reference to radium treatment.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the BRITISH MEDICAL JOURNAL must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, *on receipt of proofs.*

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the JOURNAL, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the BRITISH MEDICAL JOURNAL are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Mediscern Westcent, London.*

The address of the Irish Office of the British Medical Association is *16,* South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

QUERIES AND ANSWERS.

"B. B." asks whether ionization in a case of chronic otorrhœa of thirty years' standing is likely to cure or alleviate the condition, and, alternatively, whether this treatment would be likely to do any damage to the ear.

EPIPHORA.

DR. A. C. BALFOUR (Aviemore) writes: If "G. A." (Norfolk) will use a lotion of adrenaline chloride (P., D. and Co.) 1 in 8,000 I think his case of epiphora will improve. It only requires one or two drops two or three times a day.

RECURRENT TONSILLITIS.

DR. F. PEARCE STURM (Leigh, Lancs) writes: "Scrutator's" patient (BRITISH MEDICAL JOURNAL, February 12th, p. 312) possibly suffers from infection of the granulation masses containing extra-capsular lymphoid tissue, which occasionally grow in the tonsillar fossæ after the most skilful enucleation of the tonsils. They are very troublesome, and if removed tend to recur with a persistence whic[illegible]al malignancy. Beck of Chicago (*Applied [illegible] the Nose, Throat, and Ear*, London, 1923) states that the condition is easily controlled by electro-thermal [illegible] tor's" patient required the removal o[illegible] years, she probably has some deficie[illegible] iggest, therefore, a trial of parathyr[illegible] local application of Dundas-Grant's paint: Iodine 6 grains, acetic ether 2 drachms, and glycerin 6 drachms.

INCOME TAX.

Assessment of Income.

"FIDUS" holds a part-time appointment and commenced private practice at his residence as from February 8th, 1926. His first year's takings amounted to £51, and the "expenses of practice, of course, exceed this." His inspector of taxes says he must include the annual value of the house, which he owns, and that he cannot deduct the amount of his professional loss from the assessment of his salary.

*** It is correct that the annual value must be included in the statement of his total income. The assessment of his salary must be dealt with as a matter separate from the private practice, but if he makes a loss on the latter he is entitled under Sec. 34, Income Tax Act, 1918, to an adjustment accordingly for the same year. In computing the result of his practice, however, the capital outlay in starting will have to be excluded from the expenses, and it is unlikely in all the circumstances that he will be allowed to deduct one-half the general cost of rates, wages, telephone, and "rent"—the rent being the amount on which he is assessed as owner. Further, the cash basis is inapplicable to a new practice, and he will have to bring into the computation of the first year's profits the value of the book debts due to him at the end of the year.

"S. C." seeks advice as to how he should declare his income from property and shares in his statement of total income.

*** Such income is returnable on the basis of the amount received in the year of assessment. When changes in ownership are involved, or are likely to be, it is advisable, unless the amount of the total income is immaterial, to state the facts

briefly in a note accompanying the return. Where property is concerned, the amount of the income to be included is correctly the proportion of the annual value, according to the period for which the property has been owned, in the year for which the return is made.

Information as to Capital.

"L. C." inquires whether the income tax authorities are entitled to information as to the source of the *capital* which he put into the purchase of a practice.

*** The authorities are concerned with the proper assessment of "L. C.'s" *income* either for the present or any previous year as far back as April 5th, 1920, and we cannot see any grounds on which they could claim that the source of his capital was relevant to his assessment. If not relevant they have no right to a reply, and if the inquiry is put and pressed "L. C." might write again after ascertaining the grounds for the inquiry.

Cash Receipts Basis.

"KLAXON" has taken over a practice as from October, 1926, and has been informed by the local authorities that for the half-year to April, 1927, he will have to pay on one-half of his predecessor's assessment and that he will be assessed in future on the basis of his book debts.

*** As regards the first point, the position is that he is liable to be assessed according to his predecessor's past average profits—that is, on one-half of the gross assessment so calculated, less all the personal allowances which may be due to him. If, however, "Klaxon" can show that the earnings of the practice fell short from some specific cause since or by reason of his succession, then he will be entitled to have the assessment for the six months to April, 1927, adjusted to the amount of his earnings. If such an adjustment is probably due, no doubt he can arrange with the inspector of taxes for the assessment to remain in abeyance until after March. It is assumed that "Klaxon" is not collecting his predecessor's accounts and bringing them into his own income tax returns, in which case the cash receipts would not reflect the full gross earnings of the practice and would properly be refused; but he should claim a reasonable allowance for outstanding debts likely to be wholly or partially irrecoverable.

Motor Car Transactions.

"E. J. B." bought an "R" car in 1921 for £273 and sold it in 1923 for £90, buying an "F" car for £160. He sold that car in 1926 for £15, buying an "M-O" car for £362.

*** The amounts to be claimed as *expenses* are as follows: (1) of the year 1923, £160−£90=£70; (2) of the year 1926, £362−£15=£347, less the excess of the gross cost (£362) over the original car outlay (£273)—that is, a net amount of £347−£89=£258. For the financial year 1926-27 he should also claim a depreciation allowance of 20 per cent. of £362=£72.

"M. H.'s" car transactions have been as follows: In 1915 he purchased a second-hand "S" car for £335 and sold it in 1927 for £30; he bought a new "St." car in 1925 for £275 and sold it in December, 1926, for £128; in July, 1926, he bought a second-hand "V" car for £320, which he is still using.

*** In our opinion the renewal or obsolescence claim is best made as for the year definite figures are ascertainable—that is, the year of sale. On that basis "M. H." should claim as follows: (1) "S" car, renewal cost as an expense of the year 1927, £335−£30=£305. (2) "St." car, obsolescence allowance, £275−£128=£147, deduct depreciation allowance given (that is, 20 per cent. of £275=£55), net claim £92, as an expense of the year 1926. (3) "V" car, 20 per cent. of £320=£64 as a depreciation allowance for 1927-28. The authorities may claim to restrict the above to allow for the falling value of cars generally on the ground that there was some loss of capital. If so perhaps "M. H." will send us their figures.

LETTERS, NOTES, ETC.

ACQUIRED MELANISM IN MOTHS TRANSMITTED BY INHERITANCE.

SURGEON REAR-ADMIRAL CHARLES M. BEADNELL, R.N.(ret.), writes: With reference to the note in the BRITISH MEDICAL JOURNAL of February 5th on acquired melanism in moths transmitted by inheritance, may I protest against the easy assumption that an "acquired melanism" had been proved by Dr. Heslop Harrison to be "transmissible by inheritance" on the basis of the alleged fact that certain moths fed in their larval stages on a lead-manganese contaminated diet begot, as descendants, melanized moths the larvae of which had been fed entirely on uncontaminated food. The expression "acquired melanism" would appear to me to beg the question. Sir Archdall Reid, who, more than any biologist past or present, has shown the confusion of thought, through faulty terminology, that has accompanied the long and heated controversy concerning the transmission of acquired characters, defines an acquired character as one developed under the stimulus of *use or injury* in contrast to an inborn character which is one developed under the stimulus of *nutriment*, inheritance being, according to this authority, the reproduction, as a nutritional character, by the offspring of a parental character of any sort. Now I submit there is no evidence in the case in point of any use or injury stimulus having called forth a deposition of pigment in the hypodermal cells of the metal-fed moths. On the other hand, it is surely obvious that a nutriment stimulus was present and that it was this that produced in the moths the inborn character melanism which, happening to be a variation in a direction favourable to the industrialized environment of the insects, was fostered and furthered by natural selection and reproduced as a nutritional character by descendants. In short, it was, I submit, the germ plasm of the moths that was directly acted upon by the circulating manganese and lead salts. If, at any point in the eighty odd million year line of germ cells of the multicellular organisms, the germ-plasm be affected by nutritional or mechanical stimuli to the point of definite structural adjustments, there would be brought about in descendant germ cells the potentiality (temporary or permanent according to the survival value) to induce related structural adjustments in certain groups of cells of that ephemeral excrescence on the germ cell that we term the *body*.

HERPES ZOSTER AND VARICELLA.

DR. H. TAYLOR (Banbury) states that in December, 1926, he attended a man who was suffering from a severe attack of herpes zoster. Ten days later, when the herpes was drying up, he was called to the patient's wife, who was suffering from a severe acute form of chicken-pox. Neither of the two patients had been away from the village for several weeks previously, and there had been no other case of herpes or varicella in the neighbourhood. Although the baby in the family had been in contact with the father during the acute herpes eruption, it escaped entirely.

JUDICIAL HANGING.

"EX-COLONIAL SURGEON" writes: Early one morning a few years ago I had to witness the execution of four coloured men in a gaol. As it happened, the executioner was anxious to finish his work as soon as possible in order to catch a train, and the scaffold held two at a time, so they were divided accordingly. When the first pair were hanged it was my duty to determine the fact of death. As a general rule, on auscultation the heart may be heard beating for about ten minutes after the drop, and on this occasion, when the sounds had ceased, there was nothing to suggest any vital spark. The bodies were cut down after fifteen minutes and placed in an ante-chamber, when I was horrified to hear one of the supposed corpses give a gasp and find him making spasmodic respiratory efforts, evidently a prelude to revival. The two bodies were quickly suspended again for a quarter of an hour longer. The executioner, who was thoroughly experienced, had done his part without a hitch, and the drop given was the regulation one according to individual physique. Dislocation of the neck is the ideal aimed at, but, out of all my *post-mortem* findings, that has proved rather an exception, while in the majority of instances the cause of death was strangulation and asphyxia. One such gruesome incident seems to me enough to condemn hanging in any civilized country.

*** The nature of death by judicial hanging has been discussed at intervals during the last fifty years, and Dr. J. de Zouche Marshall, who took much interest in the subject, wrote in our issue of November 15th, 1913 (p. 1341), to suggest that the time had come for further inquiry, since the recommendations of the Aberdare Committee of 1886, with reference to the length of the drop, were not being followed. General opinion at present is to the effect that with an expert hangman, using the submental knot, death is due to fracture dislocation of the axis vertebra and severing of the spinal cord, as described by F. Wood-Jones in the *Lancet* in 1913. With the subaural knot death by strangulation or fracture of the base of the skull seems to be more likely.

JOHN LEYDEN.

[illegible] writes: At the close of your most [illegible] medical man and orientalist [illegible] you remark: [illegible] is perfectly true, but inasmuch as his name occurs at the end of a beautiful stanza in "The Lord of the Isles," there is less excuse than otherwise for this neglect. Just before going out to India Leyden visited the Inner Hebrides, and thus Scott wrote of—

> "Scenes sung by him who sings no more,
> His bright and brief career is o'er
> And mute his tuneful strains;
> Quenched is his lamp of var ed lore,
> That loved the light of song to pour;
> A distant and a deadly shore
> Has Leyden's cold remains."
>
> "Lord of the Isles," Canto IV, Stanza XI.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 40, 41, 42, 43, 46, and 47 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 44 and 45.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 63.

EPITOME OF CURRENT MEDICAL LITERATURE.

Medicine.

190. Latency in Syphilis.

J. H. STOKES (*Brit. Journ. Vener. Dis.*, October, 1926, p. 289) considers that the interpretation and management of latency in syphilis depend upon complete examination repeated at intervals during life, and that latency as defined in terms of the Wassermann reaction alone has no significance for the patient. Since it appears to be impossible to define the amount of treatment which should be given to a patient with a persistent Wassermann reaction, Stokes advocates as guiding principles in treatment that every accessible organ and tissue should be examined by every available clinical method for evidence of syphilitic changes, and that the degree of activity, extent of damage, and probable recuperative power of the most vital structure involved by the infection should be thoroughly investigated. The aim should be, after estimating the tolerance for arsenic and mercury of the liver, kidneys, and skin, to increase such tolerance by protective measures, and the removal of focal infection, in order to obtain a satisfactory symptomatic response of those structures involved by the disease within the limitation of the weakest element in the tolerance, and, if possible, to give as much treatment as to a fully developed secondary case. Stokes suggests a tentative maximum schedule of four courses of eight weekly injections of arsphenamine with three courses of bismuth or mercury intramuscularly, 100 to 150 inunctions, and 20-grain doses of iodide by mouth before meals. It is important that when once treatment has been begun it should be performed thoroughly, as otherwise it is better to limit the treatment to mercury, iodide, and bismuth rather than to start an inadequate arsphenamine therapy which cannot be continued till it results in complete and persistent Wassermann negativity. If the initial treatment has been thorough the question of lifelong intermittent treatment in the presence of a persistent positive Wassermann reaction is one for decision in each individual case, depending upon the type of involvement found before the process came to apparent quiescence. Short courses of arsphenamine injections or insufficient mercurial treatment are deprecated as being half measures likely to be harmful.

191. The Heart in Thyroid Disease.

E. P. BOAS (*Med. Journ. and Record*, December 1st, 1926, p. 695) states that in simple goitre cardiac hypertrophy is usually constant and proportional to the size of the goitre; it appears to be due to the increased vascularity of the thyroid in the earlier stages, to mechanical pressure, and to increased blood pressure. It has also been attributed to toxic influences. The hypertrophy may diminish after operation, but ordinary cardiac therapy is of little avail, and digitalis is usually ineffectual. In exophthalmic goitre there is often moderate hypertrophy and dilatation of both ventricles, with fatty infiltration. Extensive myocardial necrosis without evidence of myocarditis or of coronary lesions has been described. These lesions are probably toxic. Disorders of the cardiovascular system are among the most important symptoms of Graves's disease. Digitalis is useless in the tachycardia until arrhythmia occurs, but when auricular fibrillation and myocardial insufficiency appear the treatment is that of ordinary heart disease. With auricular fibrillation sufficient doses of digitalis should be given to reduce the pulse rate to approximately 72. These patients are particularly subject to the cerebral toxic effects of digitalis. The author strongly recommends quinidine hydrochloride in auricular fibrillation in exophthalmic goitre. In myxoedema the heart is usually normal. Boas adds that some writers have recorded large hearts in myxoedematous patients which receded rapidly in size after administration of desiccated thyroid, but says that this remedy should be given cautiously, since many of these damaged hearts cannot withstand the strain of the sudden increase of general metabolism.

192. Prolonged Chorea.

P.-F. ARMAND-DELILLE and J. IBERT (*Bull. et Mém. Soc. Méd. des Hôp. de Paris*, December 16th, 1926, p. 1694) report the case of a child, aged 4 years, who for six months has been in a choreic state, characterized by involuntary movements of a somewhat peculiar type, these being slight, irregular, and frequent. There are no points of importance in the antecedent history of the child or its parents, both of whom are healthy. Movements of the head to the right and left are sometimes extreme, and movements also involve the lips, the shoulders (particularly the right), the fingers, the thighs in flexion, and the feet in adduction. The diaphragm is unaffected. While voluntary movement of the lower extremities is normal, the gait seems to be difficult and hesitant. There is no alteration of the reflexes, sensibility, or psychic state. The eyes show a certain degree of functional paralysis of convergence and a slight exophthalmos. The cerebro-spinal fluid contains a normal amount of albumin, but a marked increase of sugar; there is no leucocytosis, and a negative Wassermann reaction, which is, however, weakly positive in the blood. The other organs are normal, and there are no cardiac changes or urinary abnormalities. Treatment with Boudin's liquor and sulpharsenol does not modify the movements. As chorea is one of the sequelae of epidemic encephalitis the authors incline to this diagnosis, but the blood Wassermann reaction has raised the possibility of congenital syphilis.

193. Control of Scarlet Fever.

W. COLBY (*Journ. Amer. Med. Assoc.*, September 18th, 1926, p. 919) states that the process of active immunization against scarlet fever has been made mild, safe, and rapid by proper neutralization of the raw toxin with sodium ricinoleate. By such a method 87 per cent. of children under 8 years of age, and as high as 77 per cent. of older children susceptible to scarlet fever, have been made Dick-negative in eight days. On the occurrence of three cases of scarlet fever in a school for the deaf 272 children, whose ages ranged from 6 to 18 years, were tested by Dick's method; 76 proved positive, and were immediately injected in the deltoid muscle with scarlet fever streptococcus toxin in a 2 per cent. solution of sodium ricinoleate, so that the concentration of the toxin was 3,000 skin test doses per cubic centimetre. A second injection was given a week later with a concentration of 5,000 skin test doses per cubic centimetre neutralized by a 2 per cent. sodium ricinoleate solution. Local reactions were few and mild. Only two patients had general reactions, consisting in slight fever and headache for twenty-four hours. One case of scarlet fever developed in a patient with a positive Dick reaction five days after the first injection. No case occurred after the second injection. Three months later 32 of the 36 girls immunized (88 per cent.) and 23 of the 38 boys (60.5 per cent.) were negative. The lower percentage of negatives in the boys was due to the fact that most of them were 15 years of age or over, which tended to confirm the previous observation that older children and young adults are not so readily immunized as younger children. In view of the fact that mild scarlet fever may occur in cases with a negative Dick reaction Colby argues that the strength of the test material should be increased.

Surgery.

194. Fracture of the Semilunar Carpal Bone.

ADNET and PANIS (*Bull. et Mém. Soc. Nat. de Chir.*, January 1st, 1927, p. 1229) report a case of fracture of the semilunar carpal bone. The patient fell on his hand and was treated, by splinting, for a fracture of the lower end of the radius. Three months later, when examined again, he was found to have marked limitation of movement at the wrist and some swelling. Radiograms at this time showed a united fracture of the styloid process of the radius and a fracture of the semilunar into three fragments, which were united in bad apposition. In view of this fact and the limitation of movement at the wrist-joint it was decided to excise the semilunar bone. The incision was made on the dorsal aspect and the bone was removed after considerable difficulty owing to its attachments and the irregularity of the callus formation. The result of the operation was extremely satisfactory, and the movements were very greatly increased. The authors believe that the loss of movement was probably due to the faulty position of the fragments of bone rather than to an arthritis in the wrist-joint.

195 Statistics of Renal Tuberculosis.

G. MATRONOLA (*Arch. Ital. di Urol.*, October, 1926, p. 129) gives the following statistics of 125 cases of renal tuberculosis observed at the Institute of Clinical Surgery of the University of Rome. In 93 cases, or 73 per cent., the ages of the patients were between 20 and 40; only 9 were less than 20 and 8 older than 50; 58 patients were males and 67 females. In 54 the right kidney, in 59 the left kidney, and in 12 both kidneys were affected. The initial symptoms were as follows:

vesical symptoms such as pollakiuria, strangury, and pyuria in 53, lumbar pain in 40, haematuria in 15, general weakness in 8, nothing definite in 9. Fifty-one patients showed pre-existing or concomitant tuberculous lesions elsewhere, involving the pleura, lungs, bones and joints, peritoneum, epididymis, lymphatic glands, or larynx. Out of a total of 104 patients who underwent operation 14 died before leaving hospital, death being due in 6 cases to renal insufficiency, in 3 to infections, in 2 to tuberculous meningitis, and in 3 to causes not stated. Of 54 patients who could be subsequently traced 39 were still living and 15 had died after intervals ranging from ten years to less than a year, the causes of death being as follows: probable tuberculosis of the other kidney in 9, pulmonary tuberculosis in 2, tuberculosis of bone in 1; in 3 the cause was unknown. Of the 39 survivors of whom details could be obtained the time which had elapsed since their operation ranged from two to fourteen years; 27 showed no symptoms whatever and the remainder presented more or less intense pollakiuria, pyuria, or haematuria.

196. Splenectomy in Henoch's Purpura.

B. MYERS, A. K. GORDON, and R. MAINGOT (*Brit. Journ. Child. Dis.*, October–December, 1926, p. 241) report a case of Henoch's purpura, in a girl aged 6, characterized by purpuric spots on the arms, legs, and face, vomiting, haematemesis, melaena, and persistent haematuria. All medical treatment failed to stop the haematuria. Laboratory tests showed (1) that the blood platelets underwent progressive reduction, (2) that the polymorphonuclear leucocytes were similarly affected, (3) that evidence of bacterial toxaemia was absent, and (4) that while a slight degree of secondary irritation was present the primary lesion was haemorrhage and not nephritis. As the evidence tended to implicate the spleen splenectomy was performed, and was followed by complete and immediate cessation of the haematuria and rapid improvement in the general health. Two months after the operation the patient seemed to be a normal child, and the urine had remained free from blood. The authors consider the case remarkable as being the first example on record of Henoch's purpura in which splenectomy was performed with success on the pathological findings, and also as being the first case of this disease in which phagocytic giant cells have been reported.

197. Acute Cholecystitis in a Child.

W. MÜLLER (*Zentralbl. f. Chir.*, December 4th, 1926, p. 3092), who records an illustrative case, mentions that diseases of the gall bladder in children are generally regarded as very rare. In 1914 von Khautz was able to collect fifteen cases, in a third of which the condition was recognized before the autopsy. In 1925 Gregov reported two personal cases and collected seventy-seven from the literature. As a general rule a distinction is made between cholecystitis with the formation of calculi and cholecystitis without such formation; the former is much the more frequent. Gregov states that acute non-calculous cholecystitis in children runs a more severe and violent course than the other variety, so that there is a greater risk of perforation, and a mistaken diagnosis such as appendicitis or intestinal obstruction is easily made. Müller's case was that of a boy, aged 4, who, fourteen days before admission, complained of pain in the right side of the abdomen. After temporary improvement he suffered from very severe pain in the same area and also in the right arm, vomited several times, and had complete intestinal obstruction. The abdomen was much distended. Under an anaesthetic a circumscribed swelling was felt two fingerbreadths to the right of the middle line of laparotomy; the inflamed gall bladder was found to be filled with pale green thin fluid and was excised. Bacteriological examination of the contents was negative, and subsequent recovery was uneventful.

198. A Chemical Substitute for Sympathectomy.

K. DOPPLER (*Med. Klinik*, December 17th, 1926, p. 1954) describes the treatment of a series of cases of Raynaud's disease, senile gangrene, necrosing amputation stumps, intermittent claudication, severe pains in the legs, and intractable non-varicose, non-syphilitic ulcers, due to defective circulation of blood in the lower limb. Attempts have been made to paralyse by cutting the sympathetic nerve supply to the femoral artery, and thus to secure permanent vaso-dilatation, but the results have not always been good. Doppler's method is to expose the femoral artery in Scarpa's triangle under local or general anaesthesia; the femoral sheath is opened and the vessel freely painted with a 7 per cent. solution in water of isophenol, or phenol, the latter being slightly more toxic. The artery, which is usually thickened, rigid, and almost pulseless, instantly begins to pulsate, and the limb, which has been blue or black, regains its colour. The wound is closed and Doppler states that relief is immediate; pain ceases, ulcers heal within a few days, and the good effects are permanent.

Therapeutics.

199. Serum Treatment of Bites of European Vipers.

P. MORITSCH (*Wien. klin. Woch.*, December 23rd, 1926, p. 1514) states that R. Kraus had previously shown that the serum obtained from the poison of *Lachesis jaraca* (*lanceolata*), a South American viper, proved efficacious in cases of bites by European vipers, and thinks that this discovery has a practical significance. The preparation of snake serum is a more difficult matter than the preparation of antitoxic serums against bacterial toxins, principally on account of the sensitiveness of horses to the snake poison, and especially on account of the large quantities of snake poison required for immunization. Antitoxic serums against the bites of the large snakes in tropical and subtropical countries can easily be produced if the necessary organization is present and the poison can be obtained from large snakes. It is much more difficult to prepare serum against the bites of small snakes, as only a small quantity of poison can be obtained from them. For this reason the serum treatment of snake bites in Europe has made little progress hitherto. As the result of his experiments Moritsch found that the serum obtained from the poison of *Lachesis jaraca* has not only the power to neutralize the poison of *Vipera aspis* (the French viper) in a mixture of serum and poison, but that this serum has the same neutralizing power when the serum and poison are injected separately. Subsequent experiments showed that the polyvalent serum made from a mixture of poisons of different South American vipers is able to neutralize a more than fatal dose of European viper poison.

200. Treatment of Urticaria.

G. MILIAN (*Paris Méd.*, January 15th, 1927, p. 81) recalls that the classical view of urticaria is that it is a toxic condition of either digestive or colloidoclasic origin, and asserts that most cases are due to infection. For many years he has noticed that infectious jaundice is often accompanied by urticaria, and that in patients previously free from this affection an attack often occurred in the course of some microbic disease. He has frequently seen urticaria developing in furunculosis and anthrax, the two commonest causes of this disease. Recurring attacks of urticaria have also been reported in cases of proved syphilis, these being rapidly cured by antisyphilitic treatment. In support of his contention, he reports two cases—one of abscess of the back, the other of a large furuncle on the arm—both associated with urticaria, and both proving to be staphylococcic infections. Milian has found that phosphoric acid is an effective antistaphylococcal agent, and in order to obtain a [illegible] nation of the phosphorus, instead of administering [illegible] s intravenously 20 to 30 c.cm. of galyl, which contains a considerable proportion of phosphoric acid. No other treatment, such as dieting, medicine, or protein desensitization, is employed. The author states that, combined with incision and evacuation of the pus, this method of treatment gives excellent results, both the primary infection and the accompanying urticaria being rapidly cured.

201. Garlic and Benzyl Benzoate in Arterial Hypertension.

C. MATTEI and J. DIAS-CAVARONI (*Bull. Soc. de Thér.*, December 8th, 1926, p. 267) studied the action of tincture of garlic and benzyl benzoate in arterial hypertension, with the following results. Tincture of garlic, in daily doses of 15 drops of a 1 in 10 solution morning and evening, appeared to have a very feeble and irregular action on the maximum blood pressure in cases of moderate hypertension. In the few cases where a favourable action was observed the fall of the systolic pressure never exceeded 2 cm. of mercury in extent or a few hours in duration, whereas increase of the dose and prolonged administration seemed to cause a fresh rise of the arterial pressure. The oculo-cardiac reflex usually remained unchanged, and the renal functions were not affected. Benzyl benzoate, in doses of 25 drops of a 1 in 20 solution morning and evening, appeared to have a very weak and transient effect in cases of moderate hypertension, since in two out of five cases the systolic pressure fell only 2 cm. and the diastolic only 1 cm. twenty minutes after ingestion of the drug, and did not keep down for more than forty-eight hours, although the treatment was continued for another six days. In three other patients a fall of only 1 cm. was obtained for forty-eight hours. Similar negative results were obtained by Musser of Philadelphia and other physicians, who gave benzyl benzoate to their patients for weeks without observing any effect on the blood pressure. In cases of considerable hypertension (with a systolic reading above 25 cm.) the effect of the drug in large doses (up to 100 drops a day) appeared to be more marked; the fall was as much as 5 cm. of mercury in six days, and persisted, the blood pressure not

reaching its usual level until three or six days after the end of treatment. The fall of the diastolic pressure, even in the most successful cases, was much less marked than that of the systolic. The oscillometric index, pulse, oculo-cardiac reflex, and renal elimination were not appreciably affected by benzyl benzoate.

Ophthalmology.

202. Blocking the Main Trunk of the Facial Nerve in Cataract Operations.

R. E. WRIGHT (*Arch. of Ophthalmol.*, November, 1926, p. 555) describes his method of producing complete circumorbital flaccidity in cataract operations. The only disadvantages appear to be that occasionally the paralysis lasts longer than is desirable and it may be necessary to perform tarsorrhaphy. He uses two parts of 4 per cent. novocain and one part of 1 in 1,000 adrenaline; 1 to 2 c.cm. of the mixture are injected. The lobe of the ear is pulled forward and the needle is inserted just behind the skin fold made by the drawn-up lobe, about the level of the tip of the mastoid process; the needle is pushed upward and inward and backwards along the anterior face of the mastoid and so towards the stylo-mastoid foramen.

203. Irradiation in Ophthalmology.

W. STOCK (*Med. Klinik*, November 26th, 1926, p. 1834) recommends the employment of *x*-ray treatment in certain diseases of the eye, but insists that it must only be given under strict medical control. He thinks that it is specially indicated before an operation of any kind, as, for instance, in carcinoma of the eyelids, tumours of the corneo-sclerotic junction, and pituitary and cerebral tumours. Tuberculosis of the iris in many cases clears up remarkably quickly under *x*-ray treatment, but the prognosis in cyclitis is much worse, and no success has hitherto been obtained in choroiditis. Scleritis, sclerosing keratitis, and tuberculosis of the conjunctiva and lacrymal sac are also suitable for *x*-ray treatment.

204. Retrobulbar Neuritis in Diabetes.

ACCORDING to L. M. FRANCIS and I. KOENIG (*Journ. Amer. Med. Assoc.*, October 23rd, 1926, p. 1373), apart from the commonly recognized ocular manifestations of diabetes, there are amblyopias affecting the peripheral and particularly the central visual fields. Retrobulbar neuritis arising in the course of diabetes is the evident result of an endogenous toxin which exercises a selective action on the papillomacular bundle of the optic nerve. Some thirty cases of this condition have been reported by Leber, Foster Moore, and others. Rönne has reported two cases, and described the process in the papillomacular bundle as being degenerative rather than a neuritis, and similar to that found in alcohol and tobacco amblyopias, except for the presence of granule cells in diabetes and not in tobacco and alcohol cases. The present authors report another case, and maintain that glycosuric amblyopia, involving the central visual fields, the result of an endogenous toxin, is a clinical entity; that the precise toxin or toxins cannot be specified, but the intimate relation between the presence of the ketone bodies, and especially acetone in the urine, coincident with the amblyopia, and their disappearance with the visual improvement and the disappearance of scotomas, suggest that the ketone bodies may be the index of the toxin or toxins themselves; that glycosuric amblyopia with central field changes is probably more common than is thought; and that routine central field studies should be made in all diabetic patients complaining of visual disturbances.

205. A Prism Test for Monocular Malingering.

E. H. SCHILD (*Amer. Journ. Ophthalmol.*, October, 1926, p. 741) describes a method of detecting visual malingerers. He uses a small piece of rectangular glass, one-half of which is a thick plane part which, near the middle line, tapers off to a prism of 5 degrees. With this glass the effect of either a plane or a double prism or a single 5-degree prism can be produced. This apparatus is an extension of the well known test for malingerers with a prism, but has the added advantage of being able to produce easily monocular diplopia, owing to the prism being incorporated with the plane glass, and then further to produce binocular diplopia by moving the glass so as to bring the prism part in front of the eye. The apparatus is held in front of the good eye. It has further use in determining what actual vision is on the test types of a suspected malingering eye. The lines of the test types must be shown separately, but, with this secured, it is possible to confuse the malingerer completely as to whether his diplopia is uniocular or binocular, and so assess the vision of the suspected eye.

Obstetrics and Gynaecology.

206. Chorion-epithelioma Malignum.

M. A. VAN BOUWDIJK BASTIAANSE (*Nederl. Tijdschr. v. Geneesk.*, December 18th, 1926, p. 2765), who records three illustrative cases, comes to the following conclusions: (1) Every abnormal haemorrhage following molar pregnancy is suggestive of chorion-epithelioma malignum. (2) Curetting in chorion-epithelioma malignum is not without danger, since there is great probability of its causing metastases, profuse haemorrhage, or perforation of the uterine wall. (3) The uterus should be removed at once without previous exploratory curetting, when the clinical diagnosis of chorion-epithelioma is probable; the older the woman the earlier should this be performed. (4) Laparotomy is advisable and the efferent vessels should be ligatured as far as possible at the beginning of the hysterectomy. (5) An operation is also indicated in the presence of a metastasis in the vagina. (6) After-treatment consists of combined radium and *x*-ray applications. (7) The transfusion of blood of women in the last months of pregnancy or in the puerperium should be considered.

207. Conservative Operation in Chronic Adnexal Disease.

O. P. MANSFELD (*Zentralbl. f. Gynäk.*, November 20th, 1926, p. 3040) states that total extirpation of the uterus and adnexa in chronic adnexal disease, while successful in 80 to 95 per cent. of cases, is followed in young subjects by such severe symptoms of the artificial menopause that Döderlein and others have abandoned it in favour of bilateral salpingectomy with ovarian conservation. The results of this operation, however, are much less satisfactory, with only 56 to 70 per cent. of lasting cures; and Heynemann, as well as Lindig, comparing severe menopausal symptoms following conservative and radical pelvic operations, have found that patients with ovaries but no uterus are in no more favourable position than those with neither. The inference is that the preservation, whenever possible, of uterus and ovaries in biological unity is desirable. This is attained by Beuttner's operation, described in 1918, in which a wedge-shaped portion of the fundus uteri is excised and the Fallopian tube or tubes removed by extending the transverse fundal incision to the mesosalpinx, the ovary being preserved, whenever possible, in whole or in part, and with intact vascular and nervous connexions, hemisection having been done if necessary. Mansfeld writes favourably of Beuttner's operation, which he has performed in 72 cases with 1.3 per cent. mortality. Its indications are: youth of the patient, adnexal disease on both sides, and apparent conservability of the ovary or ovaries. Among its advantages are a technical facilitation of approach to the adnexa and the possibility of removal of the portion of the fundus—usually diseased—lying between the two Fallopian tubes. Mansfeld's 72 patients included a majority of prostitutes, and 40 per cent. with pyosalpinx; he was able in 90 per cent. to preserve organic connexion between uterus and ovaries or ovarian remnants, and in 8 per cent. to effect transplantation into the sheath of the rectus abdominis, so that ovulation and menstruation were practically always preserved.

208. Pregnancy in Graves's Disease.

M. FABRE (*Bull. Soc. d'Obstét. et de Gynécol. de Paris*, November, 1926, p. 559) reports a case of Graves's disease presenting the symptoms of continued tachycardia with violent exacerbations, tremors, exophthalmos, and a small goitre. Radiotherapy being refused, haemato-ethyroïdin was administered in progressive doses. An amelioration of the condition followed this treatment, but unfortunately there was a relapse six months later caused by a domestic bereavement. The patient became pregnant in the next month and all treatment was stopped. In spite of this there was no return of the symptoms, and the mental and physical condition of the patient remained excellent. The pregnancy followed a normal course, and the patient was delivered of a healthy child, the puerperium being normal. The mother nursed the child, and her condition remains satisfactory. Fabre agrees with Fruhinsholz and Parisot that pregnancy has a beneficial, and sometimes a curative, effect on the Graves-Basedow syndrome.

209. Intentional Fracture of Foetal Humerus.

D. F. CLARK (*Surg., Gynecol. and Obstet.*, December, 1926, p. 795) considers that intentional fracture of the humerus is justified in exceptional cases when either the mother or child is in danger. Notes of five cases are given in which this procedure was adopted in breech extractions where it was found necessary to hasten delivery in the interests of the child, the arm being wedged by the aftercoming head. References to the literature and five years' hospital experience show that the occasions for such a measure are rare. Great care must be exercised to avoid injury to the brachial plexus or the soft

parts; the finger is hooked round the middle of the arm, preferably on its outer aspect, with rapid firm pressure until the bone is felt to yield. By such rapid fracture less brachial injury occurs than may result from prolonged pressure even when the arm is delivered unbroken, and this appears to be the case even with pressure at the inner aspect of the arm where the brachial plexus is open to more direct injury. In treatment such a degree of abduction with elbow flexion should be adopted as will favour proper alignment and such dorsiflexion of the wrist as will definitely overcorrect any tendency to wrist-drop. Clark advocates encasing the chest in a well padded plaster jacket from the waist to the axilla, and continued as part of the shoulder, arm, forearm, and hand plaster, the upper part of which latter should be removable in order to allow of the arm, forearm, and hand being frequently inspected. Should any tendency towards outward angulation arise it is important to correct this if necessary during the first ten days, while the callus is pliable. The method allows of successful breast feeding.

210. Syphilis of the Cervix.

G. GELLHORN (*Journ. Amer. Med. Assoc.*, November 27th, 1926, p. 1812) directs attention to syphilis of the cervix, which he believes is more common than is generally recognized and may be the cause of various forms of disability. The primary and secondary lesions are apt to be overlooked, since they produce no symptoms, but the tertiary lesions in the form of gummata cause bleeding and discharge and simulate carcinoma. Occasionally a syphilitic infection of the cervix may be very rapid and have a fatal termination. The diagnosis from malignant disease is based upon the relative scantiness of discharge from a syphilitic ulcer, the absence of pain and tenderness, the occurrence of lesions at some distance from the external os, and the characteristic sharp outline, yellow colour, and absence of inflammatory reaction of syphilitic ulcers. Dystocia may result from rigidity of the syphilitic cervix and malignancy may supervene. The author mentions three cases in his own practice in which syphilitic infection eventually became cancerous.

Pathology.

211. Effect of Calcium Ingestion on Serum Calcium.

IN studying calcium absorption from the intestinal tract W. BAUER and MARIAN W. ROPES (*Journ. Amer. Med. Assoc.*, December 4th, 1926, p. 1902) have tested the effect on the serum calcium of the oral administration of calcium, using the Clark modification of the Kramer-Tisdall method. Nine normal subjects, who had fasted for at least twelve hours, were given 5 grams of calcium lactate followed by 250 c.cm. of water. Calcium estimations were made every hour for the first six hours, and at the ninth and twelfth hours after ingestion. At the end of the sixth hour a light lunch containing from about 25 to 35 mg. of calcium was allowed. The readings gave a minimal elevation of 5 per cent., a maximal of 14 per cent., and an average of 8 per cent. in the serum calcium. The maximal rise came on between the first and fourth hours after ingestion, and was maintained usually for more than twelve hours. In a second experiment under similar conditions 10 grams of calcium lactate were administered to eight normal subjects. Here the minimal rise in the serum calcium was 5 per cent., the maximal 28.5 per cent., and the average 14 per cent., the maximal rise occurring between the first and fifth hours and lasting for twelve hours. These results disagree with those recently reported by Kahn and Roe, who obtained increases in the blood calcium as high as 103 per cent. after the ingestion of 5 grams of calcium lactate.

212. Immunization by the Buccal Route.

G. RAMON and E. GRASSET (*C. R. de la Soc. de Biologie*, December 10th, 1926, p. 1405) find that a large amount of tetanus toxin can be administered to rabbits by the mouth without giving rise to toxaemia; but if 2 to 3 c.cm. of ox bile are given just before the toxin, the animals die of generalized tetanus. At necropsy the epithelium of the stomach and intestine is found to be eroded or desquamated. The bile apparently injures the lining of the gut and thus renders it possible for the toxin to be absorbed. If instead of the toxin tetanus anatoxin is given after the preliminary administration of bile, immune bodies appear in the serum of the rabbit; eighteen days after injection they were able to neutralize two lethal doses of toxin for the guinea-pig. If the same amount of anatoxin is given subcutaneously the antibodies appear in far greater strength; after eighteen days 1 c.cm. of serum will neutralize 50 to 100 lethal doses for the guinea-pig. This work suggests that it is possible to induce a true humoral immunity in rabbits by the oral administration of tetanus anatoxin preceded by ox bile, but the degree of immunity reached is very much inferior to that obtained by subcutaneous administration of the same amount of anatoxin. E. Grasset (ibid., p. 1407) finds that a passive immunity may be conferred on rabbits by the oral administration of tetanus or diphtheria antitoxin after the usual dose of ox bile. Twenty-four hours after 9,000 antitoxic units had been given by the mouth 1 c.cm. of the rabbit's serum was able to neutralize 100 lethal doses for the guinea-pig; after the same dose subcutaneously the serum neutralized 1,000 to 10,000 lethal doses. G. Ramon and C. Zoeller (ibid., p. 1409) have repeated some of these experiments on human beings. They endeavoured to produce an active immunity to tetanus in two groups of persons by the oral administration of anatoxin, preceded in one group by pills of ox bile. No antitoxin could be detected in the serum of any of these persons. Similarly attempts with diphtheria anatoxin failed completely; they were also unable to confer passive immunity by giving purified tetanus antitoxin by the mouth. It is concluded, therefore, that while a low grade of active or passive immunity may be produced in rabbits by the oral method combined with administration of ox bile, it is quite impossible to do so in human beings.

213. Effect of Excessive Doses of Cod-liver Oil.

WHILE studying post-natal development, E. AGDUHR (*Acta Paediat.*, December 18th, 1926, p. 165) observed changes in the animals experimented with, which he attributed to the cod-liver oil given. In a series of experiments he found that large doses of oil caused a diminution in the number of erythrocytes with an increase of the haemoglobin value. At the beginning of the administration a leucocytosis appeared, followed by a leucopenia if the treatment were continued. The blood platelets were usually considerably increased in number, and several animals showed haemorrhages. The spleen was abundantly supplied with blood pigment, the suprarenals showed pigment atrophy, and the kidneys a nephrosis. Ulcerations of the gastric mucosa were common, accompanied by icterus. In the liver central necrosis and peripheral necroses in the lobuli were seen, as well as chronic passive congestion and acute yellow atrophy. The most pronounced changes in the heart consisted in pigmental atrophy and vacuolar degeneration of the muscle cells. Atelectasis and oedema were present in the lungs of many of the animals. Agduhr thinks that these poisonous effects are dependent on the composition of the basal diet, especially the content of vitamins B and C, and that they are less in warm weather and sunshine. In a subsequent paper on the changes in the heart through the presence of cod-liver oil in the food, A. HÖJER (ibid., p. 180) reports that in investigations on white rats he found that if large doses of oil were given as an addition to a complete diet, no cardiac changes were produced. If the diet was deficient in vitamin B, the oil caused severe atrophic changes in the heart, which were more pronounced if salts were also absent from the diet. Höjer holds that, if the diet is deficient in vitamin B, large doses of vitamin A may in a short time prove noxious to the heart, and he advances the hypothesis that a hypervitaminosis may be dangerous, but only in case of deficiency of the other vitamins or of other foodstuffs.

214. Estimation of Bilirubin in Capillary Blood.

FOR the estimation of the bilirubin content in blood D. DAVIS (*Amer. Journ. Med. Sci.*, December, 1926, p. 848) has devised a method whereby the test can be applied to small quantities. He uses glass tubing of 2 mm. bore cut into 10 cm. lengths. These are cleansed by immersion in 5 per cent. nitric acid, thoroughly washed in running water, and dried with alcohol and ether. Careful cleansing and drying is necessary to avoid haemolysis. Both ends of the tube are drawn out to capillary size. The patient's finger-tip is wiped dry and a few drops of blood obtained, the first drop being wiped off. Excessive squeezing should be avoided as this tends to produce haemolysis. A column of blood 2 cm. long is sufficient for accurate determinations. The blood is allowed to clot, the opposite clear end of the tube sealed off, and the tube centrifuged until a clear layer of serum is obtained. This is matched in diffused daylight against the standards; these, in tubes of the same bore, are made up of potassium bichromate, Meulengracht's original standard of 1 in 10,000 of this salt having been arbitrarily chosen to represent an "icterus index" of 1. Ten standards are recommended as a satisfactory set. Davis has found this test to be reliable and accurate if haemolysis is avoided and the determinations made within twenty-four hours after taking the blood. Owing to the small amount of blood required, this method is particularly useful in children. He adds that the blood should be taken in a fasting state, as food digestion and absorption causes a cloudiness of the serum due to food lipoids, and clear serum is essential. The other normal pigments of the blood occur in such very small amounts that the icterus index is not appreciably affected.

An Address
ON
HIGH BLOOD PRESSURE, ALBUMINURIA, AND GLYCOSURIA IN THEIR RELATION TO LIFE INSURANCE.

DELIVERED BEFORE THE JAMES MACKENZIE INSTITUTE FOR CLINICAL RESEARCH, ST. ANDREWS, [1]
BY
G. LOVELL GULLAND, C.M.G., M.D., F.R.C.P.ED.,
PROFESSOR OF MEDICINE AND CLINICAL MEDICINE IN THE UNIVERSITY OF EDINBURGH; PRINCIPAL MEDICAL OFFICER TO THE SCOTTISH WIDOWS FUND SOCIETY.

THE duties of a doctor in ordinary practice and in insurance work are entirely different. In the former case the patient pays the doctor to diagnose and treat his ailments, to support and comfort him; in the latter the insurance office pays the doctor to make certain scheduled inquiries and investigations into the case of a proposer who regards himself generally as a healthy man, and to express an opinion as to his present health and his prospects of living to a good old age. The doctor's only duty to the proposer is to treat him with courtesy and consideration; he must never tell him in what sense he proposes to report, because that report is the property of the insurance office. The medical examination forms of different companies differ slightly, but not in any important particular; they are nicely gauged to extract the maximum of information from the proposer and the maximum of diagnostic observation that can be expected from the doctor in general practice. Cases that are known, either before or after examination, to present special difficulty are brought, if possible, before someone in whom the office has special confidence.

HIGH BLOOD PRESSURE.

Judging from the syllabus of the Institute the scientific side of high pressure, and a good many of its practical bearings also, must already have been thrashed out.* I need not, therefore, dwell on theoretical considerations; my remarks will be severely practical.

In the medical examination papers of most life offices a question is now inserted asking that the blood pressure be taken in all proposers over 50 years of age, or where there is any reason to suspect that it may be abnormal. How is the pressure taken? I think we may assume that in ninety-nine cases out of a hundred it is taken with one of the aneroid sphygmomanometers. These are accurate instruments enough provided that they are checked from time to time by a mercurial instrument, and provided that the ordinary rules sent out with them are observed. One doctor recently reported that the pressure in a man of 35 was 150; he made no comment on this, and recommended the proposer as an average life. When he was asked to repeat the observation he wrote apologizing that he found his instrument when at rest was standing at 15 instead of at zero. Another experienced examiner gave the systolic pressure as 100, without remark. When asked to comment on the bearing of this figure on the eligibility of the proposer he replied that he had had his instrument calibrated since the examination, and it had been found to be out of order. The pressure was really normal. One has to remember that the practice of pressure estimation has been introduced comparatively recently, that many established practitioners have had to teach themselves to do it, and that too great accuracy must not be expected. Some men take a keen interest in pressure estimations, others approach them either with fear and trembling or with an unfounded confidence. Some go the length of reporting figures such as 170 or 180 without commenting on them, or apparently without regarding them as of any importance. Of course, a chief medical officer who has had some experience gets to know his examiners and what may be expected of them.

It is generally left to the examiner whether he uses the method of auscultation or palpation. Personally I practically always do both, but prefer auscultation as on the whole more correct. It is generally stated that the systolic figure from auscultation is higher than that from palpation, but I can often get readings exactly equal, and in a large proportion of cases the palpation figure is the higher. I am not yet able to determine why or in what groups of cases this difference occurs. In insurance work we have to depend on the maximum systolic figure. The diastolic is hardly ever given, and I do not think that our knowledge of the normal diastolic pressure and the meaning of its variations is as yet sufficiently great to allow us to make much use of the figure if it were given. The diastolic pressure can practically only be measured by auscultation—and I am pretty sure that palpation is more often used—and there is not yet a definite agreement whether the minimum diastolic is to be measured by the total cessation of all sound or by one of the changes in note which precede that. I find that these changes vary so much in different people that I regard cessation as the only safe reading. Unless the method used is stated in each case the reading is therefore valueless. The estimation of the pulse pressure looks as if it might be made to give indications of value in ordinary practice when a great deal more work has been done upon it. At present the wide pulse pressure of aortic incompetence and the narrow one of chronic interstitial nephritis are the only indications of much service.

What are we to regard as the normal blood pressure? I have looked up all the authoritative textbooks on the heart and vessels, and am amused to find with what unanimity a direct answer to this question is evaded—and wisely evaded. The truth is that it varies so much in different people, and in the same people at different times, that it can only be said that the normal limit ranges between 110 and 150, with the proviso that, other things being equal, young people tend to have a pressure nearer the lower figure, old people nearer the higher. The ordinary age rule holds only approximately. A child of 10 may have a pressure of 110, a man of 40 one of 140, but a man of 70 should not have a pressure of 170 if his heart and vessels are normal. A pressure of 120 is sometimes found in men of 60 or so, with normal hearts, soft arteries, and quite efficient circulations; but, on the other hand, if the pressure has been known to be higher at some previous time, a low pressure may be an early indication of cardiac failure. This will, however, generally be evidenced in some further way—by a rapid pulse, dyspnœa on exertion, or some alteration in the size or sounds of the heart. A writer, signing himself "Sphygmos," in the *Post Magazine*, December, 1922, makes a useful suggestion. He proposes that the rule should be:

Standard systolic pressure equals 120 *plus* half the age. Thus:

Age.	B.P.	Age.	B.P.
20	130	50	145
30	135	60	150
40	140	70	155

This suggested rule is a much closer approximation to the truth than the time-honoured addition of the age to 100, and is probably as near the actual facts as any rule can be.

I do not propose to catalogue the causes of high pressure; they are well known. I would only recall that, in addition to the organic causes, such as arterial and renal disease, obesity, worry, sleeplessness, and recent or prolonged physical or mental strain all tend to raise it, and must be inquired into by the examiner. But the commonest temporary difficulty is the excitement of examination. Offices generally require, for obvious reasons, that a proposer shall be examined by someone who is not his own doctor. An unbiased opinion is more easily got from a stranger and given by him, and there is the further advantage that in doubtful cases, or in proposals for large sums, a report from the private medical attendant can also be obtained, so that the proposer is seen from two angles. But examination by a stranger always increases a proposer's nervousness. I constantly find in patients that the pressure which I get is 10, 20, or even 30 mm. higher than those got by their own doctors. One can sometimes get this excitement-rise down by waiting and repeating the observation, but by no means always. I find pressures of 150 not

[1] Professor MacWilliam's address on "High blood pressure from the physiological aspect" was published a few weeks ago (January 22nd, p. 125).

uncommon in nervous young men whose hearts and arteries are quite normal. Anything above that figure I always regard with suspicion; for some reason, not always discoverable, that man is not quite normal, and it is not wise to accept him *at that time*. A repetition later, when the man is more at his ease with the examiner and the novelty of the procedure itself has worn off, may give a lower figure and the case may be accepted. But repetition may give information in the other direction. Recently a man was examined who was suffering from a cold, and whose pressure was just over 150. He was delayed for both these reasons, and it was found that the pressure had risen to 180, which made him ineligible. The wisdom of re-examination was brought out forcibly in another recent case, a proposal for a very large sum by a man of 60. The blood pressure was at first 164, it was known to have been 135 two years before, and the urine was normal. A later examination gave a blood pressure of 170, with a trace of albumin, and the case was declined.

Rejections for high pressure are apt to cause more than the usual amount of discontent among proposers and consequent worry to agents and officials. The proposers feel in perfect health, and it is of course often a matter of years before any symptoms arise. We all know people with pressures of, say, 200, who are leading active and useful lives, but naturally their tenure is precarious. Little is gained in insurance work by trying to distinguish between hyperpiesis and organic arterial change; in any case continuance of the former will certainly go on to the latter.

There is no room for doubt that people with high pressure are worse lives than those whose pressure is normal. Statistics are plentiful; a recent table published by May (BRITISH MEDICAL JOURNAL, 1925, ii, p. 1166), part of which I annex, is sufficiently convincing. It gives the experience of the Prudential office in 1920-24, and shows the ratio of actual deaths to expected deaths, the figure 100 being taken as the ratio.

1.	Systolic B.P. not recorded	97.1
2.	,, ,, under 140	102.8
3.	,, ,, 141-170	133.6
4.	,, ,, over 170	219.6
5.	,, ,, 200 and over	827.3

ALBUMINURIA.

It is a truism that albumin is present in the urine in many cases in which the kidneys are normal, and absent in many cases in which the kidneys are seriously affected. But just as a cardiac murmur is evidence that there is something wrong with either the heart or the man himself, so is albuminuria evidence that there is something wrong either with the kidneys, the urinary passages and their adnexa, or with the man generally. It is, in fact, the most valuable single indication of genito-urinary disturbance we have.

We must, of course, be sure that we really are dealing with albumin. The most reliable test, to my mind, is cold nitric acid, and if I am in doubt I supplement it by saturated solution of salicyl-sulphonic acid, a test which deserves to be used much more than it is. My reason for preferring nitric acid is that while it is a delicate, but not too delicate, test for albumin, valuable information is often obtained from the pigment rings and other deposits found, so that the very fallacies of the test are really an advantage, if you know how to use them. But many, probably most, practitioners use heat and acetic acid—a test not so delicate as the other but quite satisfactory provided they remember that boiling brings down a deposit of phosphates and carbonates, which is cleared up by the acid, and which is not albumin. We have a rule in the Scottish Widows Society that doubtful urines are to be sent to the head office if possible, and recently a urine was sent in with a note that the doctor could find nothing wrong with the case except the albuminuria. There was no albumin; the urine when boiled deposited phosphates, and he had either forgotten to add acetic acid or did not know that he ought to do so. It is not always appreciated that the acid added should be weak and just enough to acidify the urine. Strong acid or too much of it will convert a real precipitate of albumin to an acid albumin and render it soluble.

Let us now turn to the daily recurring difficulties. Many cases are fortunately simple enough. The man of 50 with albumin, a raised pressure, and an unsatisfactory heart is turned down at once. So is the youth with a recent history of scarlet fever, or the woman who had eclampsia two years ago, and still has albumin. Among the adult cases the most difficult are those in whom albumin is found—say, in a man of 40; the cardio-vascular system is declared to be quite normal, there is nothing in the history to suggest a kidney lesion, and no story of violent exercise just before examination. These cases have to be delayed and referred to their own doctors for investigation and report. If the examiner or the doctor would condescend to use the microscope occasionally, the explanation of many of these cases would probably be found at once in accidental additions—spermatozoa, oxalate crystals with red blood corpuscles, and so on. The most curious finding of that sort that I remember was the discovery of bilharzia on the day on which I examined a candidate, while it did not reappear, and there was no albumin in the urine of any of the seven following days. If casts other than hyaline casts, especially epithelial casts, are found, the case should be regarded as a kidney case and delayed until ample proof can be afforded that the kidneys are normal. It is misleading to say, as Maclean does, that "the presence of albuminuria with a few epithelial casts is no proof that we are dealing with defective kidneys," and to press the view that only renal efficiency tests give evidence of defective kidneys. As I shall point out later, they are often wildly misleading themselves, while the test tube and microscope give definite evidence that the person whom we are examining has a desquamative catarrh of the kidneys. This may be quite trifling or extremely serious, temporary or permanent, associated with grave deficiency of the kidneys or with practically none at all. The point is that albuminuria with epithelial casts means that the kidney is not normal at that moment, which is enough for the insurance examiner. I have not a doubt that slight degrees of nephritis are vastly more common, and more commonly recovered from entirely, than is believed; one proof of this was the complete recovery of such a large proportion of the cases of trench nephritis, and the fact that so few of them have slipped into chronic disease. An albuminuria of this sort is very much like an ordinary bronchitis—usually of no permanent importance, and clearing up completely; but it has to be remembered that an ordinary bronchitis is capable of killing the patient by bronchopneumonia, or, after repeated attacks, going on to chronic bronchitis, emphysema, and the rest. The association of ideas here reminds me how often albuminuria occurs with ordinary colds, either in the head or chest. This is obviously a toxic condition of the same kind as that occurring in the fevers. We have always found that it had disappeared on later examinations.

It is undeniable that albumin occurs with fair frequency in the presumably healthy. As far back as 1887 I took part in Grainger Stewart's investigations into this point; and, as you know, there was a collective investigation of 60,000 men during the war in the course of the research on trench nephritis. These statistics are absolutely valueless from the insurance point of view; indeed, the larger the numbers used the less valuable do they become, because it is impossible to find out the cause of the albuminuria in individual cases, or to follow them up. A study of ten or twenty cases from the time when albumin was first discovered till their deaths would be a piece of work of real importance.

But all the other albuminurias are cast into the shade by the problem of adolescent albuminuria. Probably these cases are in the proportion of 4 to 1 of all the other albuminurias put together, especially in offices which deal with large pension and superannuation schemes into which come large numbers of young clerks or teachers. The condition occurs most often in growing weedy youths in whom the circulatory apparatus, of which the kidneys form a part, is not yet "set"; but it is by no means confined to that class, and may occur in youths quite normal in every other way. The condition is also known to occur in girls, but they so seldom insure that no serious difficulty arises.

Our practice is to regard albuminuria in youths up to

'25 as probably functional unless there is something in the history or examination to suggest organic disease; to delay the case and refer the proposer to his own doctor for investigation; to lay stress on the presence or absence of albumin in the urine passed in the morning on rising, and, if it is consistently absent then, to regard the case as functional and take it without an extra. In some cases, where large sums of money were involved, we have asked for the performance in addition of the ordinary renal efficiency tests—urea concentration, blood urea, phenol-sulphone-phthalein excretion. All the cases investigated gave normal figures, as have others which I have investigated independently. I am inclined now to think that these tests are hardly worth the time and money expended on them in this particular class of case, because in mild nephritics of early age, which are the only kind of case comparable with the adolescents, these tests practically always give normal values also. To tell the truth, I am not greatly impressed by the value of any of these tests of renal efficiency. They generally merely confirm by an arithmetical figure the fact that kidneys are not efficient when we know already for other reasons that this is the case. Sometimes they actually tend to lead us astray. I saw the other day a lady whom I know to have chronic parenchymatous nephritis which has passed into the secondary contracted stage. She has a small amount of albumin, practically no casts, is anaemic, the heart dilated, systolic blood pressure 200, and so on, but is able to concentrate urea to the high figure of 4.2 per cent. I have often seen the same sort of difficulty with blood urea estimations, though perhaps they are a little more helpful. The point is, however, that in the mild symptomless cases, which alone are likely to come up for insurance examination, these tests will seldom help us and may sometimes mislead.

In adolescent albuminuria the quantity of albumin passed is of no importance. It is usually slight, but I have seen it large with no effect on the diagnosis or the ultimate result, which is that they always clear up. Towards the end of the war I saw a man in the forties whom I had known as a youth of 20 with albuminuria of very considerable amount, which persisted to my knowledge for three years. When I saw him in 1918 he was in charge of a munition factory and had been working practically day and night for three years, was a man of extraordinary vigour, had a perfectly normal heart and vessels, and perfectly normal urine.

Glycosuria.

Everyone knows how often glycosuria is discovered for the first time in the routine of insurance examination, and has followed up these cases until the condition was found to be unimportant or serious. I need say little about the true diabetic. His life has been made much more comfortable and useful by the better understanding of his diet and by the use of insulin, and in very many cases it has been prolonged. But his disease is not cured, and he is nearly as much at the mercy of septic complications, using the term in its widest sense, as he was before. He is not, and possibly never will be, a proper case for insurance. Can we take proposers suffering from the symptomless or nearly symptomless diabetes of elderly persons, the cases in which the hyperglycaemia and glycosuria depend, not on defective oxidation of glucose in the tissues as in true diabetes, but on defective storage in the liver? I think not. We all know that these cases often reach advanced age with glycosuria of many years' standing, but they are no more safe risks because of that than people with pressures of 200, who also often go on for many years. They may develop the more serious form of diabetes at any time, they are very apt to suffer from arterio-sclerosis, gangrene, eye lesions, neuritis, and they are bad subjects for operation and for intercurrent disease.

Fehling's solution is a quite satisfactory test for sugar, provided the two component solutions are kept in separate bottles, that equal parts of urine and the solution are used, and either heated together to boiling, or brought to boiling point separately and then mixed. The mixture should not be further heated after boiling. The clear olive-green discoloration which may occur with concentrated urines is disregarded, and only a definite precipitate is considered to be due to sugar—green, yellow, red, or intervening shades according to the amount present—and only if it occurs while the mixture is still hot. Almost any urine will precipitate if allowed to stand till it is cold. In doubtful cases there are always the yeast and phenylhydrazine tests to fall back upon.

If sugar is found to be present, it is customary to delay the case and refer the proposer to his own doctor for investigation and report. Of course, there may be other factors present, such as undue obesity, high blood pressure, loss of weight, etc., which may lead to the case being declined at once. The examiner should always inquire into the nature of preceding meals. The man who comes to examination after a tea of sweet cakes and four cups of tea each with four lumps of sugar, or after mixing champagne and port, is of course riding for a fall. The former case, which used to be called alimentary glycosuria, is probably generally an example either of mild renal glycosuria with a medium threshold or of rapid intestinal absorption of sugar, and a resulting "lag" curve of blood sugar; the latter is due to the toxic effect of the alcohol and other substances contained in the wines.

The after-history of the delayed cases depends on their own intelligence and that of their doctor, their social position, and whether they are really anxious to be insured or not. Some let the whole thing drop; some are willing to take any trouble to find out what is the real state of affairs; many take the middle course of going to their doctor at irregular intervals through the course of three or four months, so that we get a report on half a dozen examinations, in perhaps two of which sugar has been present, without any statement as to the length of time after a meal at which the specimen was taken, or the kind of meal which preceded it. The doctor is left much where he was before, except that probably he can be sure that the patient has not a true diabetes, though there is no guarantee that the findings may not represent a pre-diabetic state. If these cases are taken at all it is with misgiving and a heavy extra, in the hope, which is often fulfilled, that they will not be taken up. Sometimes we come across cases in which a man's own doctor reports a long series of negative examinations, which there is no reason to consider incorrect, but where the proposer passes sugar every time he comes to the society's examiner. Possibly in this case the glycosuria is due to suprarenal overactivity induced by excitement. I have never had an opportunity of examining one of these cases personally. The proper course in doubtful cases, if the circumstances permit it, is to have a full blood sugar curve taken. It is only in that way that renal glycosurias and "lag" curves can be distinguished and true diabetes excluded. We are told by some of the metabolic experts that renal glycosuria is of no importance, and that these cases ought to be taken at ordinary rates. I always put on an extra, and shall continue to do so. One reason for this is that I have seen cases of renal glycosuria pass into true diabetes. Another is that the differentiation of these cases is so recent an affair that the life-histories of very few cases have been completely studied, and we really do not know what becomes of them in the long run. The metabolic expert usually knows nothing about insurance, and while he is thinking of the present, or at most of the next few years, he forgets that the man of 25 with renal glycosuria ought still at the age of 65 to be paying his premium. How can he tell us what the carbohydrate metabolism will be after forty years? Incidentally it is pretty certain that the passage of sugar irritates the kidney at last. The same conclusions probably apply to the "lag" curves, the knowledge of which is even more recent than that of renal glycosuria.

Occasionally we come across cases of glycosuria which are very difficult to understand or explain. A few months ago I had a lady under observation for some time who told me that eighteen months before she had been in a nursing home in London under one of the best known diabetic experts there for the treatment of diabetes, and was discharged on a diet on which she was told she would remain sugar-free without insulin. The blood sugar curve taken at that time was certainly a mild diabetic one. She tired of the diet after a time, went back to ordinary things, and when

I saw her was sugar-free; nor, though I encouraged her for other reasons, as she was miserably thin, to take large quantities of starches and sugar, did she ever show sugar in the urine, while her blood sugar curve was perfectly normal. Another recent case was that of a man who at intervals of a few months passed large quantities of sugar for a few days at a time without making any change in his habits, and with no discomfort except the polyuria.

I might multiply these out-of-the-way cases indefinitely from my experience and probably from yours. Many of them occurred before blood sugar curves were dreamt of. They are of little general interest, but they serve to prove that we do not yet know all there is to be known about the production of glycosuria, and that until we do know a good deal more it behoves us to be cautious, especially in insurance work.

A Lecture ON MULE-SPINNERS' CANCER:

CLINICAL FEATURES AND TREATMENT.*

BY

A. H. SOUTHAM, M.A., M.D., M.CH.OXON., F.R.C.S.ENG.,

HONORARY ASSISTANT SURGEON, SALFORD ROYAL HOSPITAL; ASSISTANT SURGICAL OFFICER, MANCHESTER ROYAL INFIRMARY; ASSISTANT SURGEON, ROYAL MANCHESTER CHILDREN'S HOSPITAL.

IT is only within a very recent period that cancer of the scrotum and skin has come to be recognized as being associated with the occupation of mule-spinning in cotton mills. The subject was brought into prominence by an article on cancer of the scrotum published in the BRITISH MEDICAL JOURNAL in 1922.[1] Since that date numerous cases have been reported to the Factory Department, and through these notifications, through the mortality records of the Registrar-General, and from other sources the department has been able up to the present to trace 667 cases—570 in spinners and 97 in ex-spinners who passed into other employment.

Following the publication of the above-mentioned paper the Federation of Master Cotton Spinners and the Association of Operative Cotton Spinners and Twiners, with the co-operation of the Factory Department, drew up a warning leaflet in 1923. This was distributed among the workers to direct the attention of the industry to the prevalence of the disease. The importance of cleanliness was urged, and the danger of delay in securing early medical treatment, as soon as symptoms show themselves, was emphasized.

On March 27th, 1925, the Home Secretary appointed a Departmental Committee to inquire into the question; its report was published in February, 1926. In the opinion of the committee the evidence was strongly in favour of the view that this form of cancer was due to the prolonged action of mineral oils.

As the occurrence of the disease has only been recognized for a few years the premonitory signs and clinical course of the condition have not yet been fully studied. It is proposed to describe shortly the clinical features of this form of cancer as it occurs amongst mule-spinners, and to show how the disease can be diagnosed at an early stage after its commencement. At the onset it is a relatively benign type of malignant growth, and early operation for its removal offers a good chance of cure.

The lesion on the scrotum is a cutaneous epithelioma similar to that arising elsewhere. It is commonly seen in men between 40 and 60 years of age, though it may occur earlier, or at an age considerably older. The first manifestation is a wart-like excrescence or a flat plaque due to local hyperplasia of the epithelium. This wart or papule is usually single and about the size of a pea; it is raised above the surface and may be covered with scales, which the man removes by scratching, leaving a small bleeding surface over which the scales soon re-form. The only symptom which troubles the patient at this stage may be itching about the growth. In other cases there may have been several small papillomata present on the scrotum, and one of these takes on the above characteristics whilst the others remain benign. Later the growth sloughs and definite ulceration follows in six to twelve months, when the patient seeks medical advice on account of the irritation and discharge.

Until quite recently it was uncommon to see cases in the early stages, for three reasons. First, for reasons of modesty, owing to the position of the growth; secondly, because the men did not pay any attention to these slight symptoms; and thirdly, because both the spinners and their doctors failed to recognize their significance and to realize the importance of early treatment. Owing to the wide publicity given to the disease in the last four years the men themselves are now beginning to understand the meaning of the initial signs and to seek medical advice if symptoms appear.

When fully developed the tumour is proliferative, of the cauliflower type, with a raised everted and indurated edge surrounding an ulcer. The ulcer is often the size of a shilling; it is of relatively slow growth and rarely involves the deeper structures. This is due to the fact that the lymphatics of the scrotum and testis are quite separate and there is no anastomosis between the superficial and deep systems.

It may sometimes be difficult to determine when the lesion has become malignant, but from the very first it should always be regarded with grave suspicion. The disease is usually seen on the scrotum and on the left side; in approximately 25 per cent. of cases the growth may be found on other sites, chiefly the head, neck, and forearm.

The tendency for this type of cancer to form metastases is at first slow and its malignancy is not great. In the initial stages the enlarged inguinal glands do not necessarily contain carcinomatous deposits; the enlargement may be purely inflammatory, due to the infective processes taking place on the surface of the ulcer. Sooner or later, however, malignant invasion of the glands is bound to occur, and with the progress of the disease the most conspicuous feature is the breaking down of the glands in the groin. Finally death follows from exhaustion due to septic absorption or haemorrhage from the femoral vessels, whilst occasionally internal metastases in the abdominal glands, liver, or peritoneum give rise to abdominal symptoms or pain from pressure on nerves.

It is important to remember that the disease at first and for a considerable time is purely local, and there is ample time both for diagnosis and treatment before it has spread to other parts.

TREATMENT.

Cancer of the scrotum should be one of the most favourable types of malignant disease for surgical treatment, as it can be discovered at a very early stage. The cure of the disease depends on its early diagnosis and radical removal.

In considering treatment, it is essential to have a clear understanding of the lymphatic vessels of the scrotum and the glandular areas into which they drain.[2] The superficial lymphatic system consists of a fine network of lymph capillaries covering the whole scrotum, lying beneath the skin and external to the dartos muscle. There is a free anastomosis of this network across the two sides of the scrotum. The collecting channels from this run above and below Poupart's ligament to reach the superficial inguinal glands. The trunks coming from the anterior surface of the scrotum may pass direct to a gland which lies just internal to the anterior superior spine of the ilium, and is the most external gland of the horizontal set. This point is of considerable importance, since mule-spinners' cancer is commonly found on the anterior aspect of the scrotum. The lymph channels run both superficial and deep to the saphenous vein. No channels appear to pass the inguinal glands to reach the iliac glands direct, and primary lymphatic infection is therefore only found in the inguinal glands.

The treatment of this disease is essentially surgical. Any other form of treatment can be merely palliative. All forms of radiotherapy have proved disappointing and appear to be of doubtful value. We know of no case improved after *x*-ray treatment, in spite of the fact that

*Delivered in the Post-Graduate Course of the Manchester Committee on Cancer.

these tumours are so superficial and easily reached. In the early stages all scrotal warts and papillomata seen in mule-spinners should be removed, and local excision should be followed by microscopical examination.

When a definite ulcer is present a wide operation, consisting of removal of the growth with a healthy margin of skin and excision of the lymph-bearing areas in both groins, should be carried out. In the past many cases were treated by simple removal of the scrotal growth without excising the glands. Metastasis in the groin occurred later on in the majority of these cases and further operation was then often impossible.

It is important to treat this disease radically at the onset by removing both growth and glands at once. Our knowledge of the lymphatic system shows that it is only necessary to remove the scrotal ulcer and skin around it; deeper dissection is not required if the whole thickness of skin and dartos be excised. The glandular areas require more extensive dissection, and owing to the free anastomosis between the superficial lymphatics of both sides of the scrotum, bilateral infection of the glands is not uncommon. This is particularly likely to occur when the growth is situated on the anterior aspect of the scrotum.

The incision for the glands should extend from the spine of the pubes right out to the anterior superior spine of the ilium with a convexity downwards. The whole mass, consisting of fat, glands, and lymphatic vessels, is dissected out from above downwards in one piece, the dissection extending above Poupart's ligament. The upper three or four inches of the saphenous vein are removed also. All the glands and fatty tissue in Scarpa's triangle are thus excised and the femoral vessels stripped clean. These wounds are closed without drainage, and if the glands have not broken down should heal without any difficulty. There may for a short time be an escape of lymph from these incisions, owing to the division of the lymphatic channels, but this soon ceases. Oedema of the lower limbs after operation, due to the same cause, is sometimes troublesome, but, in the absence of infection, clears up in a few months.

Prophylactic application of x rays has been given as a routine after operation for about twelve months.

PROGNOSIS.

The prognosis after surgical treatment in mule-spinners' cancer is generally considered to be good, as in other types of skin epitheliomata.

In an investigation of the after-results following operative and x-ray treatment, Dr. John Bromley, of the x-ray department of the Manchester Royal Infirmary, has collected details relative to thirteen cases dealt with during the past two years, which he has kindly placed at my disposal.

After-Results of Operative and X-Ray Treatment of Thirteen Cases of Mule-Spinners' Cancer.

Alive and well	4=31	per cent.
Have had recurrence	6=46	,,
Dead	3=23	,,

Such figures as these, although few in number, show conclusively the serious nature of this condition.

The cases under investigation have proved beyond doubt that deep x-ray therapy has been of little or no value as a prophylactic agent against glandular recurrence, and was of even less value in preventing local recurrence of the disease. In view of the fact that ordinary types of skin epitheliomata appear to give satisfactory results with both radium and superficial x-ray therapy, a series of cases of mule-spinners' cancer are now being treated with this type of radiation to see if the effects are better than those obtained after deep therapy. The best results were unquestionably obtained in those cases in which both the growth and the glands had been removed by the surgeon.

Finally, in considering the etiology of this disease, it appears likely that certain individuals possess a peculiar susceptibility to the irritant effects of mineral oil. Whilst this only affects a small minority of spinners—statistics showing that of the 25,000 adult males engaged in mule-spinning approximately 2.5 per 1,000 develop the disease—the problem presented merits consideration.

An important question arises as to whether a spinner who has once suffered from this form of cancer should be advised to return to his occupation in the mill on recovery. Apparently it can only be answered by examination of a series of statistics, and is at present engaging our attention. It should be made a rule that all patients shall attend for inspection, after operation, at regular intervals. In this way any recurrence of the cancer will be discovered at an early stage and curative operation will be carried out with a good chance of success.

THE CLINICAL ASPECTS OF ACUTE PANCREATITIS.*

BY

HAMILTON BAILEY, F.R.C.S.ENG.,

GILLSON SCHOLAR, SOCIETY OF APOTHECARIES; SURGEON, DUDLEY ROAD HOSPITAL, BIRMINGHAM.

ACUTE pancreatitis, the most serious intra-abdominal inflammatory catastrophe, was first recognized by Dr. Fitz of Boston,[1] who communicated his observations to the New York Pathological Society in 1889. Since then other observers have added their quota, and to-day we are able to diagnose this disease in its typical forms, and to confirm the diagnosis scientifically.

FIG. 1.—Section of pancreas from a patient who died eight days after operation for acute pancreatitis. The pancreatic tissue is invaded by bacteria. A culture from the gall bladder at the time of the operation grew *Staphylococcus aureus* in profusion. (Author's case.)

The salient features by which the disease can be distinguished from other acute abdominal disasters are as follows: (1) The patient is usually fat; it would appear that obesity definitely predisposes to this disease. (2) There is a considerable accumulation of evidence to show that pancreatitis is recurrent—that is to say, that the same patient is the victim of several visitations of the disease. Dick[2] reports the case of a publican, aged 44, who had an attack of acute pancreatitis; it was treated expectantly, and he recovered. Two months later the patient returned with a second attack, and died twenty-four hours later. Timbrell Fisher[3] describes the case of a man who had two attacks, separated by an interval of ten months. On each occasion the pancreas was drained and the man recovered.

A case under my own observation, in which I collected the past history, illustrates the recurrent nature of this disease.

The patient was a brewer's drayman. In 1907, at the age of 36, he was suddenly seized with acute abdominal pain. He recovered sufficiently to attend the medical out-patient department of the

* A paper read before the Birmingham Division of the British Medical Association.

London Hospital. A diagnosis of acute alcoholic gastritis was made. He was given medicine, and discharged a few weeks later as cured.

In 1910, after drinking a glass of water (apparently by mistake), he was suddenly seized with severe pains similar to the last. He vomited several times, and was admitted to the hospital. On examination tenderness was present over the gall bladder area. The symptoms abated, and he was discharged.

In February, 1924, he had a third severe attack while rolling barrels. Pain was so acute that the patient collapsed. The brewery at which he worked was immediately opposite the hospital, and I saw him within an hour of the onset. The patient was profoundly shocked, cyanosis was present, and abdominal rigidity entirely absent. A diagnosis of acute pancreatitis was made. After antishock treatment had been instituted the abdomen was opened. Fat necrosis was general; the pancreas was purple and oedematous; the gall bladder was distended, but no stones were present. Cholecystotomy was performed, and the lesser sac drained. The patient recovered and returned to work.

In July, 1924, he was seized with a fourth attack. He was admitted cyanosed and quite pulseless, although conscious. He stated that it was exactly the same pain, and it began in the middle of the night forty-eight hours before. He did not respond to antishock treatment, and died three hours later. The necropsy revealed advanced haemorrhagic pancreatitis.

This case is both instructive and suggestive. In the first place it admirably shows the recurrent nature of the disease, and secondly, it makes one wonder if many of the sudden but indefinite attacks of abdominal pain which pass off under expectant treatment are not pancreatic in origin.

Rigidity.

An outstanding feature, which helps to differentiate pancreatitis from other acute intra-abdominal inflammations, is the almost complete absence of rigidity of the abdominal wall. This point has received scant attention, but is emphasized by Timbrell Fisher, who states: "Rigidity is not characteristic, and may be completely absent."

Of the seven cases in which I have palpated the abdominal wall of patients suffering from acute pancreatitis abdominal rigidity has been completely absent in six instances. This comparative flaccidity is accounted for by the fact that pre-operative general peritonitis is absent. Mr. Huddy, as a result of his pathological work, has made it quite clear that the absence of general peritonitis is a remarkable feature in this disease.

Cyanosis.

Cyanosis is a fairly common accompaniment of the most acute forms of this disease; it is most marked in the cervico-facial region. The general explanation given to account for this phenomenon is that the abdominal musculature and diaphragm are held so rigidly that the respiratory movement is embarrassed and anoxaemia results. Such a hypothesis is untenable, for the abdominal muscles, far from being held in vice-like contracture, are relaxed. The cyanosis is undoubtedly due to the profundity of the toxaemia. Ogilvie has come to the conclusion that this toxaemia is due to the absorption of protein metabolites, particularly histamine, formed from the auto-digestion of the tissues, by the liberated pancreatic ferments. This is a rational explanation. Profound toxaemia will often give rise to cyanosis, as those who witnessed cases of heliotrope cyanosis in the 1918 influenza epidemic will testify. Experience teaches us that in a toxaemia the deeper the cyanosis the more surely can we hear the beating of the wings of the angel of death. Acute pancreatitis is no exception.

The Pain.

A late chief, under whom it was my privilege to work, said: "When I get a telephone call, and hear that it is an acute abdomen, and the doctor says that he has given morphine and the pain is unrelieved, I say, 'Ha, acute pancreatitis!'"

The widespread belief that the pain in acute pancreatitis is more severe than that of other abdominal catastrophes seems to have originated in a remark uttered by John B. Murphy,[4] who in the surgical clinics of Chicago is reported to have said: "The pain of acute pancreatitis is enormously greater than that of perforated duodenal or gastric ulcer."

We have no scientific gauge with which to measure pain. But while admitting of exceptions I am inclined to agree with the observations of Ogilvie[5] at Guy's Hospital, who says: "It is very doubtful if the onset is as sudden or the pain as agonizing as it is in cases of perforation. . . . Cases of perforation never move from the place where the pain has felled them." All observers agree that the pain is epigastric, and passes to the back. This radiation to the back is of considerable differential significance.

Loewi's Mydriatic Test.

In the mydriatic test we have a valuable scientific confirmatory sign which, above all, is eminently practical. It requires no laboratory—an important point when dealing with a grave emergency. I have heard several surgeons speak disparagingly of the sign, but, as a rule, one finds they have not given it a fair trial.

In order to get reliable results the technique laid down by the discoverer, Otto Loewi of Vienna, must be carried out. The pupils are examined; into one conjunctival sac four drops of fresh 1 in 1,000 adrenaline solution are instilled; after five minutes four more drops are instilled, and the pupils examined again after half an hour. While adrenaline has no effect upon the pupil of a healthy individual, in acute pancreatitis a positive reaction—namely, *dilatation of the pupil—is quite often obtained.* (Fig. 2.)

FIG. 2.—Loewi's test, a positive reaction. Photograph taken twenty hours after an operation for acute pancreatitis.

The dilatation is not infrequently slightly eccentric, and often conspicuously oval in form.[6] A negative pupillary reaction implies nothing, but a positive result in an acute abdominal case is highly suggestive of acute pancreatitis. The true explanation of this remarkable phenomenon is unknown, but it may be suggested that the inflamed and swollen pancreas irritates the solar plexus; the whole of the autonomic nervous system is thus rendered very sensitive, and the adrenaline detonates the ocular sympathetic.

The foregoing are the outstanding clinical features of acute pancreatitis from a differential standpoint.

Some points may also be mentioned which may be categorized as of minor importance, not because they lack interest, but because either they are rarely present or they lack the possibility of immediate application.

1. *The presence of a palpable abdominal tumour* is rarely noted; probably obesity militates against the regular detection of a pancreatic enlargement.

2. *Grey Turner's sign*[7] is a local discoloration of the skin. It usually occurs in the loin. The patches have the appearance of the skin in late extravasation. It is only seen in cases of some two or three days' standing. The condition is clearly due to the direct action of the pancreatic juice, which escapes by way of the retroperitoneal tissues and passes by the most direct route to the surface.

3. *The diastatic index of the urine* is not uncommonly raised from the normal 15 units to 150 or more. Recently I had a case in Dudley Road Hospital in which the index stood at 200 units. This test would be most valuable if it could be performed readily at the bedside. Unfortunately, by the time the report has come from the laboratory the index has ceased to be anything but a matter of academic interest. Sir Gilbert Barling[8] has shown that this test is not uniformly reliable—the increased index may be present in pneumococcal peritonitis.

4. *The Lipase Index of the Urine.*—Gordon Cameron, in 1923,[9] described a test for lipase in the urine. This again is essentially a laboratory procedure.

5. *Sugar in the urine* is present in a small proportion of cases of acute pancreatitis. It is of little diagnostic significance unless we know that glycosuria was not present previously.

TREATMENT.

Certain principles of treatment are agreed upon, but there are differences of opinion as to some details. Of the necessity for operation Deaver[10] says: "Instant drainage of the pancreas is the procedure indicated. Recovery from acute pancreatitis is not unknown, but it is safe to say that cases which recover by medical, that is expectant, treatment, would also recover by operative treatment, while some of those who die without operation might have been saved had they been submitted to operation."

Laparotomy being imperative, the patient should be given antishock treatment whilst preparation is being made for operation, and during the interval the result of the mydriatic test may be observed.

A liberal supply of oxygen should be administered with the anaesthetic from the commencement. I favour the mid-line incision because of the rapidity with which the abdomen can be opened and closed. The diagnosis is at once clinched by the blood-stained exudate and fat necroses. The pancreas is most readily explored by tearing the layers of peritoneum between the stomach and the transverse colon. In rare cases *where there is marked ptosis* of the stomach the pancreas can be conveniently exposed through the gastro-hepatic omentum. It is never justifiable to approach the organ through the transverse mesocolon, for subsequent drainage is difficult, and infection of the general peritoneal cavity almost certain. (Fig. 3.) Sir Berkeley Moynihan[11] has

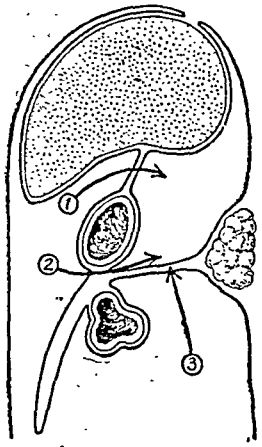

FIG. 3.—Diagram of routes of approach to the pancreas. (1) Through the gastro-hepatic omentum. (2) Through the gastro-colic omentum. (3) Through the transverse mesocolon.

emphasized the importance of packing off the field of operation thoroughly, in order to avoid soiling the general peritoneal cavity with the infected contents of the lesser sac.

Various Operative Procedures Recommended.

Incision of the pancreas was introduced by von Mikulicz in 1903.[12] The general consensus of opinion to-day is that this procedure involves a very grave mortality. Sir Berkeley Moynihan has modified the method, and recommends that the peritoneum covering the pancreas should alone be incised; but in my limited experience, with everything in an inflamed and turgescent state, this is very difficult to carry out.

Posterior drainage was championed by Barker[13] of University College Hospital. When the diagnosis was confirmed by laparotomy he made an incision below the right twelfth rib, and, with one finger in this incision, he burrowed his way through the extraperitoneal fat to the head of the pancreas, guided by the other hand in the abdomen. This would appear to be the best method in those cases which tend to go on to abscess formation, and in which the inflammatory process is mainly retroperitoneal.

Gall stones are present in about 50 per cent. of cases submitted to operation. Cholecystitis is probably intimately associated with pancreatitis, and consequently, if the condition of the patient permits, the diseased gall bladder should receive attention.

Cholecystotomy and Cholecystectomy.—Cholecystotomy is a very simple rapid procedure. It is very doubtful if it is of much value in draining the common duct. Nevertheless, there is much to be said in its favour as a supplementary therapeutic measure in acute pancreatitis. Following Deaver's teaching of the lymphatic origin of pancreatitis, I believed that, in those cases in which the gall bladder was definitely diseased, cholecystectomy, in addition to local treatment, would, if the patient survived the existing attack, bring about a permanent cure. Doubt has now been cast upon this belief; I have recently had a case of a mild recurrent attack in a patient in whom I had four months before extirpated the gall bladder and drained the lesser sac. The attack, however, passed off. Further proof that cholecystectomy is not a panacea is afforded by Holden and Moran,[14] who cite a case of acute pancreatitis occurring seven years after the gall bladder had been removed for uncomplicated gall stones. Therefore, in a grave emergency, cholecystotomy, on account of its simplicity, should have priority.

Archibald's Operation.—Archibald of Montreal,[15] as the result of much experimental work, has come to the conclusion *that acute pancreatitis is largely due to a spasm* of Oddi's sphincter, which surrounds the ampulla of Vater. This sphincter will resist an intraduodenal pressure of 1,000 mg. of water. His operation consists of opening the duodenum and dividing the sphincter. This procedure is still young, but has been received with enthusiasm in the new world.

Appendicostomy.—Appendicostomy has recently been recommended for the rapid instillation of large quantities of saline to collapsed patients after abdominal operations. Billington and Goodwin (1912)[16] advocated this procedure, and applied it successfully in two cases of acute pancreatitis.

Post-operative Treatment.

The escaping pancreatic juices tend to digest the abdominal wall and sutures contained therein. "Burst abdomen" is not an uncommon complication, and should be especially guarded against by suitably supporting the incision. Digestion of the skin around the wound may be effectively prevented by smearing the skin with an ointment containing 2 per cent. of hydrochloric acid, which renders the ferments impotent.

Pancreatic Asthenia.—Whipple[17] has drawn attention to a most interesting condition which he has named pancreatic asthenia. It occurs during the second and ninth days after operations upon the pancreas, and lasts for a varying period; seven of his forty cases followed operations for acute pancreatitis. Weakness is the chief complaint; the asthenia in some cases approaches that of Addison's disease; there is a mask-like expression, a drawling voice, muscular relaxation, and a tendency to salivation. The only treatment of permanent value is blood transfusion. It is curious to note that the request for bizarre dishes is often the first indication of a subjective improvement.

Conclusion.

The mortality of pancreatitis is still very high. Doubtless some improvement can be brought about by earlier diagnosis; but no substantial advance is likely to be made until the cause has been conclusively elucidated.

The riddle of all acute intra-abdominal inflammatory catastrophes will probably be solved when the key to the commonest is found—I refer to acute appendicitis.

ARREST OF HAEMORRHAGE AFTER PROSTATECTOMY:
A HAEMOSTATIC CLAMP.

BY

R. OGIER WARD, M.CH.OXON., F.R.C.S.ENG.,

ASSISTANT SURGEON TO ST. PETER'S HOSPITAL; SURGEON-IN-CHARGE OF THE GENITO-URINARY DEPARTMENT, THE MILLER GENERAL HOSPITAL.

THE surgeon who can perform an operation with the least damage to the tissues, with the least loss of blood, and with least sepsis gives his patient the best chances of successful recovery. The operation of prostatectomy, in whatever way it is conducted, leaves much to be desired in respect of each of these three ideals.

Access to the prostate by the suprapubic route always involves some disturbance of part of the peritoneum; from this and from the drainage of the bladder a local peritonitis results; usually this is unimportant, but sometimes it is severe enough to be a factor in the development of troublesome meteorism. Again, the incision through the abdominal wall has the effect of impairing temporarily the function of the recti abdominis. This is of consequence because, as accessory muscles of respiration, they have a part to play if the diaphragm is to function fully. Admittedly, approach to the prostate through the perineum spares the patient injury to these two important structures, but there are other disadvantages to this method of prostatectomy which cause it to be less often employed. Damage to tissues necessarily accompanies the removal of the prostate by enucleation, for however skilfully it is carried out, and whether the gland is reached from above or from below, this is essentially a forceful manœuvre and therefore shock is often produced.

In prostatectomy sepsis is inevitable, primary union is impossible, and healing can only be by granulation; and the sepsis accompanying this often places a severe tax upon the patient's powers of recuperation. If, then, there are means by which the third ideal can be reached—namely, the avoidance of loss of blood—it is certainly desirable to adopt them, and most surgeons endeavour to effect this in some way or other. To be sure there are some who declare that it does old men good to bleed, but it seems unlikely that those who hold this view will object to the arrest of haemorrhage from their own prostatic cavities, if ever these have to be emptied of an adenomatous enlargement. It is true that patients do not often die of haemorrhage after prostatectomy, though it is equally true that this not uncommonly gives cause for much anxiety. But it is obvious that the patient who has to recover from shock, and has subsequently to withstand sepsis, will do so with difficulty if he has lost much blood; and it is certain that when sepsis, renal failure, cardiac failure, and bronchopneumonia kill patients after prostatectomy this is often because their vitality has been seriously impaired by haemorrhage.

In prostatectomy there is trivial bleeding when the abdomen is opened, and there is often more when the bladder is incised, but though this may be considerable the vessels are easily ligatured. It occurs most while the prostate is being enucleated, and though this cannot be prevented, yet it should be noted that it may be unnecessarily large if the surgeon takes a long time to remove the growth, and does not do so skilfully. During the formation of granulations some bleeding continues, and the urine is commonly tinged for the first few days after the operation. But the most serious haemorrhage, after the completion of the operation, is that which occurs during the subsequent five or six hours. This is almost always considerable, and it is not possible to predict with any certainty that it may not be quite serious.

There are various methods of controlling the haemorrhage. Freyer used to flush the prostatic cavity with lotions at 120° F. In the open operation of Thomson-Walker the suture of the periphery of the inlet to the prostatic cavity does much to stop bleeding, for this occurs chiefly from beneath the torn vesical mucous membrane. Sometimes, in spite of this procedure, packing is necessary, and this is because in these cases there is haemorrhage, often arterial, from the lateral walls of the prostatic cavity; the bleeding points can sometimes be identified, but to secure them by transfixion and ligature is occasionally impossible, and in any case involves a further prolongation of the operation.

The prostatic cavity can be packed with ribbon gauze, and if this is properly done haemostasis is secured, though this is not quite so easily obtained as might be expected, the reason being that it is difficult to bring pressure to bear upon the circle of torn vesical mucous membrane from beneath which, as has been said, most of the bleeding occurs.

If the packing is left in for forty-eight hours its condition on removal shows the state of sepsis which has arisen round about it, whereas if it is taken out after twenty-four hours, and indeed at whatever time it is removed, there is some risk of again starting enough bleeding to be of consequence—for the process of withdrawing the gauze involves always a disturbance of the tissues forming the prostatic cavity and especially the mucous membrane at the prostatic inlet. The removal of the packing is also a cause of pain, and this is often bad enough to necessitate the employment of nitrous oxide anaesthesia.

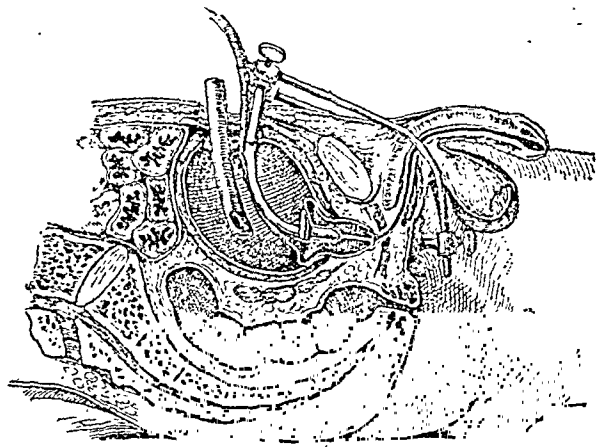

FIG. 1.—The haemostatic clamp and bag in position after removal of the enlarged prostate.

To overcome the disadvantages inherent to the use of packing Hagner devised a haemostatic rubber bag which was placed in the prostatic cavity and then distended. Pilcher has improved upon this, and uses a bag which is held in position by a tube, which traverses the urethra, tension upon this being maintained by strapping it to the thigh. With the same object, Hamer has devised a metal frame based upon the pubic arch, to which the tube is attached; and more recently Millar has suggested a method of weight extension. I employ a different method, which is designed to do away with any need for traction upon the bag, by providing a fixed support above and counter-pressure below. Occasionally incontinence of urine has followed the use of the Pilcher bag, and it is due to the compressor urethrae becoming stretched because the apex of the bag has been drawn into the membranous urethra. To avoid this, V. A. Hunt arranged for a traction upon the base of the bag by silk threads through the tube. The bag which I use is slightly modified from Pilcher's pattern, and is mounted upon part of a special clamp, one arm of which descends into the bladder; counter-pressure is obtained by another part of the instrument ending in a small plate, which supports the area around the central point of the perineum (Fig. 1). In this way two fixed points are obtained, and between them the rubber bag is held and there distended to the necessary amount. When once in position it is secure, and does not get out of place if the patient moves about and turns on to his side, or even on to his face. Fig. 2 shows that the dimensions of the clamp can all be varied at will, so that it can easily be adjusted to suit any size of patient. The structure of the rubber bag is shown in Fig. 3. It is made in two sizes.

Method of Using Clamp and Bag.

he silk web catheter through which the bladder has been ended is left in position during the enucleation of the prostate, s being usually done through a 4-inch incision and without the of a finger in the rectum. If a preliminary cystostomy exists atheter is passed before the operation starts. After the prostate been removed and the cavity explored to ensure that no tions of adenomatous gland remain, the end of the catheter drawn up into the bladder until a stout piece of catgut can threaded through its two eyes. The bag has been previously tended lightly and mounted upon the bladder arm of the trument, which it fits tightly, and where it remains ready in

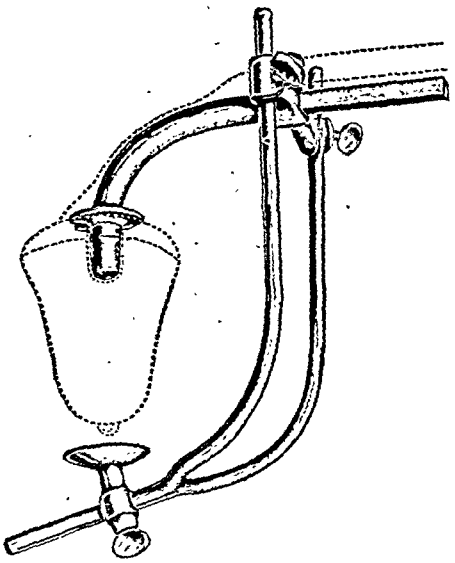

FIG. 2.—The haemostatic clamp.

position. One end of the catgut is now passed through the hole at its apex and knotted to the other near the catheter. This is then withdrawn from the urethra by an assistant, thus pulling upon the bag while the operator pushes it into the prostatic cavity. One strand of the catgut is then cut, and all of it pulled away from the bag through the urethra. If for any reason no catheter is employed, the operator can introduce the bag without the help of traction from below, but it is not quite so easily done.

The patient's scrotum, penis, and groins, which have been included in the area "prepared" for operation, are now uncovered for a moment. As a further precaution the operator covers his left hand and forearm with a sterile towel. Through this he holds the perineal half of the instrument and places it in position, while his assistant, having, if necessary, moved the scrotum and penis with holding forceps, now tightens the two screws, thus fixing together the two halves of the clamp. The bag is distended with water to the required extent, and its tube is then clamped with pressure forceps. It will be found that it is firmly fixed in position between the arm within the bladder and the counter-pressure afforded by the plate. Haemostasis is thus secured.

FIG. 3.—Sectional diagram of the haemostatic bag.

A drainage tube is inserted, and the wound closed round it and the arm of the instrument along which lies the tube leading to the bag. The pressure is sometimes lessened after four or five hours, but if haemorrhage recurs it is again restored. More usually it is maintained for about eighteen hours. Then, or rarely forty-eight hours after the operation, the screws are undone, and when the drainage tube has been withdrawn the instrument and bag are removed. This is effected without difficulty, and there is no need for any anaesthesia, for the empty rubber bag slides out of the prostatic cavity very easily, and in a manner contrasting markedly with the painful process of removing packing. A small drainage tube is placed in the bladder, which is then irrigated.

There are no special points about the subsequent treatment of the case. Pilcher has pointed out that another advantage which the haemostatic bag has over packing is that it always brings pressure to bear upon the circle of torn vesical mucous membrane, as can be seen in Fig. 1, and it is from here that much of the bleeding occurs; the sides of the bag which I use are sloped to secure this (Fig. 3). But it does more than this, for it carries the vesical mucous membrane down into the prostatic cavity, and encourages it to adhere there, thus lessening the risk of formation of a ring of scar tissue which may subsequently contract and cause obstruction.

It will be seen, then, that by means of the haemostatic bags which Hagner and Pilcher introduced haemorrhage can be stopped with more certainty than by other means. It is cleaner than packing, and it is more easily removed. The clamp which is here described ensures that its position and the tension which it exercises shall be unvarying until such time as the surgeon wishes to make any alteration, and that this is effected without any possibility of damage to neighbouring structures.

I am indebted to Mr. Schranz of the Genito-Urinary Manufacturing Company for the skilful construction of the instrument, and to Dr. Georges Dupuy for the illustrations.

AIDS TO PALATAL SUFFICIENCY AFTER CLEFT PALATE OPERATIONS.

BY

SIR ROBERT WOODS, M.CH., F.R.C.S.I.,

LARYNGOLOGIST TO SIR PATRICK DUN'S HOSPITAL, DUBLIN.

EVERY operator on cleft palates is familiar with the difficulty of restoring speech after closing the cleft. Where the child is reasonably young, careful training is often all that is required, and about such cases I have nothing new to say. But there are many in which, while the operation turns out as good as could be hoped for, yet the distance between the palate and the pharyngeal wall is too great for any effort the muscles are capable of making.

When the patient is old enough to understand, the best preliminary step is to teach him or her to practise before a looking-glass so as to get voluntary control of the constrictors of the naso-pharynx. This exercise develops the muscles, and as they strengthen, it sometimes happens in a moderate case that complete voluntary closure may be counted upon, after which good speech is only a matter of teaching. But there are others in which no amount of training overcomes the difficulty of shutting off the nasal cavity; nevertheless, improvement is often possible.

When the opening left after the post-nasal sphincter has contracted is small, I have had good results from injections of paraffin wax behind the sac of the pharynx. This forms a cushion or boss against which the soft palate makes a contact, which it just failed to make before, thus eliminating the nasal quality from the labials and dentals. For this purpose I have used Mahu's paraffin syringe, the end of the needle being turned upwards at about the angle of a post-rhinal mirror. The operation is painless under local anaesthesia. I assume there is some risk of infection during injection, but it has not happened in the few cases in which I have employed the method.

It is, however, concerning the worst cases of this kind that I want more particularly to write—cases where a good and successful operation has been performed, but where the hiatus behind the palate is so great that they look quite hopeless. Though I have but one case to place on record, it was one in which the gap was so bad, and the result so good, that I think myself justified in suggesting that in the future few should be abandoned without giving the method a trial.

In 1925 I was consulted by a lady, aged over 30, on whom quite a good operation had been performed, but the opening behind the palate was literally huge. She felt her disability very acutely, and was most anxious that something should be done, so I consented to try. I thought that by snipping away the mucous membrane of the naso-pharynx at the level of the palate, so as to form a linear wound, there might be some hope that, after cicatrization when the scar contracted, the defect might be so reduced that she could supplement it by training the muscles. I accordingly snipped away a ring of tissue, but the result was most disappointing, and as a remedy proved quite futile. The wound healed with the most aggravating rapidity, leaving her neither better nor worse for the attempt.

I next tried diathermy. This produced a slough of the superficial tissues of the sides and back of the pharynx and the edge of the soft palate, including the uvula. The throat was very sore for some days, and deglutition was, of course, difficult. She suffered no rise of temperature, and after a week or so the wound cleaned off and contraction began. This continued until, about three months later, the opening was reduced to the size of the tip of a small finger. I found then that it was quite easy for her to close it completely by an effort of will. She thus had all the physical conditions necessary for normal speech.

She returned to London, where she was employed at secretarial work, and by my advice put herself under the care of a tutor for defective speech. It will easily be understood that the faulty voice production of a lifetime was not to be overcome after a lesson or two, but she was diligent and intelligent, and she gradually acquired complete control so as to be able to talk quite correctly, if at the first a little pedantically. Her greatest obstacle was in dispensing with the glottal stop of which such people make so much use as a substitute for labials and dentals.

RIGHT BRANCH BUNDLE BLOCK.

BY

W. S. MALCOLM, C.M., M.D.,

ELECTROCARDIOGRAPHER AND ASSISTANT PHYSICIAN, DUNDEE ROYAL INFIRMARY.

ELECTROCARDIOGRAPHY is the only means of discovering the existence of disorders of heart conductivity in the terminal branches of the bundle of His. Right branch bundle block does not imply a disturbance of rate or of regularity, and, being an expression of myocardial degeneration, recognition is of importance for prognosis. It may be that visible evidence of abnormal activity of the left ventricle is present and that a reduplicated first sound is heard, but these signs are not pathognomonic of the condition.

A normal electrocardiogram is shown in Fig. 1: P represents auricular activity and QRST ventricular; QRS is called initial ventricular, for it is recorded as the ventricles are passing into activity, and T is terminal ventricular. The ventricular curve arises from the change of potential induced as the wave of contraction passes through the ventricles, and it is really the algebraic sum of the deflections which would be produced by the right and left ventricles contracting separately. Lewis[1] has shown that R of Lead 1 and S of Lead 3 are mainly left ventricular events. These preliminaries help the understanding of what takes place when the contraction stimulus fails to pass along the right branch in right branch bundle block.

Having traversed the bundle of His, this stimulus finds in right branch block the right branch impermeable, or that conduction is slower than it is along the left branch. Consequently the contraction stimulus reaches first the left

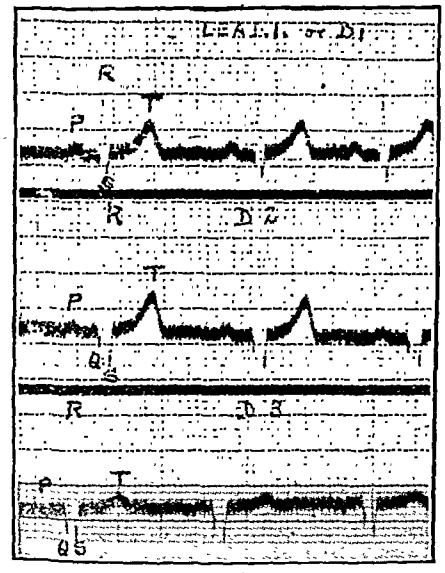

FIG. 1.

ventricle, and if the right branch is impermeable the stimulus passes from left to right ventricle through the medium of myocardial fibres common to both ventricles. Thus the right ventricle is later than the left in passing into contraction. Now QRS represents the initial activity of both ventricles; consequently the duration of the initial ventricular contraction is prolonged. The lengthening of the QRS period is the principal feature of branch block. Normally it does not exceed 0.10 second, and in health its duration is less than one-third of the total duration of ventricular activity (QRST). In branch block it exceeds

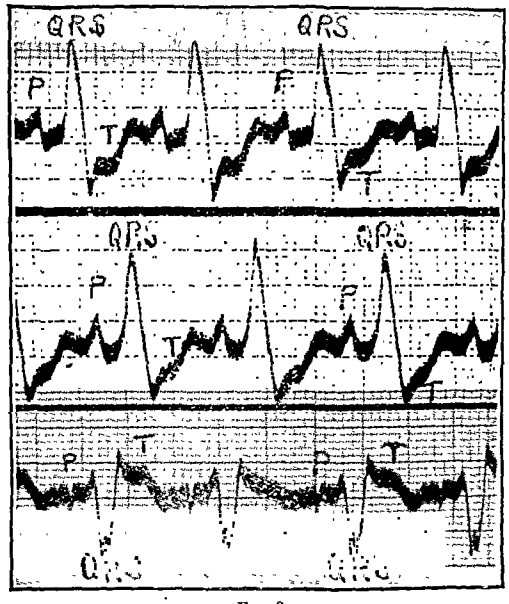

FIG. 2.

0.10 second and it lasts longer than one-third of QRST. The fact that the contraction concerns first the left ventricle and then passes to the right explains the beading or notching frequently seen on the group deflection QRS.

The second characteristic of branch block is that the terminal wave T of the ventricular deflection has a direction opposite to that of the initial one (QRS). If QRS is upward, T is downward, and if QRS is downward, T is upward. Having decided from these two signs that there is a block of one branch of the bifurcation of the bundle of His, we have to determine whether it is left or right. If the main spike of the QRS group is upward in Lead 1

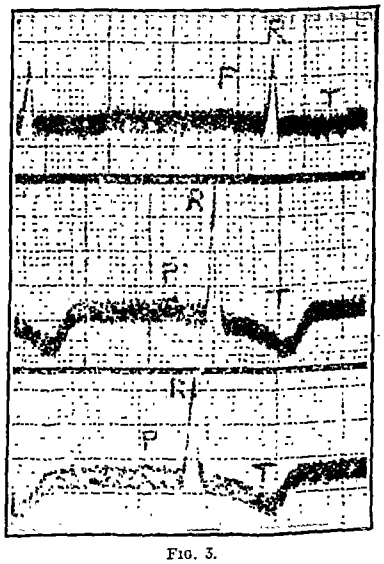

FIG. 3.

and downward in Lead 3, there is a condition of predominance of the left side, for R1 and S3 are mainly left ventricular events.[1] This implies that the left branch is intact and that the right fails in conductivity, the condition of right branch bundle block.

The condition in a spinster, aged 60, with signs of heart failure with oedema and congestion, clubbed finger-tips,

triple rhythm, daily range of temperature 97° to 98.4°, is illustrated in Fig. 2. The diphasic ventricular complex is shown with characteristics already noted. The initial phase of ventricular activity is necessarily prolonged, for the stimulus has first to traverse the left ventricle before reaching the right.

A record closing five months' observation is shown in Fig. 3. The tracing shows reversion to the physiological type, but the steep negativity of T2 and T3 is ominous.[3]

Of three cases encountered two were males. All had reached the degenerate period of life, with thickened arteries and high systolic and diastolic readings, and with symptoms indicative of cardiac insufficiency. The associated cardiac lesions were respectively mitral, aortic (Wassermann reaction positive), and hypertrophy (with renal cirrhosis), the common factor being myocardial with degenerative arterial change.

Branch block adds to the gravity of prognosis, as the much quoted statistics of Willius[5] show. In an analysis of twenty-four cases of branch block, Cowan and Bramwell[4] found that in only one case did the block show a tendency to disappear. Lewis,[6] Ritchie,[7] and Hewlett[8] have recorded cases in which block was present as a temporary manifestation in association with febrile or toxic disturbance, as in the case here quoted. In Hall's case[9] the block was permanent but stationary, in contrast with the ordinary rule that the lesion, if chronic, is progressive.

I wish to acknowledge my indebtedness to Dr. Foggie, in whose ward the patient was.

TUBERCULOSIS AND MILK.*

BY

NATHAN RAW, C.M.G., M.D.,

LORD CHANCELLOR'S VISITOR IN LUNACY.

IN the BRITISH MEDICAL JOURNAL of 1903 I ventured to suggest that bovine bacilli conveyed by milk played an important part in causing tuberculosis in children. This has since been confirmed by many other workers, and is now accepted as a serious menace to child life.

The International Congress on Tuberculosis which was held in Washington in 1908 will always be remembered on account of the discussion which took place on the part played by the bovine bacillus in the production of tuberculosis in man. We were honoured on that occasion by the presence of the great master, Robert Koch; and those of us who took part in the secret session will never forget it. Up to that time Koch had not publicly admitted that bovine infections in man were possible, but he later modified his views, and we are all now agreed that an important amount of tuberculosis, especially in children, is directly conveyed from the dairy cow.

At that conference I read a paper, entirely based on clinical and hospital observation, pointing out the possibility that surgical tuberculosis in children, such as enlarged lymph glands, mesenteric disease, and affections of bones and joints, were separate and distinct infections from those of pulmonary tuberculosis, and might be caused by milk. The brilliant pioneer work of our president, Thebold Smith, on the role of the bovine bacillus, stimulated many workers, myself included, to further investigation, and it is particularly fitting that, eighteen years afterwards in this city of Washington, Dr. Park should tell us of the immense reductions in infant mortality and suffering as the result of their researches.

The incidence of bovine tuberculosis varies in different countries, and depends upon the extent to which cattle are infected with tuberculosis and the amount of uncooked milk, butter, cheese, and other dairy products consumed. In England and Scotland dairy cows are very heavily affected, with the result that surgical tuberculosis is very common in children.

In the light of our present knowledge we cannot say with certainty which particular strain of bacillus has caused the infection. We are accustomed to recognize three types of tubercle bacilli: human, bovine, and avian. I feel convinced that there are several intermediate strains of bacilli, which we cannot yet recognize with certainty, and it is not possible to say without bacteriological and animal tests to which group those from any lesion belong. For this reason, for the purpose of determining milk infections, clinical and hospital evidence is valuable.

Pulmonary tuberculosis is in a class by itself, and is practically always caused by the human type of bacillus, which also causes laryngitis, secondary intestinal ulceration, and fistula. It is rare for such cases to develop any other lesions. On the other hand, bovine infections in human beings rarely cause pulmonary lesions; in fact, they seem to be antagonistic to each other, and it is possible that a primary bovine infection, such as enlarged neck glands, may produce immunity against pulmonary tuberculosis for life.

Should this theory prove correct, the beneficial effects of sterilization of tuberculous milk may be followed by diminished resistance to human infection in the form of pulmonary tuberculosis. In any case it is imperative that the milk supply be pure and safe for children.

Avian bacilli, though considered to be non-pathogenic to man, may contaminate a milk supply, but with what effect we do not know. In Denmark the danger of infection of pigs by avian bacilli is so real that legislation has been introduced forbidding chickens on the farm.

To sum up. In my opinion—

Human bacilli produce:

1. Pulmonary tuberculosis.
2. Tuberculous laryngitis.
3. Secondary intestinal ulceration.
4. Fistula in ano.

Bovine bacilli produce:

1. Enlarged lymph glands.
2. Abdominal tuberculosis.
3. Lesions of bones and joints.
4. Meningitis.
5. Acute miliary tuberculosis.
6. Lupus.
7. Rarely, secondary extension to lungs.

These infections are antagonistic to each other, and human and bovine bacilli are rarely found in the body at the same time. The practical measures that should be taken against bovine infection are eradication of tuberculosis from dairy cows and pasteurization of all milk for human consumption.

Eradication will for a long time be impossible; pasteurization is a safe and certain remedy. The results in several large cities where compulsory pasteurization is law are truly wonderful, and have resulted in the saving of the lives of thousands of children every year, and endless pain and suffering with lifelong deformity. I sincerely trust the splendid pioneer work in New York and other American cities will soon be universal. At the same time it is imperative that every effort should be made to stamp out tuberculosis in dairy cattle.

It is estimated that in England about a million dairy cows are affected with tuberculosis. The cows with udder disease are, of course, the most dangerous. The compulsory seizure, isolation, and slaughter of these cows is a slow, laborious, and very costly procedure. The new Tuberculosis Order recently made in England will in time have a most beneficial effect in removing diseased cows from dairy herds, and so reducing the amount of bovine infection in children. In addition it is to be remembered that the financial loss to stock breeders and farmers from tuberculosis is enormous.

The question of the possible immunization or vaccination of cattle against tuberculous infection is of supreme importance, and as practically all cattle are born free of any tubercle—infection taking place after birth—the problem ought to admit of a solution.

I would like to lay before this conference the results of my own work, during the last eighteen years, in attempting to produce immunity in animals against tuberculosis. In 1906 Professor Koch gave me in Berlin a pure culture on

* Read before the International Conference on Tuberculosis, Washington, October 2nd, 1925.

glycerin agar of human bacilli from a virulent case of pulmonary tuberculosis. Professor Calmette, then of Lille, supplied me with a virulent bovine culture from the mesenteric glands of a cow, and Professor Bang of Copenhagen gave me a culture of avian bacilli from the liver of a chicken.

These cultures have been subcultured on glycerin potato and transferred to glycerin agar every month for twenty years in my laboratory, and the present growths represent the 241st generation. At the end of 1914 I was afraid the work would be interrupted, but I took the cultures with me to France, and as I had a good laboratory in the hospital I was able to continue the subculturing there for the next four years. The growths are still profuse and true to type, but they are now completely non-tuberculogenic and non-pathogenic to animals.

Every year since 1906 I injected these bacilli into animals with a view of testing their pathogenicity; until 1913—that is, the 84th generation—I noticed no change in their virulence. After that time attenuation became marked, and in a series of inoculations of these bacilli into animals in 1914 they were observed to be avirulent. These experiments conclusively prove that virulent tubercle bacilli can be attenuated to such a degree as to be avirulent and non-pathogenic to highly susceptible animals. Some hundreds of animals have been inoculated to test the powers of immunization of healthy animals, and with excellent results. For the purpose of immunizing calves a vaccine was prepared from attenuated cultures of human bacilli. It is a bacillary emulsion of killed bacilli, and contains all the products of the bacillus. Living bacilli are never used; they are destroyed by heat before preparation.

Calves that are to be immunized should be separated from the mother at birth and fed on healthy milk for a week, when the first dose of vaccine is given; this is followed a week later by the second dose. They then associate with the other animals. The injection is given hypodermically in the usual way, under the skin of the abdomen, with strict antiseptic precautions. The method is only applicable, of course, to healthy animals.

During the last four years over 600 calves in valuable pedigree herds have been vaccinated by careful veterinary surgeons, and tuberculin tests at intervals of six months have so far been most satisfactory; the duration of immunity in 120 calves has been over three and a half years.

The problem of tuberculosis resolves itself into the question of immunity, and, in my opinion, we want to aim at producing an immunity in the animal against the amount of infection it is likely to encounter in ordinary life. It is almost impossible to immunize any animal against a lethal dose of virulent culture. The protection of the community by some safe scientific method of active immunization is the only effective way by which this preventable scourge can be eradicated.

Turning to the question of human immunity the problem is much more difficult, as children are susceptible to both human and bovine infection. At the special request of the parents in a large tuberculosis colony to which I was attached, and where each father has pulmonary tuberculosis, I gave all the children, over a hundred in number, two doses of protective vaccine prepared from dead attenuated bovine bacilli, with the object of protecting them from human infection. So far they appear to be healthy, but it will require at least ten years of observation before we can give any definite opinion as to its efficacy.

In conclusion, I am of the opinion that it is possible to immunize cattle against ordinary infection by using killed cultures of attenuated human tubercle bacilli, in precisely the same way that we can give immunity to man against ordinary infection of typhoid and paratyphoid by using dead cultures of typhoid bacilli. Animals cannot withstand large doses of virulent bacilli as a test of immunity, and I cannot see that it is necessary to give them. Our aim is to protect animals and children against the ordinary infection they are likely to meet with in life, and not against a lethal laboratory dose of virulent bacilli. In my opinion it is not necessary to use living organisms for the purpose of producing a relative immunity against tuberculosis.

TREATMENT OF TUBERCULOSIS.

A NOTE ON THE EFFECT OF COLLOIDAL ANTIMONY.

BY

PERCY MOXEY, M.B., CH.B., D.P.H.,

CLINICAL TUBERCULOSIS OFFICER AND DEPUTY M.O.H. FOR THE PORT AND BOROUGH OF SOUTHAMPTON.

PULMONARY tuberculosis is so widespread and accommodation in sanatoriums is so limited that any form of treatment to be of much value to the community at large should be one than can be carried out under ordinary conditions with the patient living at home, or even continuing his work. It should also be such as can be carried out by the patient's own medical attendant.

In looking for a drug which would at least alleviate some of the most distressing symptoms of phthisis it occurred to me to make trial of antimony, which has been used with some success in the treatment of leprosy, kala-azar, and bilharziasis. The difficulty at first was to find a preparation which caused no unpleasant symptoms. A 2 per cent. solution of tartar emetic in normal saline was tried for some time, half-grain doses of antimony tartrate being administered intravenously twice a week. Improvement followed a course of these injections, but the immediate effect was often a feeling of collapse.

I next decided to try collosol antimony (Crookes's) in 1/2 c.cm. doses intramuscularly twice a week, and found that with this there was no shock, and it could be given in the out-patient clinic without fear of untoward symptoms. On the day after the injection the patient feels a little tired, but when this has passed off there is a distinct improvement; appetite increases, the breathing becomes easier, and the patient feels much brighter and more alert. The effects on the lesion seem to resemble those produced by sanocrysin, but without its dangers; for a week or two moist signs increase and the expectoration becomes more profuse, but these eventually diminish, the evening temperature drops slowly to normal, and thereafter pursues a much more level course.

The colloidal antimony is most conveniently injected into the flexor muscles of the forearm, and in some thousands of injections during the past year I have had no ill effects from it. There is often a little pain with the first few doses, but this is seldom complained of at subsequent injections. The dose at first is 0.5 c.cm., increased later to 1 c.cm. The temperature is as a rule improved after three or four injections, but if the pyrexia persists, both the quantity and the frequency of the injections may be increased. In severe cases I have given daily injections for a fortnight without ill effect. Occasionally when a patient has not reacted to intramuscular injections I have given them intravenously, with immediate result; on the other hand, intravenous injections not uncommonly cause some malaise.

How long the injections of antimony should be continued it is as yet too early to say, but in general one would suppose that they should be persevered with until the physical signs have cleared up.

To patients with troublesome cough during the day I give also a mixture thrice daily of vinum antimoniale 10 minims, oxymel scillae 1 drachm, in half an ounce of water. This reinforces the antimony administration, and also soothes the cough and assists expectoration. For the morning cough, often so distressing, I give asparagin 1 grain first thing, dissolved in a drachm of water; this loosens the tenacious sputum. At night I give the liquid extract of *Sanguinaria canadensis* in 2-minim doses in water to allay bronchial irritation and promote a good night's rest. The two drugs asparagin and sanguinarin have been used by me now for many months and in over 200 cases, and I am convinced of their value, although where there is haemoptysis or even blood-stained sputum I omit the sanguinarin. In very acute cases I administer these drugs alone for a week or two before beginning the antimony injections, lest the antimony, by increasing congestion in the lungs, might do fatal injury. If the sanguinarin irritates the stomach it should be discontinued. For pleuritic pain in phthisis I use a simple liniment of turpentine, alcohol, and compound camphor liniment in olive oil, to be rubbed on the chest and back daily.

It is only right to mention that the temperature often drops directly after administering asparagin and sanguinarin, before the injections of antimony are begun.

I have satisfied myself that under the treatment detailed above a much shorter residence in a sanatorium is required than has hitherto been the case, and this permits a larger number of cases to pass through the sanatorium in a given time. Even in Stage 3 cases I have often found three months' in-patient treatment sufficient to enable them to return home greatly improved with a fairly normal evening temperature and fit to attend the clinic regularly. So far I have treated about 200 cases in this manner, with most satisfactory results on the whole, and but few failures.

It is, of course, essential that the patient should continue to lead a quiet life with sufficient food and comfort until he is fit to resume work. For patients with much bronchial irritation exposure to cold, damp, and foggy weather is harmful; certainly in such cases the fresh-air treatment can be much overdone.

Much more work with this treatment is clearly necessary before it is possible to say whether the results are better than those produced by other methods; but my own observations are distinctly encouraging, and it is with the hope that other workers in this field will give it a trial and report their results that this preliminary note has been written.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

THE TREATMENT OF VARICOSE VEINS BY ORGANIC ARSENIC INJECTIONS.

IN the BRITISH MEDICAL JOURNAL of October 2nd, 1926 (p. 614), are described the effects of treatment by injections of quinine and salicylates, causing thrombosis of the diseased vein.

About 1910, when "606" was first introduced, I had occasion to treat a mild case of inherited syphilis. The patient was sitting with the arm resting on a table. When I had injected about 10 c.cm. of the fluid the patient fainted—it may have been due to the view of the 300 c.cm. to be yet injected. We knew little or nothing of the effects of the Ehrlich-Hata preparation except what we were warned against, which was not of much use as the effect happened before we could prevent it.

Later in the day the patient again presented himself, determined to go through with it. Knowing that he had a varicose vein in his leg I decided to inject into this, as I was under the impression that it would be expedited by being put into a large-bore vein, without thinking that no more could go through the needle than the bore would transmit, but knowing, however, that the rule was not to touch the varicose vein unless it was to be excised at once, which I had no intention of doing at the time.

I succeeded in completing the injection at this sitting, but as a precaution had the patient lying on the operating table. I at once bandaged the leg as usual and allowed him to go home. I saw him three days later, when I was informed that the varicose condition had vanished. On examination the vein could not be seen. It has remained well ever since, and no bandages have been worn subsequently. From this experience I have ever since used injections of galyl, kharsivan, neokharsivan, or novarsenobillon, with the same effect, but I have now adopted the regular anti-syphilitic course of treatment in all cases, being convinced that the varicose condition is syphilitic and possibly only hereditary in origin. Piles I deal with in the same way, with most satisfactory results. I have had occasion to treat two sleep-walkers. The first had a very bad history of apoplexy in his father, mother, two brothers, and a sister, who all died between 35 and 43 years of age. This man used to walk in his sleep and screech as if he were being stabbed with a knife, frightening everyone around; he was fast asleep all the time. He had "Circe's girdle" well marked round the upper edge of the liver. One injection of galyl stopped his nightly peregrinations. I lost sight of him during the war, but met him afterwards, when he told me that he had never been troubled with sleep-walking but had developed rheumatism, probably syphilitic in nature. The second sleep-walker I injected at once without inquiring into the family history, though I had a suspicion that it was tainted. He also ceased to walk in his sleep.

Varicose ulcers I always treat by injections of the arsenical compounds into the vein or veins below the ulcer. I apply a non-irritating dressing to the ulcer and keep the patient in bed until it is soundly healed. This usually, in a very old and hard-edged ulcer, takes about fourteen days. The scar becomes very dense and unyielding; it does not recur if the treatment is carried out to the end. I give the first injection on the day of seeing the patient, the second in fourteen days, and the third three months later. Throughout this period of fourteen weeks I give Hutchinson's formula for mercury, three pills a day. If the gums become painful I stop the pills, to begin them again as soon as the gums are normal. During sixteen years' experience of treating syphilities I have noticed that the veins in the arm, as well as in other parts of the body, always become narrowed to the normal, where previously they had been more prominent than they ought to be. They further always remain pervious, so that varicose veins can be cured by injection without causing pain or thrombosis. In no case have I seen recurrence of the varicose condition.

Upington, Union of South Africa. W. M. BORCHERDS.

THE AFTER-TREATMENT OF MASTOID OPERATIONS.

IN the report of the discussion in the Section of Laryngology and Otology of the Annual Meeting on the after-treatment of mastoid operations, published in the JOURNAL of December 18th last, no mention is made of the use of paraffin preparations as a substitute for gauze packing in the radical mastoid cavity. I am so convinced of the advantages of the use of such preparations that I take this opportunity of very strongly recommending them. I claim no originality, having read of the method some time ago in a French journal, to which, unfortunately, I cannot now find the reference. Either the proprietary preparation ambrine, or the B.P.C. preparation No. 7 paraffin, can be used. The latter consists of a mixture of soft and hard paraffin, with resorcin, eucalyptus, and olive oil, and has a melting point of 48°. All that is necessary is to melt the preparation in a test tube in a water-bath and pour it into the cavity. It can be removed without difficulty by picking out with forceps. My practice is to renew the paraffin at weekly intervals. I employ it whether a skin graft has been used or not. The advantages of its use are: (1) The cavity heals with astonishing rapidity, probably owing to the absence of trauma to the spreading epithelium. (2) It can be introduced (and removed) painlessly, and by the unskilled, with the certainty that the whole cavity will be filled. (3) Presumably, owing to (1), the discharge diminishes very rapidly.

PSEUDO-MUCINOUS CYSTADENOMA OF THE OVARY.

THE combination of a dermoid cyst and a pseudo-mucinous cyst occurring in the same ovary is very uncommon, and is worthy of record.

A woman, aged 48, complained of increasing abdominal distension; she was found to have a large ovarian cyst. The operation was performed by Mr. Rodney Maingot, F.R.C.S., and the removal of the large cyst presented no difficulties; it weighed 12 lb., the tumour consisted of two distinct parts—a large thin-walled portion which lay anteriorly and presented the macroscopical characteristics of a pseudo-mucinous multilocular cystadenoma, and a small hard thick-walled cyst which was situated posteriorly. The latter did not communicate with the former, but was loosely attached to the main tumour by areolar tissue. On section it contained a great quantity of hair, and thick pultaceous matter.

The large cyst, on microscopical examination, showed no signs of malignancy, and Dr. A. B. Rosher confirmed the diagnosis of pseudo-mucinous cystadenoma of the ovary.

Reports of Societies.

MIGRAINE.

A DISCUSSION on migraine was held by the Section of Medicine of the Royal Society of Medicine on February 22nd.

Dr. C. P. SYMONDS, in introducing the subject, said that the great need was for clearer definition. Very little was known about the etiology and mechanism of headaches in general, but for the purpose of scientific investigation the term "migraine" should be reserved for a group of cases which in their clinical characteristics were so well defined that there would be no difficulty in separating them from the main body of obscure recurrent headaches. He defined migraine as a liability, dating from early life, to recurrent attacks of headache which were at one time or another associated with characteristic visual or sensory disturbances and were frequently accompanied by nausea and vomiting. This definition excluded a number of cases of recurrent sick headache which might probably be regarded as incomplete migraine, but the narrower definition would help to focus attention upon a few outstanding clinical facts. In the etiology of migraine heredity was generally recognized as of first importance. Given inherited liability, which was the rule rather than the exception, what was the precipitating cause? Some said eye-strain; but he thought that in the particular group of cases under discussion this was rarely an important cause of the attacks. There were recurrent headaches due to errors of refraction and muscle balance which in many cases could be cured by proper correction, but these should not be included under the head of migraine. He suggested that migraine was due to a susceptibility of the cortical vessels to spasm of their walls, but there was nothing to show by what means this spasm was provoked, though mental stress in some way, at present obscure, played an important part. Possibly the reaction was of a chemical nature and due to the action upon the vessel walls of toxins derived from neural metabolism. Other toxins derived from faulty metabolism of fats, sugars, or proteins might be responsible. On the experimental side further research should be made along the path opened by Howard Florey into the effect of various chemical substances, such as cholesterin, acetone derivatives, acids, and alkalis upon the cortical vessels, either when applied directly or introduced into the blood stream. On the clinical side a number of cases of true migraine coming within the definition he had given should be investigated by the clinician and biochemist in collaboration before, during, and after the attack. From a comparison of the results obtained by two or three teams working upon these lines some positive knowledge might be gained as to the part played by diet and faulty metabolism in the causation of attacks. With regard to treatment, régime was of first importance. The physician could not forbid worry, but he could prescribe conditions of work, recreation, and diet which were of the greatest value. Of drugs, luminal in some cases and liquor trinitrini in others, given regularly as preventive measures, had proved useful.

Dr. HUGH THURSFIELD (*President of the Section*) described the case of a medical man of his acquaintance who had suffered from migraine for some twenty years. The sufferer's own account of his visual disturbance was that he saw a central clear space of elliptical shape surrounded by a dazzling border, beyond which was a misty area. On closing the eyes the effect changed to a central dark spot in a dazzling frame beyond which were rapidly revolving bodies. These phenomena lasted usually from ten to twenty minutes; sometimes the right eye only was affected, sometimes both eyes. Headache as a rule followed about half an hour afterwards. The attacks were most commonly the sequel to slight digestive disturbance, sometimes associated with nervous exhaustion, following hard work, and especially worry. Dr. Thursfield added that in these cases symptoms tended to disappear with advancing years.

Dr. A. F. HURST thought that Dr. Symonds was entirely wrong with regard to the pathogenesis of the condition. The speaker quite agreed that at bottom there was a constitutional inherited factor—an abnormally irritable centre somewhere in the brain. He agreed also that any interference with general health increased the irritability of that centre so that attacks became more frequent. But he thought that far and away the most important provocative influence was eye-strain. Probably in every case eye-strain was an important factor, in many cases almost the only factor. The reason why there were such differences of opinion was that oculists varied so much in the way they examined patients. In a woman who from 18 to 21 had suffered severely from migraine, every manner of drug and other treatment was tried. She was seen by five oculists, but none of them could find anything wrong with her eyes. Dr. Hurst sent her to another oculist, who made a certain correction; during the last ten or twelve years she had had only two attacks, and in each case because she had stopped wearing the glasses which had been prescribed.

Dr. JOHN L. MORTON said that the general practitioner had an unequalled opportunity of seeing migraine from the beginning. He had been called to children of about 8 or 10 with violent recurrent bilious attacks which were really attacks of migraine. In young adult life the most typical cases were seen. The most important factor, he was sure, was eye-strain. All first-class oculists were by no means equally successful in finding a defect. The detection of the small errors of refraction and muscle balance which were the stimulating factors in migraine might be very difficult. But other causes in his experience were uterine and menstrual disorders, intestinal stasis, and appendicitis, and a sluggish or inactive liver. Headache was by no means the only symptom. There were people whose heads refused to ache in any circumstances, and others in whom a sharp reprimand would create a first-class headache. In some cases intolerable itching of the scalp preceded a headache for several days, spectral mists came before the eyes, and the sufferer tended to wake increasingly early in the morning. While migraine might pass off in later life, this was not always a change for the better. A tendency to nausea and irritable stomach might remain, glycosuria might appear, and arterio-sclerosis become obvious.

Dr. KINGSTON BARTON was surprised by Dr. Hurst's emphatic statement about the eyes, and thought that other causes were also concerned. It was extraordinary that when an attack of migraine was passing off the same signs were found as if the patient had cirrhosis of the kidney—extreme polyuria associated with hard throbbing heart. A large number of older people had cured themselves, in the case of women by ceasing to eat meat, and in the men more commonly by giving up alcohol. This pointed to a dietetic element in the causation.

Dr. JOHN A. RYLE said that it would be asked why this and other explosive disorders—asthma, gout, epilepsy—could not be cured; the reason was the inheritance factor. These things were not diseases but diatheses, passed on from generation to generation.

In some further discussion, Dr. FRANK COKE mentioned a case in which violent attacks of migraine had been associated with asthma due to feather-sensitiveness, and another in which a migraine sufferer sensitive to pollen was free from migraine attacks during the hay-fever season. Dr. E. A. CARMICHAEL suggested the possibility of hydrocephalus accounting for the symptoms in migraine, pointing out that migraine could be almost described as a slow form of epilepsy, and that epilepsy did occur in hydrocephalus. Dr. W. R. REYNELL also spoke of the relation of migraine to other paroxysmal phenomena. When the problem of epilepsy was solved more would be known about the nature of migraine. Dr. H. W. NOTT referred to the value of thyroid and manganese treatment in all cases in which there was a disturbance of metabolism, even with an hereditary factor. Dr. AGNES SAVILL mentioned a case in which large doses of sodium salicylate, without bromide, given daily with a good deal of water, had entirely arrested a migrainous condition, even though the glasses had remained uncorrected. Dr. H. J. MACBRIDE could not agree with Dr. Hurst's emphasis on eye-strain. Blood counts should be made during attacks, and the family history investigated for other phenomena. Dr. F. W. COLLINGWOOD, who had been a sufferer, said that he could use his eyes in reading indefinitely without fear of attack, but the precipitating cause was most frequently an exciting debate, especially on a political subject.

OBSTETRICAL AND GYNAECOLOGICAL CASES.

THE annual meeting of the North of England Obstetrical and Gynaecological Society was held in the rooms of the Medical Society of the University of Manchester on January 28th.

Local Peritonitis following Ectopic Gestation.

Dr. J. W. A. HUNTER described an unusual case of local peritonitis following ectopic gestation. The clinical details were as follows.

A woman, aged 34, was suddenly seized with acute abdominal pain accompanied by vomiting and slight bleeding from the vagina. Examination revealed some slight fullness in the pouch of Douglas, which was tender on pressure; this was attributed to a retroverted gravid uterus. The temperature was normal, and the pulse 90. The patient admitted being fourteen days over her time. The following day she was much better and took up her daily routine, but on the third day there was a recurrence of abdominal pain, an increase in pallor, and the pulse rate rose to 100. On the fourth day she was still doing her work and her condition was unchanged. On the morning of the fifth day her symptoms rapidly became more severe. The abdomen was more tender, the pulse 110, and for the first time the temperature rose above normal, being 100°. In the evening she was still worse; the abdomen was distended, very tender, and rather rigid. The temperature had risen to 102°, pulse 130, and there was now a profuse and very foul-smelling vaginal discharge. On admission to hospital she was extremely pale and rather collapsed; tongue dry and brown, sordes on the lips; temperature 104°, pulse 124. The abdomen was distended and very tender, especially in the lower part; percussion showed free fluid in the flanks. A foul and dirty brownish discharge was found coming from the vagina, and vaginal examination revealed signs of early pregnancy with fullness and tenderness in all fornices. In both postero-lateral fornices tender adherent swellings were felt similar to those usually palpable in acute salpingitis and giving the impression of acute adnexal inflammation. A diagnosis of pelvic peritonitis complicating [illegible] made, and laparotomy was decided upon, a [illegible] to be spreading to the upper part of the [illegible].

On the sixth day of illness a small mid-line incision was made above the pubes. Difficulty was experienced in recognizing the peritoneum, for when it was reached dark brown fluid and bubbles of gas could be seen through it, so that incision seemed dangerous owing to the resemblance to bowel. On incising it there was an escape of gas followed by a large quantity of dark brown, very foul-smelling fluid which had been distributed throughout the peritoneal cavity; it contained some pieces of disintegrating blood clot. The pouch of Douglas was felt to be obliterated by adhesions, and both appendages were bound down, so a tube was passed down into the pelvis and the abdomen was closed, no further treatment being thought advisable. Next day the temperature fell to normal, rose to 102° in the evening, and again became normal on the third day, the patient being very much better. On the fourth day the temperature rose to 100° and she was not so well, and thereafter improvement ceased; the abdomen became hard and distended with obvious general peritonitis, and on the ninth day she died, the necropsy revealing a large purulent subphrenic abscess.

Dr. Hunter demonstrated a specimen from this case which showed a small tubal gestation in the isthmic portion of the right tube. He thought that this had obviously ruptured when the symptoms started and that a haematocele had formed in the pouch of Douglas. Five days later this had become infected, as was shown by the sudden onset of temperature and signs of pelvic peritonitis. He added that there were several points of interest about the case. First, was the infection due to a gas-forming organism, or was the gas present in the peritoneal cavity due to septic disintegration of blood clot? In support of the latter view were the facts that after operation there was no further sign of gas formation, and that at the necropsy the subphrenic abscess was of the ordinary pyogenic variety. The starting-point of the infection might be the bowel or the vagina, but it was probably vaginal, for otherwise it was difficult to explain the presence of the profuse and foul vaginal discharge. No evidence of interference could be obtained, though this was strongly suspected.

Dr. DOUGAL thought the gas was due to infection of the blood clot. He had seen a case of infection by *B. aerogenes capsulatus*, when the uterus and foetus therein showed gas spaces and gas cultures of this organism.

Induction of Labour by Ovarian Extract.

Dr. W. R. ADDIS read a paper on a method of inducing labour by the intramuscular injection of extract of ovarian residue (without corpus luteum). One c.cm. of the extract was injected into the *pectoralis major* where it formed the anterior border of the axilla. Contractions of the uterus were recognized by palpation at first, as the onset of labour was painless. The dose was repeated when the contractions began to diminish in intensity and frequency; the average time in which this occurred was about three hours. After the second injection 1 oz. of castor oil was given by mouth. Dr. Addis had employed this method in twenty-two cases in periods of pregnancy varying from thirty-six weeks to a week post-mature, and had come to the conclusion that it was nearly infallible as a method of induction of labour. In the first case only had the method been a partial failure. Furthermore, the labour induced was practically painless throughout the first and beginning of the second stage, pain only being really experienced when the presenting part bulged the perineum.

Squamous Carcinoma of the Clitoris.

Miss FRANCES IVENS (Liverpool) showed a specimen of squamous carcinoma of the clitoris associated with a broad ligament cyst which had been removed from a patient aged 84, a widow for twenty-six years.

The patient had had three abortions, all at about three months. The menopause had occurred at 50, but there had been slight leucorrhoea for twenty years. Irritation and a swelling of the vulva had been noticed for about three months, together with an aching pain in the left iliac fossa, associated with difficult, painful, and frequent micturition. A pedunculated swelling of the clitoris was found with some induration in the atrophied left labium minus, and general leucoplakia. The inguinal glands were palpable and a cystic swelling was felt in the lower abdomen pressing on the bladder. The Wassermann reaction was negative. The patient for her age was in very good condition, and the vulva and inguinal glands were excised in the usual manner. The abdomen was then opened and a cystic tumour the size of a coco-nut developing in the left broad ligament was removed by resection-enucleation. The fluid within it was clear. No attempt was made to remove the right ovary or the atrophied uterus, which was lying back buried in adhesions. The patient made an excellent recovery, and the urinary symptoms improved.

The pathological report stated that there was a pedunculated solid nodule the size of a [illegible] the surface and replacing the clitoris. [illegible] mous carcinoma with some infiltratic [illegible] d a good deal of round-celled infilt[illegible] not show malignant infiltration. The [illegible] size of a full-term foetal head; it was thin walled and covered by a layer of the peritoneum of the broad ligament.

The sequence of events was: three early abortions, probably caused by a retroversion of the uterus; then, after the menopause, an irritating leucorrhoeal discharge which lasted many years, and was followed by leucoplakia; and ultimately malignant disease at a very advanced age.

Mixed Celled Sarcoma of Ovary with Pelvic Tuberculosis.

Miss IVENS showed also specimens removed from a patient aged 59, a widow for three years. She had had eight children. The menopause had occurred six years previously, and her last child had been born twenty-five years earlier. A ring pessary had been worn for three years, for prolapse. The clinical history was as follows.

There was a three weeks' history of shortness of breath, very frequent micturition, and loss of weight. The abdomen was distended by free fluid, and a cystic tumour the size of a five months' pregnancy could be felt coming up from the pelvis. At the umbilicus a reddish swelling rather like an inflamed hernia was seen. The uterus was prolapsed. At the operation a gallon of bile-coloured fluid was evacuated. Supravaginal hysterectomy was performed with the removal of a tumour of the left ovary, twisted on its pedicle, and a smaller cystic mass growing from the back of the right broad ligament, which contained greenish yellow fluid. The umbilicus was excised.

The tumour consisted of an oval mass which appeared to arise from the left ovary; it was about the size of a full-term foetal head. The surface, which was irregular with projecting bosses, showed dilated veins and blood-stained areas. The tumour was pedunculated. On section about one-third of the mass was found to be firm in consistency and yellowish in colour; the other two-thirds consisted of cyst-like cavities with areas of softening, necrosis, and haemorrhage into the tissues. The solid portion consisted mainly of spindle cells; in some areas there were collections of multinuclear cells. The necrotic area showed mainly degenerating tissue and blood clot. The right ovary was normal in size and appearance, except for one area on the surface, which appeared to be invaded with malignant cells and was pigmented. The wall of the uterus was rather thickened but otherwise normal. A section taken near the fundus showed the uterus to be invaded by tuberculous giant cell systems. Both Fallopian tubes had thickened walls with caseation. At the umbilicus there was a subcutaneous nodule three-quarters of an inch in diameter, which was solid, dark, and haemorrhagic. It did not appear to arise from the squamous epithelium covering it, which was normal in appearance. The mass consisted of fibrous tissue, blood clot, and masses of malignant cells, many of them multinucleated.

Miss Ivens said that primary sarcoma of the ovary was one of the rarer forms of malignant growths, and probably did not occur in more than 5 per cent. of all ovarian tumours. It was characterized by rapidity of growth and the presence of ascites; pigmented forms occurred. She had not found any recorded instance of the occurrence of a mixed cell pigmented sarcoma superimposed upon tuberculosis of the uterus and Fallopian tubes, and thought it might be regarded as a pathological curiosity.

Mr. W. GOUGH had seen carcinoma and tuberculosis associated in the caecum.

Diffuse Adenomyoma Endometriomatosis.

Dr. J. W. BURNS (Liverpool) showed a specimen of diffuse endometriomatosis of the uterus in a woman, aged 39, who had been married eleven years and was sterile. Menstruation began at 13 and was of the 5-6/28 type. There had been no dysmenorrhoea nor leucorrhoea.

For eighteen months before coming under observation the menstrual periods had been becoming heavier than usual, and during the past month there had been more or less constant bleeding, with marked weakness, but no symptoms arising from the bladder or rectum. Her general condition was poor, and anaemia was marked. A smooth hard tumour could be felt in the lower abdomen reaching almost to a point midway between the symphysis and the umbilicus. Bimanually the cervix was found to be drawn up behind the pubes, and the uterus was enlarged, hard, smooth, and freely mobile. There was no swelling of the appendages. A diagnosis of fibroid was made. On opening the peritoneum some free dark blood was seen. The uterus was symmetrically enlarged by what was thought to be a fibroid which was undergoing degeneration. A portion of the sigmoid and the ileum were adherent to the upper surface of the tumour; the gut was liberated with difficulty, and a subtotal hysterectomy was performed with removal of both tubes and ovaries. The patient made a very rapid recovery.

The uterus measured, after hardening, 4 by 4 by 4½ inches, being symmetrically enlarged. The wall of the fundus measured 2 inches. The cut surface was fibrous with numerous small cavities scattered throughout; many of these cavities were subperitoneal and some contained dark blood. On the upper and posterior surface was a roughened area where the intestines were adherent. There was one small fibroid in the posterior wall of the fundus. The endometrium appeared thickened and ragged. Both tubes were small and appeared normal. The ovaries were slightly enlarged and contained several cysts which were filled with a clear straw-coloured fluid. Attached to the wall of two of these cysts was some old blood clot. Microscopical sections showed in the endometrium numerous glands with the epithelium regular and single-layered. The stroma was relatively scanty and there was no evidence of inflammatory reaction. The endometrium seemed to be spreading deeply into the muscular wall. Sections of the uterine wall showed some slight increase of fibrous tissue. The uterine wall was infiltrated with islands of tissue indistinguishable from the endometrium. Some of the gland spaces were filled with blood, especially those near the peritoneal surface. Sections of the ovaries did not show any evidence of endometrioma and there no lutein tissue was seen.

Dr. Burns said that in most of the specimens of diffuse adenomyoma which had been reported the adenomyomatous condition had been described as a tumour or tumours limited to some portion of the uterine wall. In the present specimen the whole uterine wall appeared to be permeated with the endometrial tissue. He suggested that this was a true endometriomatosis.

Professor MILES PHILLIPS asked if the condition was associated with pain, and if there was definite evidence of downgrowth from the surface of endometrium.

Dr. BURNS replied that there had been no pain and no microscopical evidence of endometrical downgrowths.

Suppuration in a Pseudo-mucinous Cyst.

Dr. LEITH MURRAY (Liverpool) described the only case of suppuration in a pseudo-mucinous cyst that he had seen in a consecutive series of 115 cysts of that nature. The rarity of this complication was interesting in view of the fact that the fluid from such cysts had been previously recommended for use in certain culture media.

A woman, aged 34, was admitted to hospital with a history of swelling of the abdomen since the birth of her last child seven months previously; there had been a more rapid development in the two months preceding her admission, but pain had been completely absent. The labour, her second, was reported to have been tedious, but otherwise natural. The convalescence was normal except that she was believed to have a pendulous abdomen and was ordered a belt. On examination the patient was in a condition approximating to the "typhoid state," with a dry furred tongue, dilated pupils, and a temperature ranging from 100° to 103°. As her pulse rate lay between 90 and 100 it was felt inadvisable to operate until a Widal test had been made; this proved negative for typhoid and paratyphoid A and B. A leucocyte count came to 16,875 cells per cubic millimetre. There was a slight trace of albumin in the urine, and a moderate amount of pus. The abdomen showed a tense cystic swelling reaching to midway between the umbilicus and the ensiform cartilage; it was bossy in shape and not tender, the abdominal wall moving freely over it. A cyst weighing 9 lb. 6 oz. was removed through a vertical incision. There was practically no ascites and only one adhesion of small intestine, measuring about one-third of an inch, on the right side, near its upper border. While this intestine was being separated a slight leakage of purulent material occurred. A swab was promptly placed over the spot, the cyst delivered entire as rapidly as possible, and the abdomen completely closed. The temperature was normal next day, and remained so during an uninterrupted convalescence. The improvement in her appearance was dramatically rapid.

The specimen showed a typical pseudo-mucinous cyst of the right ovary with one large loculus containing more than a pint of creamy pus approaching the surface at the point where the intestine was adherent; the rest of the cyst appeared to be uninfected. The contrast between the large purulent loculus and the clear pseudo-mucin in the smaller loculi was very marked. There was no twist of the pedicle. Cultures, both aerobic and anaerobic, proved sterile after forty-eight hours; no bacteria were observed in direct films of the pus. Pseudo-mucin was present, both in the pus and in the non-infected loculi, and the microscopical structure was as usual, except around the abscess cavity where only traces of epithelium were observed, and there was an intense round-celled deposit.

Dr. Leith Murray said that the interest of the case lay in the history of normal labour and in the very small intestinal adhesion. Bland-Sutton had observed that it seemed difficult to understand how ovarian cysts could become inflamed, enclosed as they were in airtight cavities, and having no communication with other organs. He considered the principal sources of infection to be the Fallopian tubes, the intestines, the appendix, and "tapping." To these must be added infection by the blood stream in systemic diseases of infective origin, as was proved by several cases of typhoid infection of ovarian cysts. Pfannensteil had expressed the opinion that infection of an ovarian cyst was usually derived from the tube or intestine—the latter almost exclusively when the cyst was adherent to bowel, or even near it if the bowel was injured or damaged from any cause.

Rupture of the Uterus.

Dr. N. E. EDWARDS (Manchester) described a case of rupture of the uterus in a multipara, aged 36, who had had four previous labours—the first instrumental, the second a breech, the third instrumental, and the fourth a normal delivery three years ago.

The pelvis was slightly contracted and of the rachitic flat type. Labour pains began at 5 a.m. and the membranes ruptured six hours later, the opinion then being that the breech presented. The pains increased until 4 p.m., when they suddenly ceased, being replaced by continuous pains in the abdomen, back, and right shoulder, and associated with vaginal haemorrhage. The patient was admitted into hospital with moderate collapse; the temperature was 97.4°, the pulse 120, and there was a trace of albuminuria. Abdominal examination revealed the foetus lying transversely with its head in the mother's right flank and free in the peritoneal cavity. The contracted uterus was felt lying over to the left side and no presenting part was felt in the vagina. The abdomen was opened and a female foetus, weighing 9½ lb., was removed; the placenta was taken from the peritoneal cavity. The lower segment of the uterus was the seat of a complete transverse rupture which began just in front of the right uterine artery and finished behind the left uterine artery, which was severed. Supravaginal hysterectomy was performed at the level of the rupture; a drainage tube was placed in the pouch of Douglas, and intravenous saline was given. The patient recovered after a somewhat stormy convalescence.

Dr. Edwards said that the rupture had not been caused by interference by the doctor or midwife. Repeated childbearing, with short intervals between the pregnancies, and associated probably with some injuries to the lower uterine segment by instruments, gave rise to atrophy of muscle and fibrosis. One of these weak spots gave way under the strain caused by the vigorous attempts made by the uterus to expel a relatively large child through a relatively small pelvis. The case might have been a breech with extended legs, and some part might have been played by toxaemia, as evidenced by the albuminuria.

EPISTAXIS IN THE TOXAEMIA OF PREGNANCY.

At a meeting of the Section of Obstetrics of the Royal Academy of Medicine in Ireland on February 4th, Dr. L. CASSIDY in the chair, Dr. BETHEL SOLOMONS (Master of the Rotunda Hospital), in opening a discussion on epistaxis as a symptom of toxaemia of pregnancy, mentioned first engorgement of the cavernous tissue of the nose as a symptom of pregnancy, and the rarity of epistaxis as a symptom of toxaemia. He then reported the case of a primigravida twenty-six weeks pregnant, admitted to the Rotunda with all the symptoms of toxaemia; these cleared to some extent, but three weeks later she returned with such intense epistaxis that it was necessary to plug the anterior and posterior nares. The urine was loaded with albumin, and the blood pressure was 240. The patient was in imminent danger of death, and labour had to be induced. After consideration of the various possible methods it was decided to perform abdominal hysterotomy under spinal anaesthesia. The preliminary morphine and scopolamine injections were so effective that stovaine was unnecessary, and the operation was performed without difficulty. The nasal plugs were removed the following day. The patient did well on water diet, but an unfortunate dietary error on Christmas Day caused marked disturbance of vision, and the ophthalmologist reported that she had retrobulbar paralysis. She was kept first on water, then on light milk diet, and was finally transferred to a general hospital, where she had improved considerably. Dr. Solomons said that epistaxis might be regarded in the same light as toxaemic accidental haemorrhage and the intra-abdominal and other bleedings in many severe types of toxaemia, but it was very rare. The severe symptoms which followed the ingestion of food had been considered to afford support to the food theory of toxaemia.

Dr. T. G. WILSON said that it was not often necessary to plug the posterior nares, but in this case it had been absolutely essential in order to stop the bleeding. If the patient had not been pregnant the loss of blood would probably have done good, as it would have reduced her blood pressure, which was very high. He thought this condition was rare. If this case had not been so urgent treatment by *x*-raying the spleen would probably have been successful, as it would have brought down the blood pressure, which he regarded as the cause of the epistaxis.

The CHAIRMAN was scarcely inclined to regard this as a case of toxaemia of pregnancy; he thought it was more a case of severe nephritis supervening on pregnancy. In the great majority of stillbirths the cause was underlying bad health of the mother. He believed that in this case the condition must have been present for some time, since it seemed to him unlikely that retrobulbar neuritis would come on twenty-four hours after the taking of solid food. Eye symptoms such as optic neuritis made the prognosis in these cases much more gloomy.

Professor A. H. DAVIDSON, referring to the termination of pregnancy in this case, asked if it would not have been less of a shock, and less danger to the patient, if labour had been induced by means of a tube, instead of opening the abdomen. Labour in these cases of albuminuria and toxaemia was usually very easy.

Dr. D. J. CANNON said that spinal anaesthesia was the best from the point of view of reducing shock, but it was supposed to be bad in cases of high blood pressure. He agreed with the chairman that the case appeared to be nephritic toxaemia rather than toxaemia of pregnancy. Eye symptoms sometimes occurred in pregnancy, but cleared up immediately afterwards. He thought that the Master had been quite right to empty the uterus in this case. In cases of nephritic toxaemia the great danger was severe deterioration of the kidney. In the *American Journal of Obstetrics* Werner had recently advocated the application of *x* rays to the spleen for various conditions; it might possibly check epistaxis also.

Dr. BETHEL SOLOMONS, in reply, said that he thought it was a case of true toxaemia; many women dated their troubles from a supposed chill or trauma, and little attention need be paid to them. The urine had been normal before pregnancy. It was a fallacy to suppose that the toxaemias of pregnancy occurred only in the later months: he had seen many examples in the fourth, fifth, and sixth months, and they were most difficult to treat. In treating the present case speed had been necessary, and therefore radiation of the spleen would not have been suitable. He did not fear the possibility of sudden diminution in the blood pressure with spinal anaesthesia. He agreed it was sometimes difficult to distinguish between a true nephritis and toxaemia. The literature on the subject of epistaxis in pregnancy was meagre.

Rupture of the Uterus.

Dr. SOLOMONS also read a communication on a case of rupture of the uterus treated successfully by plugging the rent. The patient, who was aged 35, was a 3-para, and the previous labours had been normal. She was brought to the Rotunda Hospital after having been given 1 c.cm. of pituitrin by her doctor in the second stage of labour. As there was no advance after an hour the Master had applied forceps and delivered a stillborn child. Efforts to express the placenta manually failed. On admission the patient was pulseless, only just conscious, and in a condition of profound shock. The cervix was closed, but on following the cord it was found that the uterus was separated from the fornix on the left side and the placenta lay among the intestines; it was removed. Intestines appeared at the vaginal vault, and the rent was plugged with a large tampon of iodoform gauze. Two days later symptoms of intestinal obstruction appeared, and the gauze was removed. For fourteen days she continued to improve, but there was always some distension without absolute rigidity. Symptoms of slight peritonitis then appeared, and the abdomen was drained; two pints of foul sero-sanguineous fluid escaped, and a drainage tube was inserted. She had progressed well since then, but there was still some discharge from the wound, which it was hoped to stop with ultra-violet rays. This patient would have died had laparotomy been performed, but she survived the treatment by plugging. The Master added that plugging was a valuable aid to obstetrical technique, and could be practised by the general practitioner. This rupture had been caused probably by the overdose of pituitrin in the second stage of labour; 1 c.cm. was far too large a dose. When pituitrin was given at all two or three minims should suffice, and should then only be given in selected cases.

The CHAIRMAN said that when a patient came in such a condition of shock there was nothing to be gained by laparotomy; he thought that death would have occurred had laparotomy been tried. Most of these patients, if not killed by shock, died from sepsis within ten days. He mentioned the statistics published by Döderlein from 50 cases of rupture of the uterus at the clinic at Munich during the last fifty years; 7 of the patients had been untreated and had died, 10 had had laparotomy performed, and of these 6 had recovered. The other cases had been treated in various ways, 8 in a way similar to that described by the Master of the Rotunda, and 3 had recovered. On the whole, the average of recovery had been between 40 and 50 per cent. during the last fifty years. He thought that in this case the large amount of pituitrin given was probably responsible for the condition. If shock was not too great, he thought that patients were better treated by laparotomy; but a great deal depended on the cause of the shock, and also on the time which had elapsed since the rupture had occurred.

Mr. W. PEARSON said it was very difficult in this case to decide what to do after the primary shock had been overcome, the diagnosis lying between peritonitis and intestinal obstruction. The patient had done fairly well for a fortnight, after which the temperature rose and the abdomen became distended and soft; it was plain that there was no obstruction, since if purgatives or enemata were given the bowels moved. There was a good deal of dullness in the right iliac fossa, extending across to the middle line, and the probability was that it was a case of mild peritonitis. The abdomen was opened, and there was found peritonitis, a great deal of turbid fluid, and also adhesions the whole way across to the abdominal wall.

Dr. D. J. CANNON had only encountered two such cases. One was caused by the injudicious use of pituitrin, and the baby had died; the other was a case of spontaneous rupture from a previous scar. He did not anticipate any great danger of sepsis if the gauze was left in for ten or fifteen days. He thought that if the foetus was completely in the peritoneal cavity it would be difficult to deliver it unless the scar was extended; and it would add to the shock to deliver through the vagina. In these cases he considered that laparotomy should be done.

Professor DAVIDSON had had three cases of rupture of the uterus—two after version and one following a breach. In the first case the rupture had been discovered when trying in vain to extract the placenta; the rupture was in the fornix. The placenta was removed by traction of the cord, and the hand was not inserted. He thought that this was a very good point in technique, since it might be possible thus to avoid introducing sepsis into the abdominal wall. All his cases had healed.

Dr. SOLOMONS, in reply, said that he had had three cases of rupture of the uterus during the previous three months. The patient reported had lived, one with a quiet rupture had died, and in a third case, which had occurred on the previous day, there was a spouting uterine artery; hysterectomy was necessary, and she was still alive. Plugging was the best treatment when possible, but there were some cases for which laparotomy alone was suitable. The practitioner must select his treatment. The patient reported had required much care in management; she had serum and saline injections, and it was difficult to keep her bowels free. The uterus was completely separated from the vaginal vault, and he believed that the gauze temporarily obstructed the bowel—a complication he had never encountered previously. At the time of the second operation ileus from the peritonitic fluid was the trouble.

UROLOGICAL PROBLEMS.

AT a meeting of the Liverpool Medical Institution on February 3rd Mr. FRANK JEANS read a short paper entitled "Some problems of urological surgery." Mr. Jeans said that very few cases of mobile kidney needed operation; when an operation was necessary the condition, if diagnosed early by pyelogram, required division of the so-called aberrant renal artery, and not nephropexy. Most of the cases in which the symptoms had been really relieved by nephropexy could have been treated by division of this artery—a much more physiological operation than converting an organ which was naturally fairly mobile into a fixed one. He did not believe that mere mobility of a kidney, unless it had some obstruction such as an extra artery, produced symptoms attributable to the kidney and hydronephrosis. In the case of renal tuberculosis he emphasized the insidious onset, illustrating it by the following cases: post-parturient pyelitis, gonorrhoea, and a latent bullet in or near the kidney. In these cases the patients had owed their lives to the medical acumen shown in suspecting tuberculosis in time to effect a cure by nephrectomy. Mr. Jeans mentioned an important cystoscopic sign diagnostic of early tuberculosis of one kidney—namely, a rebound at an acute angle of the colouring fluid used as an indicator. This proved the existence of thickening of the lower edge of the ureteric outlet. If this was seen it was very valuable and by far the earliest possible sign. He emphasized the importance of early diagnosis by cystoscopy because all his private patients who had had nephrectomy were well, and he had difficulty in recalling surviving hospital patients, as they came when the condition was bilateral. With regard to prostatectomy he raised the question of the "one, two and three operation," and was encouraged by results given him by Dr. R. Coope, who had made the blood examinations, to think that the two-style operation, though the second stage was more difficult, should be employed, and showed a lower mortality as the patient was in a better condition to stand it. He favoured the so-called "blind operation" for patients with high blood pressure.

Trauma as a Cause of Auricular Fibrillation.

Professor JOHN HAY and Dr. WALLACE JONES submitted jointly a paper on the responsibility of trauma for the disability of auricular fibrillation with reference to its medico-legal aspect. It was shown that trauma or physical strain was sometimes the exciting factor in the production of auricular fibrillation, which might occur as the result of a man's employment, in which case the employers were liable. Five cases were reported. In one the fibrillation was caused by a severe electric shock; a man, sitting on an electric crane, accidentally placed his forehead against the live terminals of the crane and received 250 volts of direct current. Before this accident he had been perfectly healthy, but after it fibrillation began and continued until broken by quinidine. Of the four other cases, three were men in whom no heart disease nor damage was found on ordinary clinical examination, nor did they suffer from any subjective manifestations of cardiac inadequacy before the onset of the fibrillation. In each case fibrillation followed sudden definite physical effort. In the fifth case the heart was not sound; there was evidence of slight aortic regurgitation, and the electro-cardiogram showed a right bundle lesion. Up to the time of the accident, however, this patient had comfortably continued his ordinary occupation, but while lifting a heavy "hip" on to a roof he suddenly "felt something give in his chest." Fibrillation started at that time; it had persisted, and the patient had not been able to resume his occupation. The medico-legal significance of these facts was of considerable practical importance, and it was for this reason that they had been put on record.

IMMUNIZATION AGAINST DIPHTHERIA.

Edinburgh Experience of Schick-Testing.

AT a meeting held at the Royal Sanitary Institute on February 15th, when Sir ARTHUR NEWSHOLME was in the chair, an address on immunization against diphtheria was given by Dr. WILLIAM ROBERTSON (medical officer of health, Edinburgh), who said that in Edinburgh this matter was now being undertaken enthusiastically. Before embarking on it from the public health standpoint, the method was tested out for two years in hospital. In that period the incidence of diphtheria in the hospital staff was reduced to vanishing point. Previously it had been usual for five or six nurses to be infected each year. The result of the trial was such that he did not hesitate to launch a scheme of immunization for the general population. An outbreak of diphtheria occurred at an Edinburgh high-grade elementary school, and the immunization scheme was explained to a meeting of parents and others when 500 were present, and questions were answered. A start was made, and no obstacle was offered by the local or the education authority.

It was essential that those engaged in the work should be skilled in the reading of the Schick test, as unskilled operators might place the reactions under the wrong categories. In Edinburgh the school teachers had always been most helpful in the matter, especially in preserving discipline. The proper time-spacing of the stages, the cleansing of the arms, and the keeping of the needles aseptic must all have careful attention. The degree to which parents consented to the application of the test to their children varied greatly with their intelligence and education. Among the fisher people 40 per cent. of the children presented themselves; in higher grade schools the proportion was 80 per cent. The response was better, however, when it was proved that the process was harmless. The poorer the environment, the greater was the exposure to the virus of diphtheria—that was to say, the well housed child did not run so great a risk as the child less fortunately circumstanced. In a hospital for sick children, out of 43 nurses, 25 were susceptible, and 5 out of 11 maids, nurses and maids alike being of the age-period 18 to 25. It was very important to give attention to children of pre-school age. This class was not easy to reach, because it meant the attendance of parents and guardians also. In Edinburgh, however, the response to the efforts to deal with

children of this age had been very encouraging. In these young children the Schick test could be omitted. The testing and immunization of children must be undertaken systematically and carefully. A positive Schick result might mean giving a fourth immunizing dose, but immunity might not reveal itself within the nine months, therefore parents were asked to allow a fourth dose where necessary. A very important statement he was able to make was that not one bad result had been observed among the children while they were receiving the immunizing doses, and no interruption of attendance at school need be apprehended.

The use of the Schick test was begun in various schools and institutions in January, 1924, and to the present date diphtheria prevention had been carried out in thirty-three schools and twelve institutions. The numbers were now over 10,000. The expenditure on the work during 1923-24 was £222, and during 1924-25 £442. Since this work was carried out the number of cases of diphtheria which had been notified to the Edinburgh authorities had been 23, extending over nearly four years. Of these 23 cases all but one had come under notice within the stipulated period of nine months, which was the time immunization required to be effective. Some of the cases had been difficult to recognize as diphtheria as usually seen. It was important to bear in mind that there could still be carriers of the disease among people who were naturally immune. At Edinburgh the health department had made headway and gained the confidence of the public, so that in these latter days of the work very little opposition was encountered. As a matter of fact, many of the expected difficulties were easy to surmount if the medical officer dealt with the matter in a resolute way.

Attempts were being made in Edinburgh to teach the people on health matters, and an intelligent interest was taken in the subject. Professional people were also taking advantage of immunization. In reply to the CHAIRMAN, who asked whether there had been cases in Edinburgh with any severe result later than the nine months after immunization was supposed to have been established, Dr. ROBERTSON said that only one case had occurred; this was after the expiration of two years, and was of very mild degree.

Dr. R. A. O'BRIEN said that the mixture ordinarily used for diphtheria immunization of humans was not so efficient as that used for animals; it was two or three editions old. He looked forward to a material shortening of the present troublesome procedure. He suggested a longer spacing and that the toxoid alone should be used. Toxoids could be made in the laboratory and gave a more rapid immunization than the ordinary toxin-antitoxin mixture. The great point was how to translate this process into human practice, and he envied the opportunities which were afforded north of the Tweed. He insisted that immunity was a relative term—that is to say, there were grades of immunity. All that could be expected was a reasonable immunity, one which sufficed to give reasonable protection, not an absolutely 100 per cent. protection. Occasionally people who had been immunized, and had a Schick-negative, turned up with a sore throat and bacilli present.

Dr. E. H. R. HARRIES spoke of the diphtheria immunization work being carried out in Birmingham. Diphtheria had now been practically eliminated from the nursing staffs of the Birmingham hospitals. His own experience of the Schick test dated from 1921. No person who gave a negative Schick reaction had, in his experience or knowledge, contracted clinical diphtheria. The practice was also carried out in children's and other residential institutions, and in these there had been great encouragement from the matrons and others responsible. In two or three institutions protection was also afforded against scarlet fever, though in regard to this the same security could not be felt as in the case of diphtheria. A third channel of activity was in regard to the child of pre-school age. As far as possible, re-Schicking was insisted on, but only about 50 per cent. came for this. Among 1,200 children to whom the process was applied there had been no complaint whatever of reaction.

Reviews.

THE HISTORY OF MEDICINE.

DR. C. GREENE CUMSTON, lecturer on the history of medical philosophy in the University of Geneva, and president of the last International Congress of the History of Medicine, who is well known for his interest in this subject, has now published *An Introduction to the History of Medicine from the Time of the Pharaohs to the End of the XVIIIth Century*,[1] which, though modestly described as "an introduction for the student of medicine to the history of his chosen profession," will be an invaluable source of reference to those who wisely remain students all their days. Beginning with the first dynasty of the Pharaohs, the ideas and the personalities of medicine are described in a manner which compels wonder for the amount of literary research, thought, and time which must have been devoted to its construction. Before tracing the events and characteristics of Egyptian medicine he supplies a brief introduction, and a chapter summarizing the evolution of medicine as described in full detail in the pages that follow. The introduction explains the value of a knowledge of medical history, and points out that neglect of this dutiful study exposes us to the danger of repeating the mistakes of our predecessors; the century-old dictum of Littré that there is nothing in the most advanced contemporary medicine the embryo of which cannot be found in the medicine of the past is endorsed. Although the Ebers papyrus contains little about anatomy, it appears that at a much earlier date—4000 B.C.—dissection was practised, and, indeed, that a treatise on anatomy was written by the second of the Egyptian kings, so that the fanatical horror of using the knife on the corpse had not then laid its veto on anatomical research. The influence of Hippocrates, who appears in a striking frontispiece, and the ideals and characteristics of Greek medicine are fully considered, and the school of Alexandria and the various sects which arose in medicine are passed in critical and philosophical review.

Of Galen Dr. Cumston remarks that he not only restored Hippocratic medicine but made it more attractive and systematic than before, though in this new dress it lost some of its original purity and force. After further description of the practice of medicine in Rome there is an interesting chapter on Islamic medicine; it is shown that far from being servile copyists of the Greeks, as some have thought, the Arabians not only contributed much to pharmacy and created it in a scientific sense, but were, as the comparatively modern investigations of Lucius Leclerc, G. Lebon, H. Renaud, E. G. Browne, and others have proved, independent and original clinical observers; Rhazes, the first describer of small-pox, measles, and scarlet fever, Avenzoar of pericarditis and gastric carcinoma, and Avicenna the neurologist, who seems to have recognized the difference between obstructive and what is now called haemolytic jaundice, were all hospital physicians. On the other hand, as religion prevented necropsies, anatomy and surgery made no real progress.

After accounts of the schools of Salerno and Montpellier, the sixteenth century, with its devastating epidemics, and the overthrow of the Galenic tradition, are discussed. The great events of the seventeenth and the eighteenth centuries and the medical doctrines of irritability, naturalism, organicism, and vitalism are treated in the historical and philosophical manner the author so pleasantly exercises. The concluding chapter surveys the evolution of therapeutics, and thus, like the opening chapter on the evolution of medicine, gathers the reins of the work together. Though mention is incidentally made of the nineteenth century, it does not remove the reader's regret that the author has not completed the task, considerable as it would be, of bringing his admirable summary down to the present time. Dr. Cumston defines the practice of medicine as

[1] *An Introduction to the History of Medicine from the Time of the Pharaohs to the End of the XVIIIth Century.* By Charles Greene Cumston, M.D. With an Essay on the Relation of History and Philosophy to Medicine by F. G. Crookshank, M.D., F.R.C.P. London: Kegan Paul, Trench, Trubner and Co., Ltd. 1926. (Med. 8vo, pp. xxxii + 390; 24 plates. 16s. net.)

empiricism tempered by science, and holds that it will improve if the passing enthusiasms are corrected by the philosophy and judgement which only a knowledge of the history of medicine can supply.

THE PSYCHO-PATHOLOGY OF TUBERCULOSIS.

THE study of the mental states which accompany various bodily diseases has not yet received the attention it merits. Even in such a widespread disease as tuberculosis, it is only such a dramatic mental manifestation as the "spes phthisica" that has forced itself into the clinical picture—the other mental phenomena receiving but scant notice. It is this deficiency in the study of this disease which Dr. MACLEOD MUNRO has set himself to remedy in his book on *The Psycho-pathology of Tuberculosis*.[2] The author numbers himself amongst those who consider that the psychical changes observed in tuberculous patients are not merely incidental, but constitute a well defined group which may be regarded as specifically characteristic of tuberculosis. This is not the generally accepted view, the majority of observers having been content to look on such psychical changes as reflections of individual temperamental changes, or, if extreme, as indications of some concomitant psychosis.

There are, of course, a host of possible fallacies to be disposed of before the conclusion is reached that the mental peculiarities are the result of the infection. The very fact that the disease is so widespread might, for example, account for the number of geniuses who have suffered from tuberculosis. There is also a psycho-pathology of invalidism in many cases of long drawn out illness. However that may be, there are sufficient mental peculiarities in this disease to merit a close examination of the problem; and Dr. Macleod Munro's contribution is, for this purpose, of special value. He discusses, in order, the "psycho-neuroses" of the various stages of the disease; phthisical insanity; the sexual factor in tuberculosis; the association of tuberculosis and genius—illustrating his argument with descriptions of the lives of Keats, R. L. Stevenson, and others. He has given us an interesting and thought-provoking little book, and one which should be of value to the general practitioner especially on account of the consideration given to the diagnosis of the early stages of the disease so often associated with neurasthenic symptoms, and for the interesting discussion of the value of psychotherapy in the treatment of some of its manifestations.

RECENT ADVANCES IN BIOCHEMISTRY.

MR. JOHN PRYDE, lecturer in physiological chemistry in the Welsh School of Medicine, is to be congratulated on his clear and well written work *Recent Advances in Biochemistry*,[3] which belongs to the successful "Recent Advances Series" and has been dovetailed in, so as to avoid overlapping, with Professor Lovatt Evans's book on the recent advances in physiology, which has already reached a second edition. The question of what to include and what to leave out has naturally exercised the author, but he has provided the reader with plenty of information, and, moreover, has supplied two chapters on the chemical basis of specific immunological reactions and on chemotherapy, which will specially appeal to the practising scientific medical man, but are not usually found in biochemical textbooks.

After dealing with protein catabolism and the amino-acids, colloids, and hydrogen ion concentration, he goes on, in the chapter on nucleo-proteins, to discuss the difficult problems connected with nucleic acid and the synthesis of purins. The biochemistry of carbohydrates and of fats is then taken up; for the latter the inclusive word "lipides," suggested by the International Congress of Applied Chemistry, is employed; numerous references to Professor J. B. Leathes's recent work on this subject are given. The part played by phosphorus and by sulphur in metabolism also receives attention.

The chapter on the vitamins A, B, C, D, and E (the anti-sterility vitamin), which it is anticipated will be shown not to exhaust the number that really exist, also describes the substances supposed to act in relation to the growth of simple organisms, such as bacteria and protozoa, in a manner somewhat similar to that of vitamin B in the case of animals higher in the scale. It appears, however, that such a substance, called "bios," when obtained from yeast, though it stimulates, is not essential for growth, and it is held that a distinction should be drawn between the hypothetical bodies of the "bios" class and vitamins which are absolutely necessary for the well-being of an organism. In the account of haemoglobin and the related natural pigments attention is drawn to the doubtful character of the evidence for the transformation *in vitro* of haemoglobin into bilirubin, and to the absence of satisfactory proof that the tissues of the body contain an enzyme capable of bringing about this change.

In the chapter on immunological reactions already mentioned it is pointed out that, while it must, in the absence of definite evidence to the contrary, be concluded that only protein bodies can act as antigens, it is possible that some toxic glucosides may be proved to have this property, and that the protein nature of the bacterial toxins, which are undoubtedly antigens, has not yet been established. A clear summary is given of knowledge about the carbohydrate obtained from the periphery of the pneumococcus, which is specific for the three fixed types, thus contrasting with the protein of the endoplasm of the pneumococcus, which is specific for the species but not for the type.

Finally, chemotherapy, which is so much more successful in protozoal than in bacterial infections, is discussed; the simple hypothesis of direct affinity between the drug and the parasite is no longer tenable on account of the complexity of the reactions; but, although Ehrlich's ideal of "therapia sterilans magna" has not been realized, the author is optimistic in regard to the results of further research in providing more potent antiseptics.

In conclusion, this compact work, which covers a wide field in an admirably balanced manner, should certainly be extremely popular with those members of the profession who wish to keep abreast of modern knowledge.

PHYSICAL THERAPY IN DISEASES OF THE EYE AND RESPIRATORY PASSAGES.

DR. HOLLENDER and Dr. COTTLE, both of Chicago, have presented in a volume[4] of moderate size, and irreproachable both in style and appearance, something more than an outline of what physical therapy (in which is included galvanism, the sinusoidal current, diathermy both surgical and other, radiant heat and light, ultra-violet light, and x rays) may be expected to accomplish at the present time in the practice of ophthalmology, otology, and laryngology. The book they have produced may be recommended because these methods, which have been much improved and developed in recent years, are in many quarters regarded at least with suspicion if not actually with hostility, and it is well to have an authoritative pronouncement from otologists who have clearly worked hard to reach definite conclusions respecting their value. The authors make no extravagant claims, are careful to state limitations, and have not allowed enthusiasm to degenerate into obsession. The first part of the book is devoted to a general description of these electro-physical agents and the apparatus employed. The second part deals with diseases of the eye. It appears that even cataract and glaucoma are to some extent amenable to these agents. The third part deals with the ear; and in this field a fair measure of success has been achieved. The fourth and fifth parts are concerned with the nose, throat, and mouth; diathermy occupies a prominent position here. Another part is devoted to border-line diseases such as asthma. The book should be particularly useful to the growing company of practitioners who specialize in these forms of treatment, and seems to fill a place hitherto vacant in current medical literature.

THE ESSENTIAL OILS.

IN the preface to his book on *The Essential Oils*[5] Mr. HORACE FINNEMORE says that he will welcome suggestions for its improvement. This is the proper spirit in which to enter on a task of such magnitude, and we hope that the implied anticipation that a second edition may presently be called for will be fulfilled. As the experience the author has had of the essential oils of economic importance is both extensive and peculiar, it might have been expected that he would devote his attention exclusively to the matters on which he writes with authority; he has not been content thus to restrict his work, but has collated all the information he could find in order to produce an encyclopaedic volume. That course was justified, for a book of the kind was needed. The number of essential oils demanding attention in such a volume is very large, and any possible method of grouping them according to their characters would leave a large number unclassified; he was therefore wise in deciding to arrange them according to their botanical sources. A great number of the essential oils are not known as official or commercial articles, and the record of their constituents and properties is in many cases no more than the notes of a single observer. Among the rarer oils there are thus a number concerning which independent verification is lacking, and the statements about them have very different values. These all properly find a place in the volume, but discrimination has been used to indicate by the use of heavier type the products which are well authenticated and those of special importance. The author has bestowed much attention on the chemical relationships of the constituent substances which confer on the oils their economic value, and has indicated the methods by which these substances may be transformed into other desired products. That branch of the subject, closely connected as it is with synthetic production, has engaged much attention in recent years, and is destined to have a great influence on the industry in the future. The book contains copious data descriptive of the characters of the oils, the tests by which they may be identified, and the means by which substitution or sophistication may be detected. It contains a great store of information, which has thus been made readily accessible and suited to meet practical requirements.

WHAT IS SCIENCE?

AMIEL in his *Journal Intime* refers to science as "a lucid madness occupied in tabulating its own necessary hallucinations." This may be pardoned, coming as it does from a dreamer such as was the Genevese professor of moral philosophy; but it is somewhat of a shock to find Dr. HANS MUCH of Hamburg, the author of a series of volumes on modern biology, denying the status of science to spheres of research on living matter. His eleventh volume[6] gives us this impression. Its ten chapters are based on lectures delivered during a lecturing tour to Budapest, Pecs, Agram, Barcelona, Madrid, and Davos. Dr. Much is manifestly a disciple of Descartes, for he applies Cartesian doubt to everything except mathematical truth, and, as mathematical laws cannot be established in living matter, the facts discoverable in biology are, he thinks, insufficient to constitute a science. For example, bacteriology, for him, is not even knowledge, for the culture of bacteria is only a technique which can be learnt by anyone in a short time. He does not, however, attack the scientific aspirations of medical investigations and research, but only the conclusions drawn from them, more especially the attempt to formulate universal laws from a study of biology and disease. The ideas of the author in this respect are illustrated by a quaint diagram showing the process by which medicine progresses from a collection of clinical experiences to knowledge; from knowledge to technical dexterity; from this to what he will not call a science but a semblance of science, and finally to art. Beyond this medicine cannot go, since a solid wall intervenes between it and mathematical truth. Much of this reasoning occurs in the first chapter on "medicine as art or science." Dr. Much says it is neither, but a little of both. Other chapters are on biology and medicine, lipoids, immunity, colds, *plus* and *minus* sickness, and on antibodies of lipoid antigen. Two of the chapters are in French, the others in unusually clear and crisp German. The volume is entertainingly written.

NOTES ON BOOKS.

A TEXTBOOK that would appear to meet the requirements of public health officials and students in India is the *Manual of Hygiene and Public Health*,[7] by JAHAR LAL DAS, the officiating director of public health in the province of Bihar and Orissa. It has been written from the standpoint of Indian life, and consequently enters more fully than other textbooks on the subject into those conditions of town and village sanitation that are typical of tropical and semi-tropical climates. At the same time, this aspect of hygiene is only incidentally introduced into the various chapters, which have much the same character as those of textbooks for European readers. Such subjects, for example, as vital statistics, air, water, habitations, food, infectious diseases, meteorology, disposal of refuse and sewage, and industrial and school hygiene, are dealt with in accord with the general principles of hygiene and sanitation; and it is only the last three chapters that are specially applicable to Indian conditions, as their subjects—village sanitation and mass education, sanitation of fairs and festivals, and camp sanitation—indicate. To these, too, must be added the six appendixes on the duties of medical officers of health in the author's province and in Bengal, and on the model regulations and orders regarding food and the duties of district health officers and sanitary inspectors in these provinces. All the subjects are well illustrated, but the printing and paper are not of a high-class order. Lieut.-Colonel W. C. Ross provides a short introduction; and the best we can say for this manual on hygiene is that it is an excellent example of the earnest instructional work on hygiene which is being carried out by Indian writers for Indians, and promises rapid progress in the prevention of disease and in the improvement of the conditions of life among the Indian peoples.

Professor V. H. MOTTRAM has written an excellent book on *The Functions of the Body*,[8] which is described as an outline of physiology. That is a very good term for his work. It is by no means a book of the sort we are accustomed to associate with the teaching of physiology in elementary schools, which seems to do little more than give a few simple facts about the body apparently unrelated to each other. This book is tersely written, graphic, and illuminating; it surveys the whole field so that any intelligent reader would read it with pleasure and understanding, and not with the thought that he was being "talked down to." The author says the idea of the book came to him after noting that the average medical student was aghast at the size and the apparent tracklessness of the country surveyed in the current textbooks of physiology. His intent has been to give a bird's-eye view of the boundaries and important features as a preliminary to a more detailed survey. He has certainly done what he set out to do, and done it excellently.

Dr. H. H. BASHFORD'S pleasant volume, *The Corner of Harley Street*, first appeared anonymously, if our memory serves us, about sixteen years ago; but although its authorship soon became an open secret his name had not been disclosed on the title-page until the recent publication of a twelfth impression.[9] The book, we may recall, is cast in letter form, and purports to be some familiar correspondence of Peter Harding, M.D., whose outlook on life and letters may have owed something to Stephen Paget and Conan Doyle. Its continued popularity is not difficult to understand. The letters reveal their supposed writer as a cultivated man of 50, happy in his work and his home and his friends, with a strong vein of sentiment and a shrewd eye for the simpler issues of conduct and character. Dr. Harding, in short, is a story-book version of the kind of doctor many of us can match in real life, whom everyone looks up to and leans upon and likes. Even in 1927 a little sententiousness is forgiven in such a thoroughly good fellow.

In *Genius: Some Revaluations*[10] Dr. ARTHUR C. JACOBSON reviews in popular language the personal origins and characteristics of a number of well known persons of outstanding talent. He believes that the genius is a superman whose creative spirit resides, not in the primary self, but in a secondary personality which may be brought to the surface by drugs, drink, and disease. The author does not assert that geniuses are geniuses because they are insane, but argues that a genius is usually, if not always, of insane temperament, though his creative work reflects him at his best—that is, at his sanest. On the other hand, he considers that genius arises from abnormal, bad, and degenerate stocks, and is never found in the well bred, and, from a eugenic point of view, the best of the race. A number of eminent people, including Voltaire, Rousseau, Jane Austen, who, the author thinks, may have had tuberculosis, are mentioned to support the view that tuberculosis is "a quickener or inspirer of germinating or flowering faculties of extraordinary potentiality, which even without its influence would have marked their possessors as men of remarkable talent or moderated genius." The personal details about geniuses will interest many readers, but some may feel old-fashioned qualms about the good taste of a reference to a living man's relations.

PREPARATIONS AND APPLIANCES.

Acetyl-arsan.

IN a note on the pentavalent organic arsenicals entitled "Acetyl-arsan in syphilis" (BRITISH MEDICAL JOURNAL, January 15th, p. 111) the name "acetyl-arsan" was used to include oxy-acetyl-amino-phenyl-arsinic acid and its compounds. The Laboratoire des Produits "Usines du Rhone" has pointed out to us that acetyl-arsan is a proprietary name applied to a particular compound of the acid mentioned above—namely, the oxy-acetyl-amino-phenyl-arsenate of diethylamine, which was discovered and is sold by their firm. We regret the error. In our note reference was made to certain work by Laurent, and this was carried out with acetyl-arsan, but the rest of the note deals with oxy-acetyl-amino-phenyl-arsinic acid.

Kurchi Bark in Amœbic Dysentery.

Kurchi bark extract contains as its chief active principle the alkaloid conessine. This alkaloid occurs in various plants which for centuries have been held in high repute in the East as cures for dysentery. The introduction of emetine in 1912 was a very great advance in the treatment of amœbic dysentery, but emetine does not always cure the disease, and in recent years search has proceeded for alternative remedies. Stovarsol has been used extensively with considerable success, but kurchi bark extract deserves careful trial because it has the advantages of low toxicity, of not producing ocular complications, and of cheapness. Messrs. Burroughs Wellcome and Co. have put on sale tabloids of kurchi bark extract, each containing 5 grains.

Apparatus for Ultra-violet Radiation Treatment.

The attention which is now paid to phototherapy is reflected in the number of commercial pamphlets and catalogues which continue to reach us advertising apparatus for treatment by means of ultra-violet radiations. The recent developments do not seem to have produced anything revolutionary, but only more simplicity and variety of equipment—that is to say, the improvements have not been in the lamps themselves, but in the lamp-holders and methods of projection. Increasing ease of manipulation, of course, not to speak of cheapness, opens the way to the use of phototherapy by those who do not understand the effects of light treatment, though it should be said that in the literature which has reached us there is nothing to suggest that the apparatus may be used otherwise than by medical men or by trained nurses under medical supervision. A portable carbon-arc lamp for use on any voltage from 100 to 260, alternating or direct current, is made by the Apex Sun-Ray, Ltd. (Balfour House, Finsbury Pavement, London, E.C.). It is obviously a great advantage to the practitioner to be able to give treatment in the patients' rooms, and the spectrum of the lamp is said to cover the whole of the near ultra-violet region and to extend a useful distance into the far region. The lamp is easy to manipulate, and the manufacturers estimate the running cost at sixpence an hour. The Medical Supply Association, Ltd. (167-185, Gray's Inn Road, London, W.C.), has introduced a new arc-lamp rectifier whereby it is possible to work either a tungsten arc or a mercury vapour lamp from the alternating current. This is designed to save the much greater expense of installing a motor transformer or of making some modification in the system. The purchaser of any type of lamp for use on an alternating current supply will, therefore, by means of this rectifier, have to pay only a relatively small sum more for his equipment than would be the case if he had a direct current supply. We have also received the latest catalogue from Kelvin Bottomley and Baird, Ltd., who have opened new London showrooms at Imperial House, Regent Street. The catalogue describes the "K.B.B." apparatus (already noticed in these columns) for ultra-violet treatment. The special feature is a range of "sun lamps" and mercury vapour lamps designed to meet various conditions of treatment; some of them are on a floor stand, and others suspended from the ceiling. On a previous occasion also we have noticed a pamphlet entitled *Artificial Sunlight*, prepared by Watson and Sons (Electro-Medical), Ltd. (Parker Street, Kingsway, London, W.C.3). The edition for 1927 has been enlarged, and includes particulars of a considerable number of models of open arc lamps, with tungsten or carbon electrodes, and of mercury vapour lamps, as also a general description of the nature and action of ultra-violet radiation and the possibilities of the different sources.

HYGIENE OF SWIMMING BATHS.

A COMMITTEE of the Section of Laryngology, Otology, and Rhinology of the American Medical Association presented at the close of last year a report on the oto-rhinologic hygiene of swimming.[1] The numerous cases of otitis media, and also of infections of the external ear and accessory sinuses of the nose, which occur every year from swimming and bathing, lend importance to the recommendations of this committee; they take the form of a standard set of rules for sanitation and a notice for exhibition in swimming baths.

RULES FOR SANITATION AND SAFETY OF SWIMMING POOLS.

1. All swimming pools are to be maintained with a practical minimum amount of contamination. There shall be not more than 1,000 colonies per cubic centimetre of standard agar medium after incubating for twenty-four hours at 37° F. The *B. coli* content shall be such that gas is produced in not more than one and a half of standard lactic broth cultures after incubation for twenty-four hours with 1 c.cm. of water.
2. Water in the pool shall at all times of use be sufficiently transparent, under existing lighting conditions, that when the water surface is not excessively agitated by bathers, a person can stand at the side of the pool and see the bottom distinctly where the depth of water is 6 ft. or less.
3. Facilities for adequate protection of the pool water against unnecessary sputum contamination by bathers shall be provided.
4. All persons known to be or suspected of being affected with infectious diseases shall be excluded from the pool.
5. Contamination of the pool resulting from lack of personal cleanliness of bathers shall be maintained at a minimum.
6. Construction and appliances shall be such as to reduce to a practical minimum the danger of drowning and of injury to bathers from falls or collisions.
7. Dressing rooms, hallways, toilet rooms, shower rooms, and other places to which patrons of a bath house have access shall be kept clean and well ventilated at all times.
8. Bathing suits and towels, when distributed to bathers by the pool management, shall be clean and free from excessive bacterial contamination.
9. The management of the pool shall have printed and posted in conspicuous places about the establishment notices briefly informing patrons of the requirements to which they are subject in the maintenance of a safe and sanitary pool. A form of notice is suggested to pool operators; it should be so placed that all bathers cannot fail to read it before entering the pool.

The approved form of notice to be exhibited in swimming baths (referred to in Rule 9 above) is as follows:

Form of Notice.

Warning: Persons with colds, head infections, "running nose or ears," catarrh, are warned that swimming, diving, etc., tend to force the infection into the sinuses or ears, and result in serious if not fatal complications.

1. All bathers shall use shower baths, including soap, if necessary, before entering the plunge. (The plunge is not intended as a bath tub.)
2. Bathers who have been outside the bath house or plunge enclosure shall not re-enter without passing through a foot-bath and using a shower.
3. Bathers shall be forbidden to wear private bathing suits that are not properly laundered; light coloured or undyed wool is suggested.
4. Women shall wear caps while in the plunge.
5. Persons not dressed for bathing shall not be allowed on walks surrounding plunge, and bathers shall not be allowed in places provided for spectators.
6. No person suffering from a fever, cold, cough, or inflamed eyes shall be allowed the use of the plunge. (These disorders may be transmitted to others.)
7. No person with sores or other evidence of skin disease, or who is wearing a bandage of any kind, shall be allowed the use of the plunge. (A bandage may conceal a source of infection.)
8. Spitting in, or in any other way contaminating, the plunge, and spitting on floors, runway, aisles, or dressing rooms shall be prohibited.
9. Public combs or brushes shall not be furnished, and such articles left by bathers shall be permanently removed.
10. Eating within the plunge enclosure shall be prohibited.
11. Bringing or throwing into the plunge any objects that may in any way carry contamination, endanger safety of bathers, or produce unsightliness shall be prohibited.

SPAHLINGER TREATMENT.

REPORT FROM NEW SOUTH WALES.

THE Premier of New South Wales last November laid on the table of the Legislative Assembly a report on M. Spahlinger's treatment of tuberculosis by Dr. McIntyre Sinclair, who in August, 1925, visited Geneva and spent several weeks there inspecting the laboratory at Carouge and examining patients under treatment or previously treated. The cases selected were of severe type or had failed to respond to other methods.

As Dr. Sinclair was formerly Medical Superintendent of the Queen Victoria Homes for Consumption, New South Wales, he was in a good position to judge the clinical results; he examined over thirty cases of more or less advanced type. In forming his opinion he was able to study the histories, along with temperature charts, and skiagrams when available. He discussed the serum therapeutics of tuberculosis with members of the Pasteur Institute, Paris, with Dr. S. R. Douglas of the National Medical Research Institute, Hampstead, with Mr. Alexander Fleming of the vaccine laboratories, St. Mary's Hospital, London, and with Professor Carl Browning of Glasgow. *He seems, therefore, fully justified in claiming that he* was careful to ascertain the clinical facts, and to obtain opinions on the theoretical considerations that arise.

Dr. Sinclair's report falls into two parts: the first deals with the therapeutic value of M. Spahlinger's vaccine and serums, the second with the policy to be followed in making an independent test of their practical value.

Vaccine and Serums.

On the vaccine Dr. Sinclair makes the following observations:

> The "vaccine" remedy is applied to exploit the active immunity responses of the human organism, while the "serum" is used as a passive immunization agent on similar principles to the well known diphtheria antitoxin. Spahlinger uses his "vaccine" in apyrexial or slightly pyrexial cases, and also in cases which have already been improved by the "serum," but in which he desires to confer a more lasting immunity. I examined several cases treated or under treatment with Spahlinger's "vaccine," and soon came to the conclusion that its effects, clinically and otherwise, are practically identical with those produced by the tuberculin "bacillen emulsion" of Koch, a remedy with which some of us in New South Wales are quite familiar, and which I have been using in my own practice for at least twenty years. Spahlinger's "vaccine" is, without doubt, a valuable remedy, but it does not, in my opinion, teach us anything we did not know before.

Of the serum Dr. Sinclair writes:

> [it] certainly makes a new claim on medical science, inasmuch as the production of an "antitoxic serum" for tuberculosis (on similar lines to the antidiphtheritic serum for diphtheria) has, up till now, baffled the ingenuity of all scientific workers on the subject. In the production of an antitoxic serum, Spahlinger, in my opinion, has succeeded where others have failed. It is true that the serum has its proportion of failures, that its administration is in many cases not unattended by discomfort and even occasional danger; but taken all over it appears to have many remarkable successes in cases of tuberculosis, and even in cases where every other known method of treatment has failed. In my opinion it marks a distinct step forward in the treatment of the disease.

On this head his conclusion is that

> "Spahlinger has discovered a remedy of considerable value, and that every reasonable endeavour should be made to obtain the serum for use in certain types of tubercular disease. It appears to me to be of particular value in tuberculosis of the acute toxaemic type, in cases with continuous high temperatures which have failed to respond to open-air or other methods of treatment, and in cases of pulmonary tuberculosis with gastro-intestinal complications. I saw cases of those types which had apparently made good recoveries—cases which from their histories would probably have died but for the use of the serum."

The Need for Extended Test: Personal Difficulties.

Holding these views, Dr. Sinclair is of opinion that a case had been made out for an independent test on a large scale, and advises his Government to co-operate with the British Government in making a grant to M. Spahlinger to defray the cost of making the material. He is, however, like others before him, baffled by the attitude M. Spahlinger has assumed during the various negotiations between him, the Ministry of Health, the British Red Cross Society, and others.

In the first place, Dr. Sinclair notes that the remedy is secret, and observes that the "continued preservation of a secret remedy likely to be of use to suffering humanity is totally contrary to the ethical code of the medical profession. Such a secret remedy is always looked upon with suspicion, and history proves that this view is generally correct." In this connexion Dr. Sinclair mentions an incident which is perhaps not generally known—namely, that Professor Calmette of the Pasteur Institute, Paris, in September, 1925, had made a personal offer to M. Spahlinger "to test out his serum for its antitoxic value, and that Spahlinger had declined to avail himself of the offer." Dr. Sinclair notes that

> "It is true that if Spahlinger's serum is really all that is claimed for it, then it rather upsets Calmette's teaching on the subject of antitubercle sera. Spahlinger apparently distrusts Calmette. But there are surely other leading bacteriologists who could serve equally well. *The refusal to submit his serum to independent* scientific tests is one for which Spahlinger is himself responsible, and if the refusal leads to suspicion and scepticism, it seems to me it is not difficult to allocate the blame."

While in Switzerland Dr. Sinclair received a telegram stating that the Government of New South Wales contemplated sending a bacteriologist and four patients to Geneva if M. Spahlinger would consent to treat them. This request M. Spahlinger refused, and in an interview with Dr. Sinclair mentioned shortage of serum and financial difficulties. In order to bring the matter to an issue Dr. Sinclair asked M. Spahlinger to suggest a sum which might be offered to him in order that he might treat these cases, but he declined to do so. Subsequently the Agents-General for New South Wales negotiated with M. Spahlinger, but no further progress could be made. M. Spahlinger informed Dr. Sinclair that he would never exploit his remedies and did not wish to make any money out of his discoveries. While admiring this altruistic spirit Dr. Sinclair suggests that all M. Spahlinger has to do is to publish his formula to the scientific world, or to permit the preparation of the remedies under Government supervision, comparable with the method followed in the case of insulin. Failing this Dr. Sinclair thinks it would be better to have the remedies distributed by a reputable commercial house than not at all. One firm of world-wide commercial chemists did, Dr. Sinclair adds, make M. Spahlinger an offer which would have made him rich. The proposed agreement was on business lines, and M. Spahlinger would have had to show the firm's scientific experts how to produce the serum so that they could commercially meet the demand. M. Spahlinger declined this offer, and Dr. Sinclair adds:

> "So far as I could ascertain from M. Spahlinger and his friends, he is willing to accept a large sum of money to free him from his liabilities, and you then trust him to deliver the goods. I think that is putting it fairly in plain English. I cannot be expected to recommend this course to any responsible Government. To use Sir Neville Howse's expressive words, it would be 'buying a pig in a poke.' Although Sir Neville Howse and I hold opposite views on the value of the serum, we are agreed on that point."

The report notes that the British Government's offer still stands good, to test out the serum under its auspices in London provided M. Spahlinger will submit the remedy for an extensive trial. As will be seen from Mr. Neville Chamberlain's reply in the House of Commons published last week (p. 359), this offer is still open.

Dr. Sinclair thinks that if M. Spahlinger cannot produce the material necessary owing to shortage of funds it would be fair to go a step further and give him the financial assistance necessary to produce the required quantity of serum. How much money would be necessary for this purpose it would be for M. Spahlinger to indicate, and Dr. Sinclair concludes by advising his Government to offer the British Government a proportion of the grant for the purpose.

MENTAL DISORDER IN RELATION TO EUGENICS.

GALTON LECTURE BY DR. A. F. TREDGOLD.

AT the annual dinner of the Eugenics Education Society, commemorating the birthday of Sir Francis Galton, on February 16th, the Galton lecture was delivered by Dr. A. F. TREDGOLD, whose subject was "Mental disorder in relation to eugenics."

Dr. Tredgold said that the evolutionary change which had taken place in man since his emergence from the anthropoid apes had been mainly in the sphere of mind, and if he was to undergo any further evolution—which was certainly possible—there could be little doubt that it would be in the same direction. Progressive evolution, however, was dependent upon vitality and mental capacity, hence the importance of mental disease from the aspect of eugenics. A distinction should be made between mental disease and eccentricity. Many persons were to be found whose mode of thought and behaviour differed very much from that of the majority. These persons were regarded as eccentric, but this did not mean that they were inefficient or were lacking in adaptation; on the contrary, they were often pioneers of thought and most valuable members of the community. Mental disease might be said to take one of three forms: defect, disorder, and decay—all of them due to the failure of the organism to adapt itself to its environment. With certain exceptions, all these three forms were but different manifestations of one and the same underlying cause. The great majority were the result of inheritance. In insanity and mental breakdown undoubtedly environmental factors played a great part, but even here it was generally accepted that the main cause was constitutional rather than environmental. In shell-shock cases, for instance, the real cause of breakdown was mental stress, and in most of the sufferers a definite predisposition to this breakdown was present. Some of them were never near the firing line, nor had they seen or heard an exploding shell.

The inheritance, however, was not of the disease itself, but of the neuropathic diathesis, which diathesis was due to an impairment, or devitalization, of the germ cell. This impairment varied in degree in different cells, and as it was influenced by the condition of the second or combining cell, as well as by the environment, the results upon the offspring differed very greatly. Dr. Tredgold stressed this point that there was no inheritance of mental defect or insanity as such, or of any quality as it existed in the individual. While every organ and tissue of the body was represented in the germ plasm from which it was derived, such representation was not in the form of organ or tissue, but of determinants or directive forces. What was inherited was a tendency for development to proceed in certain particular directions and up to a certain limit. The result of such inheritance was, in some cases, mental deficiency, in others various forms of insanity or dementia, and in yet others the individual might go through life apparently normal, though still a "carrier" of the impairment, which might reveal itself in mental disease in a subsequent generation. During the past ten or twelve years a good many attempts had been made to show that mental disease or defect was a Mendelian unit, transmitted in accordance with Mendelian laws, but these attempts had failed. What seemed to be clear was that if with the impaired cell there was combined a cell similarly impaired then the developmental potentiality of the embryo was still further reduced, but that if the combining cell was healthy such reduction would be less marked, and the individual might show a normal mentality, though he or she was always liable to mental breakdown when exposed to physical or mental stresses, or even to changes incident to any of the physiological periods of life, such as the climacteric, and in many cases such breakdown was the beginning of a steadily progressive dementia. On the other hand, given the healthy combining cell together with favourable surroundings, particularly in early life, and the impairment might be neutralized and even bred out. Mental disease in the community was kept alive by "carriers"—that is to say, people who might themselves appear to be normal, inasmuch as the disordered tendency was very slight, and they had not been exposed to any conditions which would precipitate a breakdown. But the tendency was there, and under certain conditions their offspring might again have the taint.

In assessing the ravages of mental disease, the lecturer found himself quite unable to place on the asset side the contributions of genius. He found no evidence of close association between genius and insanity. No doubt some men of genius had been of poor physical constitution and prone to ill health, and others had been eccentric and possessed a delicately balanced brain. But he had searched in vain for any close correlation between the two things, and the great majority of men of genius struck him as having been remarkably sane. On the other hand, there was abundant evidence that mental disease was closely associated with social inefficiency and retrogression. The statistics furnished to the Royal Commission of 1904 showed that in every 1,000 of the population there were four mental defectives and nearly as many insane. This corresponded at the present time to a total of 174,000 defectives and 134,000 lunatics, and no doubt these figures underestimated the real incidence. Probably over 1 per cent., perhaps nearer 2 per cent., of the population were in some way affected. In addition to these, an even larger number of persons, while not certifiable, suffered from such disabling conditions as neurasthenia, hysteria, epilepsy, and borderland states. According to a recent report of the Board of Education there were no fewer than 600,000 mentally backward children in the country. Serious as was the damage done by mental disease to the present generation, it was probable that that inflicted upon the race was even greater, for, by the mating of affected persons or of carriers with the healthy, the impairment was greatly disseminated. If the mating of neuropaths could be rigidly restricted to those similarly affected, the disease would work out its own elimination in eventual sterility. This factor had probably been at work in the reduction of the incidence of other diseases; the decline in tuberculosis, for example, might be due to the gradual eradication of the susceptible rather than to preventive medicine. The statement had been made that no families were free from the neuropathic taint, but with this he did not agree, and he considered that the danger to the race lay in the contamination of sound and healthy stocks by those predisposed to the disease.

There could be no question, Dr. Tredgold said, that one thing urgently needed was the prevention of propagation of those persons who suffered from diseases which were due to inheritance. As for the merits of sterilization and segregation, after consideration of all the problems involved, he had come to the conclusion that the advantages of segregation outweighed those of sterilization, but even were it possible to prevent, by one or other of these methods, propagation by every person now suffering from insanity or mental defect, there would still be a long way to go before mental disease could be eradicated. The mating of carriers with the healthy was the greatest danger to the race. Every change in social conditions and every advance in evolution brought in its train certain inimical agencies which impaired the germ cells of those individuals who were unfit to continue the march. The great need was to prevent such persons contaminating the healthy stocks, and there was real danger of the dragging of sound stocks into the vortex of disease. His own feeling was that there was only one way in which it could be hoped to stem degeneracy and assist racial progress, and that was by an intensive educational campaign for the development throughout the nation of the eugenic ideal—an ideal which should not merely be given intellectual adherence, but should have the quality of a sentiment and emotion, like the religious and aesthetic sentiments which had been so widely diffused and had achieved so much.

The vote of thanks to the lecturer was proposed and seconded respectively by Professor E. W. MACBRIDE and Sir FREDERICK WILLIS; Major LEONARD DARWIN, who presided, added a few words, in which he advocated the Mendelian theory of heredity, which he thought offered the only rational explanation of many of the facts.

MEDICAL RESEARCH COUNCIL.

ANNUAL REPORT.

I.

THE annual report of the Medical Research Council for the year 1925-26 is arranged on what we may now call its usual plan, which from the experience of past years is already familiar to our readers. Itself a summary of many and diverse investigations it is a difficult document to analyse, and we must content ourselves with giving a brief outline of some of the work in its various sections.

Although outside the work of the Council itself, attention may be drawn to a passage in the report of the Committee of the Privy Council for Medical Research, wherein Lord Balfour speaks with confidence and hope of the way in which the new Committee of Civil Research has already, in its early beginnings, co-operated with the Medical Research Council in the work of bringing science into its fullest application to the practical problems of administration and human need; and also to the fact that at the recent Imperial Conference it was for the first time decided that among the primary subjects for discussion should be the problem of organization of research work and the better application of its results to the full development of the natural resources in different parts of the Empire. Representatives of the Medical Research Council took part in these discussions as members of the Special Research Subcommittee.

ACADEMIC RESEARCH AND PRACTICAL APPLICATIONS.

In the introduction to the report the Council explains the principles that guide it, and lays stress on the need for allowing complete freedom to individual workers to advance along whatever lines seem most advantageous to them in the pursuit of their object; and it points out how frequently the key to any particular problem is obtained in most unexpected quarters, and how often what would appear to be an observation of purely academic interest may prove of immense value to practical medical science. As illustrations of this the stories of a few investigations are related in fuller detail than is possible in the general body of the report. Histamine, isolated by Dr. Dale with Dr. Barger and Dr. Laidlaw from ergot, and shown by them to exist in the wall of the human intestine, was at first thought something of a curiosity. During the war, in the investigations into the phenomena of fatal shock following on extensive wounds it was apparent that the symptoms were exactly comparable to those produced by histamine, and Dr. Dale and Dr. Laidlaw, pursuing their investigations, were led to what are now classical observations upon the capillary circulation, and the new knowledge thus gained helped greatly towards the practical methods of prevention that were eventually developed. Further study now suggests that the phenomena observed in shock are merely the exaggeration of the normal physiological mechanism for the control of the capillary circulation, and much evidence in this direction is coming from the studies of Sir Thomas Lewis and his colleagues upon the circulation of the skin, some of which are briefly reviewed in this report.

The part played by the chemical study of the sterols in the elucidation of the nature of the action of the vitamins is another of the illustrations chosen. Recently it has been shown that the vitamin in which cod-liver oil is peculiarly rich, and which is of such value in the treatment of rickets, is formed when cholesterol and other sterols are exposed to rays of ultra-violet light, and it now appears that in reality the true parent of the vitamin is not actually cholesterol but some closely related substance inseparable by ordinary methods of purification. Here the knowledge of the structure of the sterol group acquired by purely academic chemical studies promises again to solve our problem; Professor Windhaus of Göttingen, with his unrivalled knowledge of this aspect of the subject, has co-operated most generously with Dr. Rosenheim and Mr. Webster of the National Institute, as also has Professor Heilbron of Liverpool, whose own independent research on the subject was noted in our columns a fortnight ago (p. 296). With this happy co-operation of academic study and clinical observation the authors of the report are able to express the hope that it may soon be possible to express in the terms of exact science the relation between the effects of natural foods and substances like cod-liver oil, and of exposure to clear sunlight in clean air in producing healthy development of the body with straight limbs and sound teeth.

Other examples are found in the work on insulin, diet in relation to the formation of teeth and the prevention of decay, and studies of filter-passing viruses; these will be referred to briefly in their sections.

PROBLEMS OF CHILD LIFE.

Dr. F. J. Browne has continued his investigations on neo-natal deaths, and has shown that infection may occur from the inhalation of liquor amnii and its contents; he has also found evidence that brings the accidental haemorrhages into the category of the toxaemias of pregnancy. A combined clinical and chemical study of a series of cases of albuminuria, toxaemia, and eclampsia with a control series of normal pregnancies has been undertaken by Dr. Cruikshank and his colleagues in Glasgow. Mrs. M. Forest-Smith's report on the incidence and causation of rheumatism in children, which includes the results obtained at St. Thomas's Hospital, Great Ormond Street, and Glasgow, and to which reference has been made in the previous report, has been concluded, and is now in the press. Dr. Lucy Wills and Dr. D. Paterson have continued their work on gastric acidity and calcium absorption; a detailed study of the gastric secretion, including chloride estimations, has been conducted. Similar investigations have been made by Dr. L. Parsons confirming his previous conclusion that in general there is no defect of absorption in infantile atrophy.

HUMAN NUTRITION.

At the Lister Institute Dr. S. S. Zilva has continued his chemical study of vitamin C, particularly with regard to the relationship between the antiscorbutic activity and the reducing substances present. Miss M. Soames and Miss Leigh-Clare have estimated the relative potency of different Norwegian cod-liver oils in vitamin A content; parallel experiments were made to determine their vitamin D content. The vitamin A and D potencies were not parallel, although in general for both vitamins the order of merit of the oils was the same. Professor Drummond and his colleagues at University College have continued their investigations on the nature of the vitamin in cod-liver oil with the object of preparing on a large scale the unsaponifiable fraction; valuable help has been given here by Mr. F. H. Carr of British Drug Houses, Ltd., who has provided suitable plant. Reasonably large yields have already been obtained. With Mr. H. J. Channon, Professor Drummond has also studied some of the substances that accompany the vitamin in the unsaponifiable fraction of some fish-liver oils; it has been shown that squalene may constitute 80 per cent. of the total fat in some fish livers, and that it is absorbed by the mammalian intestine; Professor Heilbron's work has shown that on the chemical side squalene may be regarded as a precursor of cholesterol, and Mr. Channon, who has already proved that the animal organism can synthesize cholesterol from an unknown precursor, has now found an increase in the cholesterol of the livers of rats fed on squalene. Professor Drummond's work on the mode of action of vitamin B suggests that there is an essential relationship between the results of vitamin B deficiency and those of starvation, and that vitamin B acts mainly as an essential stimulator of appetite and food consumption. Miss Reader, in the same laboratory, has shown that whereas young animals often fail to grow if the diet consists too largely of protein, normal growth may be obtained if the vitamin B in the diet be increased in proportion to the increase in the protein. These studies have also shown that the excretion of large quantities of nitrogenous end-products has no harmful effect on the kidneys

provided that there is no deficiency of vitamin B; extensive damage to these organs, however, may occur, whatever the composition of the diet, if there is a deficiency of vitamin B.

DENTAL DISEASE.

Special attention is drawn by the Council this year to the results of Mrs. Mellanby's work on the relationship of vitamin D deficiency and the formation of teeth and the prevention of decay. Mrs. Mellanby long ago ascertained that deficiency of vitamin D in an otherwise complete diet during the period of dentition leads to imperfect development of the jaws and teeth in animals, showing itself in an absence or imperfection of the enamel and a corresponding defect in the secondary dentine. To the obvious suggestion that such teeth might be expected to be affected more easily by caries, it was at once objected that caries appears quite commonly in teeth with good enamel; but Mrs. Mellanby, by the microscopical examination of 1,000 teeth, has shown that naked-eye examination is insufficient to reveal defect in the finer structure of the enamel, and records that although only 3 per cent. of these teeth would have been condemned by ordinary standards as malformed, no less than 80 per cent. were structurally imperfect. Of the badly formed teeth, 95 per cent. showed evidence of decay, whilst of the sound teeth only 23 per cent. showed decay. With Dr. C. L. Pattison Mrs. Mellanby has also studied the dietetic control of dental caries; in a series of 75 children it was found that with a diet rich in vitamin D and with relatively little oatmeal, the average number of teeth showing an extension of caries was 1.77; when the diet contained less vitamin and more cereal the number was 5.78. These results with others already obtained show clearly that the dietetic conditions which produce good or badly formed teeth in dogs similarly influence the resistance to caries in fully erupted teeth of children.

DISORDERS OF THE CARDIO-VASCULAR SYSTEM.

Sir Thomas Lewis has continued his studies of the physiology and pathology of the cutaneous blood vessels. The regulation of the blood flow in the capillaries is found to be effected in part by the products of local change, an excessive supply of blood due to the opening of the small arteries being balanced by a diminution in the minute capillaries as these products are diluted and removed. Freezing damages the cells proper to the skin, liberating chemical substances to act on the vessel walls. Cold slows the skin blood flow, but also lessens the local oxygen exchange and the skin remains red. The redness due to warmth is not a direct temperature effect, but is due to an excess of chemical products in the tissue spaces producing dilatation of the capillary vessels. It is suggested that frostbite and burns in their early stages should be treated by temporary obstruction of the circulation, since a free circulation of fluid aggravates the original damage.

Dr. Drury and his colleagues have gone on with their work on conduction in the auricle of the heart, and have devised special methods giving a much more accurate estimate of the changes that occur in the electrical charge upon the muscle fibre when it passes into activity than has previously been possible; and they consider that the method of measuring the rate of conduction used by Burdon-Sanderson and Page should be abandoned. Their work also shows that much previous work on the refractory period in heart muscle needs careful revision. The effects of ouabain in auricular fibrillation have also been studied.

Dr. J. C. Bramwell and Dr. Sylvia Hickson have investigated the mode of production of "Korotkow sounds"; some of these appear to be true records of the movements of the arterial wall, others are due to the resonance of the air in the recording system.

At the National Institute for Medical Research Dr. Best and Dr. Dale, examining a liver extract advocated for the reduction of excessive blood pressure in man, found present in it two vaso-dilator principles resembling choline and histamine in their mode of action. Dr. Dudley and Mr. Thorpe succeeded in isolating these two active principles from the liver substance, with the result that they were actually shown to be choline and histamine. It was then ascertained that extracts from lung were also particularly rich in substances having an action of the histamine type. It is already clear that a widely spread vaso-dilator substance, known to be yielded by almost all the tissues of the body, will probably prove to be actually histamine itself.

MENTAL DISORDERS.

Miss L. P. Fildes, working at Cambridge, has completed her inquiry into the possible value of tests involving moral judgement in the diagnosis of moral defect; her conclusion is that tests of this kind are of little or no value.

Dr. F. E. Reynolds has collaborated with Dr. A. Logan Turner in Edinburgh in an investigation into the paths of infection of the brain, meninges, and venous sinuses from local foci of infection, and finds that in three specially studied cases infection spread by the venous blood stream in two when the face and the sphenoidal and ethmoidal air sinuses were the primary focus; in the third the infection spread from the nasal cavity by way of the olfactory perineural lymph sheaths.

GLANDS OF INTERNAL SECRETION.

Dr. Gardiner-Hill, Dr. Forest-Smith and Dr. Jones, at St. Thomas's Hospital, have established the fact that pituitary extract taken by the mouth has a definite effect, the influence being particularly noticeable on carbohydrate metabolism. Their observations have been directed chiefly towards a more efficient treatment of obscure endocrine disorders, and some very encouraging results have been obtained.

Mr. C. W. Bellerby, with Dr. A. S. Parker, at University College, has studied the internal secretion of the ovary; they find that the oestrus-producing hormone can be extracted from the stroma as well as from the ovarian follicle. Injection of the extract in the early stages of pregnancy invariably causes oestrus and terminates the pregnancy.

Professor Korenchevsky, at the Lister Institute, has continued his work on the sexual glands. Protein and lipoid extracts of testes and prostates have been prepared; some of the protein fractions were found to increase nitrogenous metabolism by one-third; no fraction exerted any influence on the growth of normal sexual organs or on the regeneration of atrophied sexual organs in the rat.

DIABETES AND INSULIN.

Dr. C. H. Best of Toronto and Dr. J. P. Hoet of Louvain, working as guests at the National Institute for Medical Research, have renewed the investigation of the fate of glucose which disappears from the circulation under the action of insulin. Work by Dr. Best on artificially perfused limbs showed that the muscles were the chief site of the disappearance; further combined investigations indicated that the phosphates left the blood concurrently with the disappearance of glucose from the blood, and that this was not accompanied by storage of phosphoric esters in the muscles when a large amount of the missing glucose was found in the form of glycogen. Later studies showed that under all conditions of glucose supply in relation to the dose of insulin the sum of the glucose accounted for as burnt, together with that found stored in the muscles as glycogen, was regularly equal to the total quantity of glucose disappearing from the system. They suggest that insulin not only promotes the storage of glucose as glycogen, but also restrains the new formation of carbohydrate in the liver; the action of insulin in excessive doses would thus be merely an exaggeration of that which it exerts in physiological and therapeutic amounts. Arising out of this work on insulin, certain phenomena were observed with an important bearing on the nature of rigor mortis, and, by implication, on the chemical changes which result in muscular contraction. In animals dying from an overdose of insulin there is practically complete exhaustion of muscle glycogen, and these glycogen-free muscles enter into rigor with their reaction still alkaline. The evidence suggests that the disappearance and re-formation of lactacidogen are as important factors in contraction and relaxation as are the appearance and removal of lactic acid.

(To be continued.)

SATURDAY, FEBRUARY 26TH, 1927.

PUZZLES OF LIFE ASSURANCE EXAMINATION.

THE address by Professor Lovell Gulland which appears in our columns this week (p. 363) deals with three of the great puzzles of life assurance examination—high blood pressure, albuminuria, and glycosuria. It speaks with the voice of experience, and will repay the close attention of those who are interested in this bypath of medical practice. Of the three faults, high blood pressure is comparatively a newcomer to the list of insurance riddles, and a very awkward customer it is proving to be. The two others have been offering themselves for solution in different guises for years, but still remain capable of flooring the best of us upon occasion. If to these three we add phthisis and syphilis we shall have completed the tally of the standard difficulties encountered in this branch of our art. There are plenty of posers set to the examiner for life assurance which fall outside these boundaries, but no others occur to us which present themselves at once so often and so abundantly provided with imponderables.

Of all these five, save one, it may be said that we have come to treat them with growing leniency as we have learnt to grade their degrees and varieties. The one exception is high blood pressure. Here, it must be confessed, time and experience have but served to accent the significance of the finding. High blood pressure may, indeed, be but a passing event, the expression perhaps of a vasomotor storm due to worry or overwork, or even the panic fear of a medical examination; or perhaps it is the signal of some fault of chemistry born of too much food or too much drink, or some other manageable external agency. But it is certain that the more a man's regular established blood pressure exceeds the modest scale allotted to youth, the less, proportionately, is his prospect of long living.

What is a high blood pressure? The question is easier asked than answered, but informed opinion will not quarrel with Professor Gulland when he says that "the normal limit ranges between 110 and 150, with the proviso that, other things being equal, young people tend to have a pressure nearer the lower figure, old people nearer the higher." There is, however, a wide range of pressures which all would agree in calling high without being able to agree upon the assessment of their significance. This disability is inherent in the quality of the problem. High blood pressure is either a cause or a consequence of arteriosclerosis—that is to say, it is attended by very widely spread lesions of the vascular system. The extent of the threat to life in any given case will be settled to a large extent by the precise points of impact of these lesions—that is, by their geographical caprice. And so it comes that one man will live for years on good terms with his blood pressure, although it is of a height which seems capable of putting another into immediate jeopardy of his life; the distinction between them, could we but see it, being perhaps no more than this, that the atheroma which is common to them both occurs harmlessly along the highway of the aorta of the first, while in the second it has barred the coronary artery. Such are the abiding uncertainties of high blood pressure.

Albuminuria is being treated by insurance medical examiners with increasing leniency. This does not imply any random disregard of a finding which may be ominous, but rather that the presumption, as regards proposers for life assurance, is in favour of their being healthy in the mass. Accordingly albuminuria in the apparently healthy, provided they wear none of the livery of chronic renal disease such as an enlarged heart, is regarded with a good deal of composure. Especially is this the case in youth; for after middle age the presumption begins to be against the good health of a kidney which secretes an albuminous urine, and the burden of proof that this departure is of no importance rests now upon the owner of it. It is here that, according to some, the modern tests of renal function may be invoked to save the situation and permit justice to be done. Others, like Professor Gulland, are unconvinced. "I am not greatly impressed," says he, "by the value of any of these tests of renal efficiency. They generally merely confirm by an arithmetical figure the fact that kidneys are not efficient when we know already for other reasons that this is the case. Sometimes they actually tend to lead us astray." So the matter stands at present — *sub judice* for the judicially minded, *judicata* for those who incline by nature to short cuts and novelties, about whom we shall have something to say presently.

Glycosuria, like albuminuria, has established its claim for more lenient treatment than was accorded to it twenty years ago, not so much perhaps because diabetes is less fatal as that we are better able to say what glycosurias are diabetic. Certainly we are in debt to those whose analyses of sugar tolerance and blood sugar have put us in the way of classifying this motley company; but whether all is now as plain sailing as some pilots would have us believe is a question that still waits upon the future. Professor Gulland is again among the doubters. "We are told," he says, "by some of the metabolic experts that renal glycosuria [that is, the glycosuria of those whose blood sugar never exceeds the normal range] is of no importance, and that these cases ought to be taken at ordinary rates. I always put on an extra, and shall continue to do so. One reason for this is that I have seen cases of renal glycosuria pass into true diabetes. Another is that the differentiation of these cases is so recent an affair that the life-histories of very few cases have been completely studied, and we really do not know what becomes of them in the long run."

These reactionary—or should we say subversive?—sentiments lead us to recur, for a moment in conclusion, to the saying of Hughlings Jackson quoted with veiled approval by Dr. Kinnier Wilson in a recent issue (p. 224), to the effect that it takes twenty-five years for new conceptions of disease to penetrate the mind of the medical profession. Hasty generalizations such as those to which Professor Gulland takes exception are the laggard's warrant for hurrying slowly. Whether in medicine, or fashions, or politics, we seem fated to move in jerks and exaggerations, like the departing traveller in a tube-railway carriage. He goes too fast and too far, and checks and staggers and plunges, yet makes the doorway at last. And so it is with new methods and ideas. The claims that are made for them may be too large, or made too early, and yet the advance may be real enough. It

behoves us, then, to be patient, and to cherish a subdued hopefulness of these new things; and if, as we do not expect, it should in time appear that renal glycosuria is after all none other than our old acquaintance diabetes, in a beard, so to speak—why, it is the penalty of growing older in medicine that we are often in black for lost illusions, so our wardrobes will be equal to the occasion.

THE EXPERIMENTAL METHOD IN THE HEALING ART.

IT cannot be gainsaid that the ultimate object of medicine is the prevention or cure of disease. In past ages disease was associated, in the minds of men, with malevolent spirits, and treatment consisted of an endeavour to appease these by prayers and incantations. In the Middle Ages treatment was largely based on the doctrine of signatures. This had it that an all-benevolent Deity had placed His stamp on plants so as to indicate to the physician their use in treatment; hence the names of lungwort and liverwort, while lunacy was treated with silver because this metal was dedicated to the moon.

The School of Spagirists, which reached its climax in the time of Paracelsus, insisted on the mystical virtues of antimony, arsenic, and silver. It is not surprising, then, that homoeopathy, which was a reaction against excessive drug-taking, found ready disciples in the profession. Disease was regarded as a perverted spiritual force; plants also were thought to have a spiritual power which could be liberated by dilution, and the greater the dilution the greater the power. The nineteenth century was characterized by a period of therapeutic nihilism which, starting in Vienna, spread over Europe, its object being, as we see now, to destroy and bury the accumulated refuse of the centuries. Until a rational diagnosis had developed from scientific and physical methods real treatment could not exist. All these mystical and subjective speculations in past centuries have left us little or nothing for the good of humanity or for the treatment of disease.

All precise knowledge of treatment is based upon controlled experiments on animals and man, and the last half-century has done more for the alleviation of pain and suffering than all the centuries preceding it. Huxley, who saw further than most men, enunciated this principle more than a quarter of a century ago when he wrote: "The search for the explanation of diseased states in modified cell life; the discovery of the important part played by parasitic organisms in the etiology of disease; the elucidation of the action of medicaments by the methods and the data of experimental physiology; appear to me to be the greatest steps which have ever been made towards the establishment of medicine on a scientific basis."

All who follow medicine are practically unanimous in recognizing, not only what they owe to the experimental method, but that advance in medicine, as in all other sciences, can only come from experiment and observation. Moreover, all fundamental advances in treatment in the last quarter of a century have originated, directly or indirectly, from experiments on animals, and no new drugs have been applied to treatment during that period except such as have been introduced through the medium of the laboratories. The treatment of endocrine diseases is even now being revolutionized by laboratory experiments. Thus insulin, which has done so much to help our diabetics, is not necessarily the end-point in treatment. A derivative of agmatin, a body obtained from the amino-acid arginin, has been found to lower the blood sugar like insulin, but it acts by the mouth; how far this or allied drugs may replace insulin has yet to be determined by further experiments.

Nevertheless, history shows that all great progressive movements meet with opposition, which generally makes up with noise what it lacks in reason. A majority of the council of the Royal Society for the Prevention of Cruelty to Animals are using their position and influence to petition Parliament to forbid all experiments on dogs. The passage into law of such a bill would seriously curtail medical research in this country. Scientific men are apt to be absorbed in their work and unmindful of the clamour around them; but the present Dogs Bill, rightly understood, is in reality an attack on the public and on the practice of medicine. No life is better adapted to bring out the higher qualities in man than that which demands continuous service on the sick; and infinite patience and sympathy with pain and suffering are essential in those who follow the healing art. We yield to none in our affection for the dog, and desire that everything should be done for its proper protection, but we have no sympathy with the present misguided effort on the part of the R.S.P.C.A., which is an insidious attack on medicine.

The council of the society has adopted a new and highly controversial policy, which its patrons and vice-presidents could hardly have anticipated when they lent their names. The society must, for example, be regarded as being in sympathy with the National Canine Defence League, which is also petitioning Parliament. The second paragraph of the league's petition runs as follows: "Your Petitioners are furthermore of opinion that, on account of this docility and obedience to the word of command, the dog has of late years been specially selected by vivisectors for extensive and peculiarly revolting and painful experimentation, and also for demonstrations of a prolonged and agonizing nature before classes of students." The substance of this statement is false, and no person having any acquaintance with the facts would have made it or would support it. The league ought to know, and we can hardly suppose it does not, that any experiment involving serious pain is forbidden by law, and no demonstration is permitted by law in which the animal is not under complete anaesthesia the whole time—an anaesthesia from which the animal is not allowed to recover. We hope that our readers will refer again to the report of the Science Committee on the use of dogs for experimental purposes, published in the JOURNAL of December 4th, 1926 (p. 1073).

SICKNESS BENEFIT CLAIMS.

IN Committee of Supply on Monday last the House of Commons considered Supplementary Estimates, which included those for additional grants necessitated by the very greatly increased claims made on approved societies for sickness benefit, both in England and in Scotland, during the last eight months of 1926. A report of the debate will be found on page 406. The Secretary and the Under Secretary for Scotland, and the Parliamentary Secretary to the Ministry of Health, all made statements pointing out the seriousness of the position, and emphasizing the facts that the increased claims were not general, but coincided very closely with the incidence of unemployment due to the coal dispute, and that as soon as this dispute ended these sickness claims immediately dropped by some 40 or

50 per cent. These speeches, on the whole, seem to have been fair presentations of the position; but they were all apparently taken by certain members to imply an accusation of improper or careless certification on the part of insurance practitioners. It is curious and a little refreshing to note that a defence of the medical profession against any such implication came from unusual and unexpected quarters on the Opposition benches; and the implication, at all events in this form, was disclaimed by Sir Kingsley Wood. It is perhaps less satisfactory to note that, so far as Scotland is concerned, Major Elliot felt that, as a member of the profession, he was at liberty to suggest laxness on the part of many of its members, while at the same time stating that he would "bitterly resent" such suggestions if made by laymen. Both these members of the Government, however, acknowledged that the Insurance Acts Committee and the Local Panel Committees had shown that they, equally with the Ministries, were alive to the importance of the matter, and were inquiring into the causes of the position which had arisen and as to any reforms or action which experience seemed to necessitate. It may be as well to note at once what steps have been taken in this direction.

It was at the October Conference of Local Medical and Panel Committees that Sir Walter Kinnear placed the facts, as then known to the Ministry of Health, before the representatives of insurance practitioners. At the earliest possible moment thereafter the Insurance Acts Committee, acting on the instructions of that Conference, wrote to all Local Medical and Panel Committees asking that all insurance practitioners in each area should be urged to bear in mind the strict conditions with which the claims for sickness benefit were surrounded, and not to allow any pressure on economic grounds to interfere with their full observance. This was effectively done in most of the areas concerned. The Insurance Acts Committee felt at the same time that there was room for inquiry into the exact causes which had brought about the great increase of the claims in areas most affected by the coal dispute, being sure that laxness in certification, however worthy the motive by which it might be prompted, was altogether insufficient to account for it. This inquiry was set on foot, and the conclusions to which it led have been placed before the Ministry of Health. It has become abundantly clear—as was, indeed, pointed out in the course of the debate in the House of Commons—that there are large numbers of insured persons who in normal times persist in working when they are really ill enough quite legitimately to claim sickness benefit. When the opportunity to continue at work is no longer present, such persons probably feel their ills more and seize quite properly the occasion to remedy them in the right way. Similarly, after an acute incapacitating illness the period of perfectly genuine convalescence extends to its full duration instead of being prematurely ended by an injudicious return to work. It is exactly in such cases that the greatest difficulty arises in determining just when a legitimate incapacity to work may be certified as ending. It is found, too, that there is an increasing tendency for the medical officers of maternity centres to advise insured women attending thereat to claim sickness benefit for longer periods both before and after confinement, and, as rest at these times is in itself good, it is very difficult for the insurance practitioner to refuse certification when this rest has been urged upon the patient by another responsible practitioner.

It is not denied that there have in some cases been causes at work less legitimate than these. The insured person has an ever-increasing appreciation of the opportunities which the insurance scheme offers to obtain financial help, and it is quite impossible for the doctor to be always confident in rejecting the statements of his patient. There have been instances, too, of collective pressure, as distinguished from doubtful individual claims, upon a practitioner to give certificates freely. Such pressure obviously increases the difficulty of the doctor's position, and means ought to be taken to protect him against it. Nevertheless, it appears probable that the traditional and natural desire of a doctor in presence of his patient to afford every help that he can possibly give may have outweighed the strict balancing of all the factors which go to determine "incapacity for work" in its narrower legal connotation under the Health Insurance Acts in a number of instances which, though proportionately small, may, in the aggregate, be large. It seems necessary to bring to the notice of insurance practitioners once more that it is these narrower, strictly legal, less sympathetic considerations which are imperative in connexion with the granting of medical certificates to insured persons, and that if the present insurance scheme is to continue to be successful they must constantly be borne in mind. In so far as the Insurance Acts Committee can emphasize this it is prepared to do so. But it is equally important that the inherent difficulties of the problem should be realized by others, and that everything possible should be done to avoid adding to these difficulties by meticulous rules and regulations and by improper pressure from any quarter.

THE CONSULTANTS' LONDON.

At the social evening of the Royal Society of Medicine on February 21st, when Sir James and Lady Berry received the guests, the Barnes Hall was crowded to hear Mr. Percy Flemming, F.R.C.S., speak on the topography and medical associations of the Harley Street neighbourhood. He extended the term to the whole area from Great Portland Street on the west, to Regent's Park on the north, and Oxford Street on the south, but did not strictly define the boundary on the east. Mr. Flemming had arranged an interesting collection of maps, plans, and old prints of what is now the borough of St. Marylebone, and illustrated what he had to say by a number of lantern views. Apart from the City, London had grown by taking in a number of villages, of which Marylebone was one. In Domesday it was in the manor of Ty-Bourne, and the windings of that now buried stream can be traced by Marylebone Lane, and its existence is indicated also in the distinct dip across Wigmore and Oxford Streets and further on. The lecturer brought out the interesting fact that it was the geological formation which determined in former days the limits of the residential quarters. The authorities of the City of London having impounded the Ty-Bourne, each new house in the Marylebone district had to be served by its own well, and this being the case it was obvious, Mr. Flemming said, that houses could not be built in any number on the clay, but only on the gravel brought down and spread out over the clay by the Thames. Beds of gravel existed under Marylebone. Here wells could be sunk at almost any point and water obtained. This need for water at a time when there was no public supply from distant reservoirs determined the line of London building, and accounted for the fact that certain areas which had no gravel or water-bearing beds were built over very much later. When the public water supply came Regent's Park

itself had a narrow escape, for plans were got out to cover it with houses. From contemporary chronicles and maps Mr. Flemming conveyed an idea of the rural character of the more northerly part of the Harley Street district, even down almost to the end of the eighteenth century. Building developments to the north of Cavendish Square began about 1717, but even eighty years later Harley Street had not reached as far as the Marylebone Road, and the part of Harley Street which was Crown property had not been developed. Harley Street was not at first a street of medical residents. It was a favoured place of residence for the "nobility and gentry." Boswell, who lived in the neighbouring Queen Anne Street in 1788, described it as "genteel," by which he meant aristocratic, and much later Mrs. Gaskell, in her *North and South* (1855), made Harley Street the residence of a nobleman's family. The street at that time had its quota of general practitioners, and quite a number of names of general practitioners in Harley Street were to be found in the issue of the *Medical Directory* for 1847. The headquarters of the consulting part of the profession were at first in the City, where there was a large resident population, as well as easy access to four big hospitals, while another group, including Hunter and Brodie, of St. George's, lived in the Piccadilly neighbourhood. Of the fifty-two original members of the Medical and Chirurgical Society, which was founded in 1805, only nineteen lived in the West End. Later, when the population began to move westwards, the profession followed, making a halt in Bloomsbury, where Abernethy lived. When the profession finally got to the West End its locality was, not Harley Street, but certain streets south of Oxford Street, around Hanover Square, and between Piccadilly and Bond Street. Robert Liston in 1833 lived in Clifford Street, off Bond Street. Syme, the great Edinburgh surgeon, when he was for a few months on the staff of University College Hospital, went to live in Bruton Street, also off Bond Street. Later Cavendish Square, on the north of Oxford Street, attracted a few medical residents. Richard Quain, the surgeon, moved there in 1850. Sir George Burrows, who was president of the Medical and Chirurgical Society in 1869, also had a house in Cavendish Square. Gradually the square became the fashionable quarter, and every young consultant, if he could not get a house in the square itself, tried to get one as near as possible, and thus Harley Street, leading from its north-western corner, filled up. Sir William Jenner took a house in Harley Street in 1851, though in 1868 he moved into Brook Street. By 1870 the tide had definitely set in the Harley Street direction, and Wimpole Street, to a smaller degree, at first shared its popularity. It might be said, therefore, that for the first hundred years of its existence Harley Street was the home of the aristocracy, and for the following fifty years the home of the medical consultants. What, asked Mr. Flemming, would be its future? Would it continue indefinitely to be a street of consulting rooms? There were evidences already of an invasion of the street by commercial firms, and the profession was now beginning to trickle northwards across the Marylebone Road. Would the "herd" regard these adventurers across the border as leaders, and follow them, so that the home of the consultants would presently be, not Harley Street, but the Outer Circle of Regent's Park? Time would show. In proposing a vote of thanks to the lecturer, Sir D'Arcy Power mentioned that he remembered his father in 1870 debating the question whether he should move into Harley Street, but as at that time the rent of a Harley Street house was £100 a year (!) and the rates £50 more, he decided, having eleven children, that this was too expensive. Dr. Walter Carr, in seconding, indulged in a prophecy with regard to the Harley Street of fifty years hence. He saw the smaller houses demolished, and the great houses enlarged to become the homes of medical "teams." Sir James Berry drew attention to one curious fact which came out in Mr. Flemming's maps—namely, that what is now called Chandos Street formerly bore the name of Harley Street.

HOSPITAL DIFFICULTIES IN CHINA.

TEN months ago Dr. James Maxwell, secretary of the China Medical Association and editor of its journal, reported the forcible closing of Canton Hospital by a labour organization (JOURNAL, 1926, vol. i, p. 753). He now describes in the February issue of the *China Medical Journal* the anxious position of the J. G. Kerr Hospital for the Insane in Canton, which is threatened with interference of a similar kind. This hospital, which is described as being the only well equipped and efficiently run institution of any size in China for the insane, accommodates between 700 and 800 patients under normal conditions. Its governing body has now received a series of provocative demands from the local labour union, to which some of the hospital attendants belong. These requirements include an admission that the hospital employees are free to talk, to publish any matter desired, and to strike; while they may not be reprimanded or discharged, or their work changed, without the consent of the union, whose nominees alone may be employed by the hospital. The minimum wage of an employee is to be 15 dollars a month, with board, and double wages for the last months of the year; four suits of clothes are to be provided also. Wages must increase each year, and, in addition to this, it is stipulated that all special demands for other increases must be granted. Double wages are to be paid to employees remaining at work on public holidays and national parade days. The hospital must contribute money towards the establishment of schools for the benefit of the employees, but are not to require any to study who feel disinclined to do so. As no institution could be administered under such deliberately impossible conditions, the directors of the J. G. Kerr Hospital approached the responsible department of the Cantonese Government, and from it a certain amount of sympathy was received. Attempts made to arrange a meeting between the Government, the hospital, and the labour union were abortive, however, owing to the failure of the Government representatives to appear. The hospital authorities, after consultation with the local branch of the China Medical Association, drew up a statement of the basic principles of employment in hospitals, and asked to be protected from strikes, forcible closing, intimidation, or any outside illegal interference. The outcome of the matter remains in doubt, and Dr. Maxwell adds that, while it appears that the Southern Government of China views medical work in its area with a benevolent eye, it is very doubtful how far the communistic and Bolshevik elements in the labour unions can be controlled.

THE NATIONAL UNION OF SCIENTIFIC WORKERS.

AN appeal for increased support has been issued by the National Union of Scientific Workers, which was founded in 1918 to promote the cause of science in the national life, and to improve the status of those engaged in scientific work. The present membership of the union is a little under 1,000, although there are thought to be nearly 10,000 persons in Great Britain eligible for admission. Among the large number of signatories to the appeal are statesmen of differing political views, many leading industrialists, and representatives of medical science, including Sir Humphry Rolleston, Sir Charles Sherrington, Sir David Bruce, Sir F. Gowland Hopkins, Professor R. T. Leiper, Professor Swale Vincent, Dr. Major Greenwood, and Dr. Charles Singer. It is believed that the establishment of

such a representative body as is contemplated would be of the greatest importance to science and to those who are devoting their lives to it. The union aims at promoting the general interests of the scientific profession as a whole; it claims to be entirely non-political, and to have been already markedly successful in improving the conditions of groups of scientific workers in Government and private employ. It has been represented upon, or given evidence before, various Government committees when the interests of scientific workers have been involved, and it has intervened successfully to prevent curtailment of the activities of research institutions supported by public funds. With better support the union might hope to obtain more effective representation of scientific workers on bodies set up to consider problems of national, imperial, and international importance. It would be able to view the whole field of research comprehensively and suggest useful lines of advance. A code of professional ethics could be drawn up, and a complete register made of those engaged in scientific work. The union has never contemplated the possibility of a strike, since this is looked upon as a weapon that scientific workers could not use. The present annual subscription to the union is 30s., but with any considerable addition to the membership this could be reduced substantially.

ST. DUNSTAN'S.

"LIGHTEN our darkness." These familiar words form the title of the eleventh annual report of St. Dunstan's, for the year ending March, 1926. The words epitomize the aim of the founder of this beneficent organization for the care of blinded sailors and soldiers of the great war. The aim has been realized in the great majority of cases, for through the efforts of St. Dunstan's most of the men who have gone there for training have been taught some useful employment and been enabled to become to a greater or less extent economically independent. Such a realization is surely light in darkness. Occupation is the salt of life to everyone, and to none more so than to the physically disabled, and particularly the blinded. The organization has not only trained the men, but it acts as a continuous agent for them. It provides the workers with the raw material necessary for their industry, buying for them on terms which they could not separately secure. It further collects the products of their work and markets it for them, again at an advantage as compared with what they could secure locally and in retail fashion, for not every producer is a good salesman. During the past year the value of the goods produced has increased by nearly £10,000—a sign that the workers are both more efficient and more productive. But this notable increase is not without its difficulties to the administration. In a year of falling markets and industrial stagnation sales were more difficult to effect, so that at the end of the year the council found itself with an accumulation of saleable goods for which there was no ready market. If the organization were a strictly industrial concern this would inevitably mean a lessening of production, a course which cannot be adopted, for it would be likely to have a bad effect upon the morale of the men. The difficulty is not solved, and therefore a special plea is made that buyers will consider the goods of St. Dunstan's wherever that is possible. Enclosed in the report is an attractive trade catalogue of the goods on sale. The range covers baskets of all sorts, both of workaday and fancy types, trays, occasional tables, mats and rugs, netted goods of many kinds, string bags, and some woollen goods. All goods are "marked in plain figures." Last year the council instituted a new departure. The Widows', Orphans', and Old Age Pensions Act of 1925 applies in the main to employed persons; those who "work on their own" may join in this insurance provided they pay both their own contribution and what would for employed persons be the employer's contribution. The advantages of this form of thrift for blind men was studied, and the conclusion was formed that it would furnish a most satisfactory provision. But there was this difficulty, that the means of the blind did not suffice for the double contribution. The council accordingly decided to pay the employer's half, assuming a liability that was purely an act of grace, but which seemed to fall within the scope of the scheme. The men have taken full advantage of this offer, so that 986 have already taken it up—that is, 80 per cent. of those eligible for this form of insurance. The report gives full information of the working of St. Dunstan's, with detailed balance sheets. The address of the offices is St. Dunstan's Headquarters, Inner Circle, Regent's Park, N.W.1.

THE ART OF MEDICAL PRACTICE.

"WHATEVER houses I enter, I will go into them for the benefit of the sick." This familiar phrase from the Hippocratic Oath sums up the first and fundamental rule of medical ethics, and all who read with due attention Mr. E. B. Turner's address to new graduates and senior students, printed in the SUPPLEMENT this week, will recognize that it is the underlying theme of his discourse. Whether at the bedside or in the surgery, in his relations with colleagues or in his attitude towards cults and charlatans, the doctor's first care must be the good of the patient. The lecture touches on varied aspects of medical practice; its many hints and cautions to young practitioners are drawn from a ripe experience of fifty years' professional work; and the advice on matters large and small is a wholesome blend of idealism and shrewd common sense—two essential ingredients in the make-up of a good family physician. Success in private practice, as has often been remarked, demands a great deal of knowledge beyond that gained in the medical schools, and it is just this kind of knowledge that Mr. Turner imparts. With such guidance some of the pitfalls of the earlier years of professional life may be avoided, for though it is true that we learn by our own mistakes, experience so acquired can often be bought too dearly. Particularly interesting and helpful to those who are still *in statu pupillari* is the contrast Mr. Turner draws between hospital cases and the cases commonly seen in private practice; and the emphasis he lays both on the need for keeping up anatomy and physiology and on the incalculable value of house appointments. One among many sound pieces of practical advice might well be inscribed on the title-page of every visiting list: "However much you may be tempted, never palliate symptoms only—get right down, try to discover the cause of the trouble, and, if possible, remove it." And the final-year students of to-day could do worse than copy into their notebooks these sayings: "Above all things never become slaves to your instruments. . . . Every general practitioner should be prepared to accept and face his own responsibilities. . . . A good physician never treats the illness, but always the patient." Truisms, perhaps; but, as their context shows, they go straight down to bedrock in the art of medical practice.

INTERNATIONAL CONGRESS OF MILITARY MEDICINE AND PHARMACY.

AFTER the war the idea occurred to the Belgian army medical authorities that advantage should be taken of the medical experiences of the war in order to arrive at definite conclusions with regard to a number of questions affecting military medical practice and organization. In

pursuance of this idea an International Congress of *Military Medicine and Pharmacy* was held in Brussels in 1921, when an International Association of Military Medicine and Pharmacy was inaugurated, with a small permanent committee and with the *Archives Médicales Belges* as its official journal. A short account of the congress appeared in June, 1922, in the *Journal of the Royal Army Medical Corps*. A second congress was held in Rome in 1923, and an entertaining account of it, by Colonel D. Harvey, was published in the same journal in August, 1924. Arrangements had been made to hold these international congresses every two years, and consequently the third congress took place in 1925, this time in Paris, but hitherto no report of it has appeared in the British military medical journal. We are therefore all the more indebted to Commander Bainbridge of the Medical Corps of the United States Naval Reserve Forces for a series of articles in the *Military Surgeon* of May to August, 1926, which the Association of Military Surgeons of the United States has now reprinted in a separate volume.[1] It contains an interesting and detailed summary of the various papers read at the meetings of the congress, the chief subjects discussed being technical specialization, selection of recruits with reference to tuberculosis, the etiology and treatment of traumatic arthritis, and the analysis of dressing and suture material. Although several British officers, including the late Sir William Leishman, attended the congress, none appear to have read papers or taken part in the discussions. The next congress is to be held in May next at Warsaw, and it is understood that it will be followed by a fifth international congress in London in 1929.

R.S.P.C.A.

WE regret to announce that the Royal Society for the Prevention of Cruelty to Animals, by a majority vote of the council, has now changed its policy and become in practice an antivivisection organization. The society is promoting a petition to Parliament praying it to pass the Dogs Protection Bill (of which the text appears in our Parliamentary column), and thus bring to an end all experiments on dogs. It was hoped by its well-wishers that the society, after the recent fiasco regarding the export of old horses for butchery on the Continent, would have taken some pains to prevent misleading statements appearing in its future propaganda, but a pamphlet which it is circulating to stimulate the signing of its petition contains the following paragraph: "From replies to questions asked in the House of Commons, we learn that 'during 1925 and 1926, 1,147 dogs have been used for experimental purposes at University College alone, of which 21 were used for demonstrations before students and 28 were not kept under anaesthetics during the whole of the experiments.'" In such cases the experimental animals are given anaesthetics carefully and individually so as not even to frighten them. At a dogs' home a number of animals may be put into lethal chambers *en masse*. A point we particularly wish to make is that in 1,119 cases out of 1,147—that is, 97 per cent.—the dogs used were destroyed as humanely, if not more humanely, than at a dogs' home, and entirely without pain or discomfort. Special Home Office regulations safeguard the other 3 per cent. from serious pain. The council of the society has taken a grave step in thus associating itself with the various antivivisection societies. It has vacated an impregnable position which appealed to all right-minded people, and particularly to medical men, for one of fanaticism which we know is, in reality, opposed to the welfare, not only of the general public and the medical profession, but of dogs themselves. George Eliot said: "I call a man fanatical when his enthusiasm is narrow and hoodwinked so that he has no sense of proportion, and becomes unjust and unsympathetic to men who are out of his own track." The educated public in this country are whole-heartedly with the medical profession in its endeavour to alleviate suffering and disease in animals as well as in man, and we believe it is the duty of the profession to instruct the public as to the nature of the retrograde step now being taken by the R.S.P.C.A. The change in policy is such that the society cannot retain the public confidence so long as it continues in this new course.

[1] *Report on Third International Congress of Military Medicine and Pharmacy, Paris, April, 1925.* By Commander William Seaman Bainbridge, M.C. Washington: Reprinted from *The Military Surgeon*, May to August, 1926, inclusive. (5½ × 9, pp. viii + 111; illustrated.)

PUBLIC ASSISTANCE FOR RIVER POLLUTION RESEARCH.

A JOINT committee of the British Waterworks Association and the Salmon and Trout Association recently addressed to the Prime Minister a memorandum on the pollution of rivers. On February 15th Lord Balfour received a deputation from these two and other bodies on the subject of the memorandum. The topic is no new one, and the appendix to the memorandum is a review of the findings of Royal Commissions and of committees which have had the matter under consideration from various aspects from 1866 to the present time. Each report has emphasized the seriousness of river pollution; in practically every report some form of central control of watersheds and rivers has been recommended. The results of these reports have been so meagre that the British Waterworks Association and the Salmon and Trout Association feel entitled to speak of the "progressive" pollution of the rivers of England and Wales as a menace to the well-being of the community. With the growth of population in large towns practically all the areas in which water can be impounded have been taken up, and underground supplies have greatly diminished. In fact, the medical officer of health for Essex, in a recent report, stated that for his county the limit of supply from underground sources had already been reached; and, all suitable rivers having been appropriated, the only source for the necessary extension of the supply of water was the river Stour, a polluted river belonging partly to Essex and partly to Suffolk. The main sources of pollution are sewage, increased by the conversion in many districts of privies and pail closets to the water-carriage system, and trade effluents. With the latter the difficulty in many cases is to discover a method of dealing with them without interfering with the prosperity of industry. This difficulty has been illustrated lately by the disastrous effects on fish life of effluents from beet sugar factories. It is pointed out in the memorandum that for pollution by many trade effluents science has so far been unable to find a remedy. The joint committee calls attention to the excellent results that have been obtained in some rivers, where public spirit has aided the efforts of local authorities and river boards, and pays a tribute to the administration of the Thames Conservancy Board. The deputation urged on Lord Balfour the appointment of a central committee of about five representatives of departments and boards, with power to co-ordinate varying interests for the purpose of reducing the pollution of all rivers and estuaries in England and Wales. It was suggested that this authority should be directly under the Privy Council, and that research should form an important part of its functions. Lord Balfour, in reply to the deputation, said that the Government was prepared to supply the necessary financial resources to see that scientific investigations were adequately carried out. Scientific research, he said, would require *not only* laboratory experiments, but full-sized

manufacturing experiments; and for this the co-operation of the interests most nearly affected might be required. In addition the scheme of river boards should be extended. But Lord Balfour held out no hope of the Government establishing at present a central authority; those, he said, who used the "magic phrase" did not seem agreed as to the precise powers to be given to the authority, and what relation it was to bear to present Government organizations. A perusal of the memorandum suggests that the views of the joint committee were somewhat nebulous on these matters. A further reflection may occur to some people that, inasmuch as even manufacturers probably drink water in one form or another, it is curious that they do not display greater personal and private interest in the source of their supply.

INFLUENZA.

THE decline of mortality from influenza noted in our last issue has unfortunately not continued, and last week the number of deaths registered in the great towns of England and Wales increased from 759 to 990. This increase is due to the spread of the epidemic in the north and north-west, a process which has more than counterbalanced the decline in the south (in London the deaths last week decreased again, from 159 to 128). The age distribution of the deaths continues to be of the normal type—that is, showing a large proportion of older persons—contrasting greatly with the state of affairs noted in the great pandemic of 1918-19. The special reports furnished to the Scottish Board of Health by the medical officers of health of the sixteen principal towns and the county medical officers of Lanark and Fife show that there has not been much change in the prevalence of influenza in Scotland during the week ended February 19th. In Glasgow and Edinburgh there are not an abnormal number of cases, while Aberdeen reports a decrease in incidence. Influenza accounts for more absences from Dundee schools than in the previous week, but there is no other indication in the city of a heavier incidence. More cases are reported from Greenock, Motherwell and Wishaw, Coatbridge, Dunfermline, Kirkcaldy and Hamilton, and the county of Lanark, except the Lower Ward and Lanark Burgh. In Kilmarnock the disease is prevalent in a mild form, and there are a good many cases in Inverness and surrounding districts. On the other hand, incidence is definitely lower in the county of Fife, except for a few limited areas. In Scotland, as elsewhere, the epidemic has been generally of the mild catarrhal type.

RESEARCH DEFENCE SOCIETY.

THE January issue of the *Fight Against Disease*, the journal of the Research Defence Society, deals at some length with the two cases relating to the use of dogs for experiment heard in the courts at the end of last year. A reasoned statement by the honorary secretary of the society, Dr. G. P. Crowden, on the principles involved in the use of animals for research provides a timely reminder of the safeguards which are invariably in operation, and indicates some of the benefits which have been obtained. A similar note is struck by an article entitled "Research or suffering?" in which the success of the experimental method of investigating disease is further vindicated. The suggestion is repeated that 1,000 of the 50,000 dogs annually destroyed in the lethal chambers of the dogs' homes in London should replace the animals which have at present to be obtained through private agencies. The memorandum of the Science Committee of the British Medical Association on the use of dogs in physiological and therapeutic experiments is reprinted from the BRITISH MEDICAL JOURNAL of December 4th last. This number of its journal is, therefore, a sound and weighty appeal for more support of the Research Defence Society, of which the president is Lord Lamington and the chairman Lord Knutsford. Arrangements are made by the society for addresses and lantern lectures, and for the supply of literature to clubs and institutes. The subscription for members is 10s., and for associates 5s. Further information may be obtained from the honorary secretary, Dr. G. P. Crowden, at the address of the society, 11, Chandos Street, W.1.

BRITISH CONGRESS OF OBSTETRICS AND GYNAECOLOGY, 1927.

THE sixth British Congress of Obstetrics and Gynaecology will be held in Manchester on Wednesday, Thursday, and Friday, April 27th, 28th, and 29th. The main subject chosen for discussion is the treatment of inflammatory conditions of the uterine adnexa. This will occupy the first day. The remaining days will be devoted to short papers on obstetrical and gynaecological subjects, and to demonstrations of surgical operations. In connexion with the Congress a museum of pathological specimens is being arranged. The secretaries of the Congress are Professor Daniel Dougal, 11, St. John Street, and Dr. John Bride, 2, St. John Street, Manchester, to one or other of whom all communications should be addressed. Those wishing to take part in the principal discussion, or to contribute short papers, should send in their names immediately, giving the title of any proposed contribution. The last congress was held in London in April, 1925.

THE Home Secretary has informed the British Medical Association that he has appointed Dr. J. W. Bone (a member of the Council of the Association) and Dr. T. K. Monro (Regius Professor of Practical Medicine in the University of Glasgow) to be members of the tribunals under the Dangerous Drugs Regulations (1926) for England and Scotland respectively, and has appointed the other medical practitioners named by the Association to be substitute members of the respective tribunals. Sir Humphry Rolleston has been appointed chairman of the tribunal for England, and Sir Robert Philip chairman of the tribunal for Scotland; the respective legal assessors are Mr. E. W. Hansell, M.A., and Mr. John Cowan, K.C.

AMONG the fifteen candidates recommended for election into the Royal Society of London at a meeting of the Council on February 17th were: Dr. T. G. Brown, professor of physiology and dean of the Welsh National School of Medicine; Mr. Richard Higgins Burne, M.A., physiological curator of the Royal College of Surgeons of England since 1912; Dr. P. P. Laidlaw, a member of the Department of Experimental Pathology of the Medical Research Council; Dr. J S. B. Stopford, professor of anatomy at Manchester; and Dr. C. M. Wenyon, director of the Wellcome Bureau of Scientific Research.

THE Council of the University of Leeds has gratefully accepted an offer by Mr. L. R. Braithwaite, surgeon to the Leeds Infirmary, to present to the Medical School a bronze bust of Sir Berkeley Moynihan.

THE Sir William Dunn School of Pathology at Oxford will be opened on the afternoon of Friday, March 11th, by Viscount Cave, Lord Chancellor of England and Chancellor of the University.

Nova et Vetera.

CZECHO-SLOVAK MEDICINE.

THE UNIVERSITIES AND THEIR MEDICAL CLINICS.

IN the rearrangement of Europe which resulted from the war many things have been gained, but some, we think, have been lost, and one of these latter is the romantic name of Bohemia, which has disappeared in the title of the much larger republic of Czecho-Slovakia. To all Western peoples the name of Bohemia has been associated with romance, whether in connexion with "La Vie de Bohème" or with the gipsy folk who have been inaccurately supposed to come from that kingdom. To Englishmen in particular it has been bound up with recollections of that British princess who became for a time its "Winter" Queen—her descendant occupies the throne of this country to-day. She inspired much romantic devotion among our countrymen in general, and especially in that public-spirited Lord Craven, whose bequest of land to maintain a pest house is represented by Craven Hill, Bayswater, and is still a source of revenue devoted to public purposes. In Bohemia, too, Shakespeare placed one of the most charming of his pastoral scenes and endowed the country with a sea-coast which even the enlarged Czecho-Slovakia still lacks. The ancient kingdom suffered many vicissitudes and was the scene of many evil deeds perpetrated in the name of religion, until at last it fell a prey to its unscrupulous and too powerful neighbours and seemed to have sunk into perpetual vassalage to the house of Habsburg. But in spite of all attempts to make them German, the Czech people always preserved their national spirit and their language until, as John Hay wrote of another country,

> "God maddened the Greedy Kings
> And gave to its people"—Prague!

Since the end of the war the Czecho-Slovakians have shown themselves to be the most progressive and energetic of the new nationalities, not only in material things, but also in those of the mind. In an address recently delivered in English before the Inter-State Post-Graduate Association of North America, Professor Ladislas Syllaba, M.D., who is president of the Czech Medical Society of Prague, gave a most interesting review of the development of Czech medical science.

The University of Prague was founded so long ago as 1348 by Charles IV, King of Bohemia, and can thus claim to be the first university of Middle Europe. In the words of the original charter, this was done "in order that the loyal inhabitants of the kingdom who are ever hungry for the fruits of science should not be driven to beg of strangers, but should find their table spread with food in their own kingdom." So many foreign students resorted to this University that they threatened to squeeze out the native scholars, and early in the fifteenth century it was found necessary to give the Czechs a preponderating voice in its management. It is said that as a result as many as twenty thousand Germans left, and that the University of Leipzig was founded for their benefit on the pattern of that of Prague. This last-named University flourished until the catastrophe of the battle of the White Mountain, in the course of the Thirty Years War, and the successes of the counter-reformation resulted in its being shorn of some of its faculties, which were transferred to a Jesuit academy. The present Czech University at Prague is called from its original founder the "Charles University," but during the Habsburg despotism its name had been changed to "Carolo-Ferdinandean," after the Emperor Ferdinand III; by this act, Professor Syllaba says, "the name of the great founder was joined in bitter irony with the name of the representative of a dynasty that for the University, for the nation, and for the whole of Europe, was a calamity." But even after 1867, when the non-German portions of the Austrian patchwork empire received some measure of liberty, the Germans and Czechs did not work harmoniously together, and in order, no doubt, to strengthen the German position a separate German university was founded in Prague in 1882, and the old University had its full faculties restored to it. The German institution still flourishes, for there is a large and energetic German population in Bohemia.

Since the establishment of the republic two more Czech universities have been founded, one in Brno—long known as Brünn—in Moravia, and one in Bratislav in Slovakia, on the Danube in the fortress-city formerly known as Presburg. Thus it will be seen that there are four universities in Czecho-Slovakia, so that the higher education of its fourteen million inhabitants is well provided for.

The Czech Medical Society of Prague, which has been at work since 1862, played a great part in promoting medical and surgical knowledge and the study of the ancillary sciences. The name of John Everard Purkyné, which the Germans have phoneticized into their own language as Purkinjé, is known all over the world as that of a physiologist, histologist, and comparative anatomist. He had done much good work in the Silesian University of Breslau before he came back to Prague in 1850. He not only founded the society, but also at the same time its necessary accompaniment, the "Journal of Czech Medicine." The achievements in science of the men the society and its journal helped to bring forward were of such a high character that it became impossible for the Viennese Government any longer to postpone the establishment of a Czech university, with all the usual faculties. Accordingly the Czech professors exchanged their chairs in the Carolo-Ferdinandean University for analogous ones in the new institution, while their posts were filled by Germans in the now Teutonized old university. Their task was hard, for not only had new buildings to be provided and libraries and museums furnished, but scientific instruments and even handbooks for students had to be written and printed in the Czech language. But no difficulties could daunt the patriotic and scientific fervour of the Czechs, and their success was evident in the transactions of the Academy of Sciences and Arts and at the conferences of Czech physicians and naturalists held in 1901, 1908, and 1914. Revival after the war was much helped by the financial support given by the Rockefeller Foundation in reorganizing various institutions and completing equipment and bringing libraries up to date. New medical societies have sprung up in connexion with the new universities, and it is evident that scientific progress in the republic is as vigorous as its industrial development.

We are indebted to Professor Prusik of the (Czech) University of Prague for giving us the opportunity of reading Professor Syllaba's address, and also for some other documents from which we learn that there are two medical clinics in the University, the one under the direction of Professor Syllaba, and the other under that of Professor Pelnar; Professor Prusik, who belongs to the latter, has given a sketch of the scientific research carried on by it. At the present time the work is handicapped by the fact that building operations are going on, but the staff is large and is kept fully employed. It consists of three clinical assistants, of three hospital secundarii, of extern assistants (who never number fewer than twenty), and of auxiliaries recruited from among the medical students. Professor Pelnar, who is known for his writings on disorders of the nervous system, gives five clinical lectures a week, and Professor Prusik himself, who is in charge of the cardiological laboratory, supervises a group of workers in the diseases of the heart and blood vessels; this group is in charge of out-patients suffering from diseases of this nature. The clinic has a section for physical therapy, another for metabolic disorders, and another for tuberculosis. New chemical laboratories are being erected, and there is a good æ-ray equipment.

Nationalism has its drawbacks, one of the chief of which is the danger of increasing the barriers formed by differences of language. No doubt it was more convenient for the outside world when the works of Czech men of science were published in French and German and so made accessible, but the price to be paid for this convenience was too high, and the increased production of important researches and discoveries stimulated by the national spirit, which not all the years of German-Austrian domination could crush, compensates for the language difficulty, which will also be evaded by translation of the more important publications.

Union of South Africa.

[FROM OUR CORRESPONDENT IN JOHANNESBURG.]

ANTIPLAGUE MEASURES.

PLAGUE has now for several years been enzoötic among the veld rodents in certain parts of the country, and has been spreading extensively. The gerbille, or nagmuis, is the rodent chiefly responsible for this spread, because of its migratory habits. Fortunately the soil is not everywhere suitable for this animal, and it avoids human habitations. A rodent survey of the Union revealed that about one-third of the country is relatively free from the gerbille. This area includes the southern coastal parts of the Cape Province, the smaller blocks of country further north in the Cape, Natal, Orange Free State, and the Transvaal. All the rest of the country has soil suitable for gerbilles, and in grain lands in these parts their burrows are usually plentiful. In this gerbille area plague has been steadily spreading, until now only about one-third of it can be considered to be free. The gerbilles are, however, entirely wild veld rodents, and their burrows are seldom found in the vicinity of human habitations. This is held to account for the fact that human cases of plague are relatively infrequent, though each summer a few are reported, usually from points very far apart. The connecting link between the gerbille and man appears in many cases to have been the multimammate mouse—a wild rodent found round about farmhouses. This animal, as also the wild striped mouse, is frequently found dying of plague. Both kinds occur in disconnected patches, are not migratory in their habits, and are therefore unlikely to be responsible for extensive spread of the disease. It is, then, against the gerbille that preventive measures have to be taken.

Until last June the Cape Peninsula was not considered to be in any danger from plague, even though the whole of the west coast, from the peninsula northwards, is soil ideally suited to the gerbille. The nearest known plague infection was some four hundred miles away to the north-west, beyond Kenhardt. Then quite unexpectedly human cases were reported at Calvinia, only 200 miles from Capetown. Investigation showed that the disease had spread extensively amongst the rodents of the sparsely populated intervening area. It became necessary for the Health Department to consider the safety of Capetown. From the massive block of mountains between Stellenbosch and Worcester, a narrow range separates itself and runs due north for 200 miles to beyond Van Rhynsdorp. This range itself is gerbille-free, but on both sides of it is gerbille country. At its northern end the Calvinia district lies on its east side, and here the gerbilles are plague-infected. Plague can advance on Capetown round the northern end of this range and down its western side. The width of the strip of land lying between this range and the Atlantic is, on an average, sixty miles. On it are extensive grain lands, and the gerbille everywhere flourishes. Were no precautions taken, plague might be expected to advance rapidly down this strip towards Capetown. To prevent this the Health Department has put a barrier across the strip between the mountain range and the sea, in the shape of a gerbille-free belt. The Olifants River flows across this strip of country in a north-westerly direction from Clanwilliam to the sea. This river will effectively prevent the crossing of gerbilles during the greater part of the year, when it contains water. From the sea for a distance of about fifteen miles to a place called Koekenaap, it is wide and deep throughout the year, receiving tidal flows. Twelve miles south of Clanwilliam a weir crosses the river, and a wide stretch of water is piled behind it for many miles. Between the weir and Koekenaap the river is liable to become a series of disconnected water-holes during the drier summer months. It is this stretch of some sixty miles which is in danger of being crossed by plague-infected gerbilles from the north; and it is the northern bank of this portion of the river which the department is attempting to keep rodent-free.

Four gangs of natives and Eurafricans are working under departmental rodent officers, and the first clearance of this belt of rodents has just been completed. The methods adopted against gerbilles and striped mice consist of poisoning; against Karroo rats, of gassing the burrows and burning the nests. These methods are very effective, and it is estimated that over 90 per cent. of the rodents are destroyed. Poisoning is by strychnine-impregnated grain. The employees provided with this grain spread out in a line fairly close to one another, and drop a few grains into each burrow as they advance. The gerbille (nagmuis, or night-mouse, as it is called in Afrikaans) comes out of its burrow after sunset. Next morning early numerous carcasses may be seen lying about on the surface, but they do not remain there long, as eagles, owls, and night-prowling carnivorous animals follow the activities of the rodent gangs with interest, and speedily devour the bodies of the dead. The birds seem to suffer no harm from this diet; they do not consume the intestines containing the poisoned grain.

Gassing is performed near homesteads, where the laying down of poisoned grain might be dangerous to domestic animals. A cartridge is lighted, plunged into a burrow, and the opening of the burrow closed with earth. The natives stand by with spadefuls of earth, and wherever smoke emerges—indicating a connexion with the gassed burrow—the opening is closed. This method produces a 100 per cent. kill, but is much more laborious than the poisoned grain method. The average width of the belt so cleared is about a mile; the gangs advance about half a mile a day. Having now completed a first clearance, the gangs will work over the same belt for a second time. This belt will afford very considerable protection against plague carried by the small rodents, but one grave danger persists. South of Clanwilliam, at a place called Citrusdal, hares are very abundant; these animals have been known to travel tremendous distances in a night. It is thought that they were largely responsible for the rapid spread of plague from Kenhardt to Calvinia last year. Should plague travel down the east of the mountain range to a point opposite Citrusdal, infected hares might readily carry the infection across the range. The Health Department is alive to this danger, and round about Citrusdal the country is being extensively cleared of rodents by a special gang. Even such a wide area is liable to be crossed by migratory hares.

MEDICAL ASSOCIATION OF SOUTH AFRICA (B.M.A.).

On January 8th, 1927, there appeared the first number of the official journal of the Medical Association of South Africa (B.M.A.). Previously there had been two privately owned journals—the *Medical Journal of South Africa*, published in Johannesburg, and the *South African Medical Record*, published in Capetown. After success had crowned the continuous efforts to combine the two medical associations (efforts which had lasted many years, and which had at times seemed merely to be increasing and rendering more bitter the points of difference between the two bodies), the need for an official organ of the new association was felt. The directorates of the two existing journals were approached, and they generously agreed that the individual journals should be merged into a single official journal. The atmosphere in the profession is one of peace and co-operation. The first number of the new journal exhales this atmosphere happily. Its staff has the confidence of the profession. All members of the Association will feel a personal and proprietary interest in the *Journal of the Medical Association of South Africa* such as they could hardly have had in its predecessors, however loyally these papers tried, as undoubtedly they did, to promote the interests of the profession. The desire for unity in the profession had been growing, but it would be difficult to exaggerate the good services of Dr. Cox a year ago. To his genius for organization the profession in South Africa will ever be indebted. The Federal Council of the united Association is a representative and powerful body. Its president, Dr. A. J. Orenstein, is a man of enthusiasm and remorseless energy, possessed of an instinct for organization that is quickly recognized by anyone with whom he comes into contact. As an organizer he

is in the first rank, as his career testifies. He was on the medical staff under Gorgas during the construction of the Panama Canal. He served as sanitation officer before the war in German East Africa (1913-14). During the war he was Director of Medical Services for the South African Forces. He is superintendent of sanitation of the Rand Mines, Limited, and the splendid organization of the medical services of that group bears eloquent witness to his ability. Last year, in spite of his already numerous and onerous duties, he accepted the presidency of the South African Red Cross Society (Transvaal); he has for long been the moving spirit in that virile body, and his election to the presidency was richly deserved. At this early stage of the existence of the Medical Association of South Africa, when enthusiasm and organizing ability are so greatly needed, the Federal Council has clearly appointed the obvious man to lead it.

Scotland.

THE ROYAL SOCIETY OF EDINBURGH.

THE Council of the Royal Society of Edinburgh has recommended thirty-one persons for election as Fellows at the March meeting; among them are the following medical practitioners: Dr. J. M. Munro Kerr, Muirhead professor of midwifery and gynaecology in the University of Glasgow; Dr. C. G. Lambie, lecturer in clinical medicine and assistant in therapeutics, University of Edinburgh; Dr. D. McIntyre, assistant to the Muirhead professor of midwifery; Dr. F. N. K. Menzies, medical officer of health and school medical officer for the County of London; and Mr. T. P. Noble, M.B.Ed., F.R.C.S.Eng., professor of surgery, Bangkok University, Siam.

PUBLIC DEBATE ON VIVISECTION.

A public debate dealing with experiments on animals was held on February 11th in the Synod Hall, Edinburgh. Mr. Robert Lawson presided, and the leading speakers were Dr. J. H. Burn, M.A., M.D., director of the pharmacological laboratory of the Pharmaceutical Society of Great Britain, in favour of the value of animal experimentation, and Mr. Herbert Brown, who argued against vivisection. Dr. Burn said he spoke as a person who habitually, in the course of his work, carried out experiments on animals. Medical treatment at the present time, and in particular surgical treatment, was dependent on experiments performed on animals. Operations done to-day rested on the discoveries of Lord Lister, who had himself said that more was to be attributed to experiments on animals than to any other work on which he was engaged. Mainly through experiments on animals medicine had advanced a long way towards the cure of syphilis. Insulin, which had transformed the whole aspect of diabetes, was purely the result of experiments on dogs. Experiments on dogs had indicated the means by which no child need ever run the risk of having rickets. The whole outlook towards cancer had been transformed by animal experiment, and there was now the greatest probability that cancer would ultimately be found to be preventable. Very grave responsibility rested on anyone who said that animal experimentation must stop. Experiments could go on, however, without pain or torture to the animal, and the whole propaganda of antivivisection was based on incorrect facts and ignorance. Mr. Herbert Brown, on the other hand, said that during the past half-century a steady increase had taken place in the number of animals used for experiments. The great majority of these were done without anaesthetics, and although many of these were simple inoculations, he held that even inoculations could be followed by great suffering. He expressed the opinion that experiments on animals had frequently led Lord Lister astray. He also questioned the benefits derived from experiments, and quoted opinions in support of his contentions.

GIFFORD LECTURES IN GLASGOW.

In his seventh Gifford lecture at the University of Glasgow Dr. J. S. Haldane spoke on animistic interpretations of conscious behaviour. From time immemorial, he said, the distinguishing feature of conscious behaviour was supposed to be due to the presence of an independent soul within the body. The development of this idea had proceeded side by side with the development of the Newtonian conception of the physical world. The supposed independent soul had turned out now to be something which was dependent in every respect on the physical body and environment, and their influences could not be separated. The animistic conception of a physical body guided by an independently existing soul could no longer be upheld, for such a conception would amount to a denial of the validity of the law of conservation of energy. They were bound to conclude that all psychical phenomena were mechanically determined. In his eighth lecture Dr. Haldane discussed the mechanistic and biological interpretations. In mediaeval and modern times mechanistic conceptions of conscious behaviour had been to a large extent suppressed by ecclesiastical or State authority. They were commonly associated with atheism, although that was not always the case. Some forms of theology had come very close to mechanistic interpretation in their conception of human behaviour. That conception had been a natural revolt from animism, and the mechanistic interpretation of conscious behaviour appeared at its strongest when pitted against animism, just as the animistic interpretation also appeared at its best when pitted against vitalism. The objection to the mechanistic interpretation as commonly applied was that it made no attempt to give any physico-chemical explanation of the fact of consciousness. It simply treated consciousness as a completely mysterious accompaniment of physiological phenomena, which occurred in the central nervous system of higher animals. Intermediate between mechanistic and animistic interpretations of conscious experience was another mode of interpretation which might be called biological. This was represented in the writings of Leibnitz and Bergson, and had recently been given in a clear-cut form by General Smuts in a book known as *Holism and Evolution*. The lecturer agreed with the conception held by General Smuts, although he differed from the latter's treatment of the personality.

GLASGOW WESTERN INFIRMARY.

The David Elder Infirmary at Govan, which is an adjunct to the Glasgow Western Infirmary, is nearing completion, and will, it is expected, be ready for occupation in the course of the next few months. The accommodation afforded by this new building would help to reduce the waiting list at the Western Infirmary, where 45,000 patients were treated during 1926. Despite the adverse industrial conditions of last year subscriptions from employees amounted to £20,648, a decrease of only £3,000 on the previous year. Legacies had enabled the managers not only to clear off a deficit on the maintenance account amounting to about £15,000, but to carry about £3,000 to capital account.

CHALMERS HOSPITAL, EDINBURGH.

The annual report by the directors of Chalmers Hospital showed that the number of patients treated during the year was 518 in the public wards and 407 in the private wards, making a total of 925. The ordinary income had exceeded the ordinary expenditure by £28. For some years there had been an increasing necessity for accommodation for the study and training of nurses, and it was now decided at a cost of £1,500 to build an additional lecture room and study. It was also decided to build an open-air balcony attached to the male public ward.

CENTRAL MIDWIVES BOARD FOR SCOTLAND.

The examination of the Central Midwives Board for Scotland, held simultaneously in Edinburgh, Glasgow, and Dundee, has just concluded, with the following results: Out of 98 candidates who appeared for the examination, 90 passed. Of the successful candidates, 14 were trained at the Royal Maternity Hospital, Edinburgh, 31 at the Royal Maternity Hospital, Glasgow, 3 at the Maternity Hospital, Aberdeen, 9 at the Maternity Hospital, Dundee, 9 at the Queen Victoria Jubilee Institute, Edinburgh, and the remainder at various recognized institutions. At a meeting of the Board for the election of office-bearers

Dr. Haig Ferguson was unanimously re-elected chairman. Sir Archibald Buchan-Hepburn, Bt., was re-elected deputy-chairman and convener of the finance committee. The meeting appointed other committees and examiners, and approved, subject to inspection by the Board, the list of recognized institutions, with the teachers attached thereto, for the training of midwifery nurses.

EDINBURGH SOCIETY FOR THE RELIEF OF DESTITUTE SICK.

The annual report of the Edinburgh Society for the Relief of the Destitute Sick showed that the number of applications for relief during 1926 had not been notably affected by the industrial position, but the weekly expenditure on each beneficiary had on the average been increased during the coal dispute. The new cases assisted numbered 1,085, as compared with 1,238 in the previous year; the number of visits paid was 7,350, as compared with 8,100 in the previous year; and the total sum expended in relief of the sick poor had been £2,960, as compared with £3,123. The Lord Provost, who was in the chair at the annual meeting, congratulated the directors on their successful work among the destitute sick of the city, which had been carried on for over 140 years. The object of the society was to assist families over temporary difficulties when the breadwinner was laid aside by illness, and though legislation had done much to insure working people against accident and illness, there was still a wide field for the society's activities.

Ireland.

ORTHOPAEDIC WORK IN DUBLIN.

At the annual meeting of the Incorporated Orthopaedic Hospital, Dublin, when Lord Glenavy was in the chair, Dr. Kirkpatrick submitted the report, in the course of which it was stated that the number of patients treated during the year was 1,522 (1,347 extern and 175 in-patients). The open-air ward in the garden, with sixteen beds, had been in existence for more than twenty years, and was the pioneer example of open-air treatment in Ireland. The waiting list of patients for admission had steadily increased to 75. This showed the urgent need for increasing the number of beds available, a total of 150 at least being necessary. This expansion to 150 beds should be accomplished by obtaining an open-air home or hospital in the country, in accordance with the most modern orthopaedic principles. For this object a fund had already been opened. A most valuable scheme had been formulated by the Rotary Club for undertaking the after-care of some of the patients. The governors offered their thanks to, among others, the Rotary Club, to Lady Chance, to the officials of the Land Commission, to the United Free Church of Scotland, and to many others for gifts of money and toys. His Excellency the Governor-General, in moving the adoption of the report and a resolution stating that the hospital was worthy of public support, expressed his congratulations on the escape from death or injury of the nurses, medical officers, and children in the calamity that had befallen the building in the great storm. He thought all would feel that there was imposed upon them an additional duty because of the effects of this occurrence on the funds of the hospital. As an old friend of the late Mr. Joseph Mooney, he felt grateful that his services to the institution had not been forgotten, and that in the report a tribute of recognition had been paid him and his family for the devotion which he had given to the great institution. Mr. Mooney was a man of exceptional virtue and merit, and it was not until his death that he (the Governor-General) was acquainted with all his virtuous activities. In visiting the hospital that day he had the pleasure and satisfaction of going through some of the wards, and he would express his thanks to the matron, officers, and doctors of the institution for the happiness which glowed on the faces of the children. He detected among the children a feeling that they were at home—and in an affectionate and kindly home—and, suffering as they were, cheerfulness was the best proof, not merely of their docility, but of the kindness which they were shown by the sisters and doctors. Dr. Haughton, whose zeal was remarkable, had told him that during the last two years 3,098 crippled children had been attended to and benefited. He would like the public to take into their minds what that meant—3,000 children benefited, and some of them, he might say, altogether cured. They read in the gospel of the miracles wrought by our Lord—and was it not something to think that to-day Christian charity, flowing through the minds and souls and skill of persons like those who had charge of that institution, had been able to give healing and benefit to 3,000 children? A way of appreciating that noble institution was that those who had wealth should send from time to time some donation or give it some benefit in their wills. He proposed himself to give a cheque for £50 to the institution because of the calamity which had befallen it, and there were few who could not, by a small donation, help in the great work which that institution was performing. Mr. E. D. MacLaughlin, who seconded, said the hospital had been honoured last year and the year before by visits from Sir Robert Jones, who delivered several addresses, and impressed the enormous advantage of open air and sunshine in the treatment of orthopaedic cases. There was at Cappagh a magnificent open-air establishment approaching completion, which would have accommodation for 200 beds devoted to the cases of crippled children. It was imperative on the hospital some time or other to leave its present building and emigrate to the country. The only obstacle to the move was want of money. The governors of the National Hospital for Children, Harcourt Street, Dublin, had decided to move it to the country, and had suggested that the Orthopaedic Hospital should join forces with them and set up a conjoint establishment. There were, however, difficulties, the main one being that the Orthopaedic Hospital might not get all the accommodation it wanted. The suggestion was receiving the very careful and sympathetic attention of the medical and surgical staff and of the governors. Referring to the damage done by the storm, Mr. MacLaughlin said that the matron and the nursing staff had displayed remarkable coolness and courage. Thanks were due to them, to the Civic Guard and the soldiers, and to the students of the College of Science, who had rushed in and given assistance. The cost of repairs might be anything from £700 to £1,000. He expressed the gratitude of all present to the Governor-General for attending.

ROYAL COLLEGE OF SURGEONS IN IRELAND.

The Charter Day dinner of the Royal College of Surgeons in Ireland was held on February 19th, when the guests included the Governor-General of the Irish Free State, the Vice-Chancellors of the Universities of Dublin and Belfast, the Chief Justice, the President of the University of Dublin, and some thirty medical practitioners from Belfast. The President, Mr. Andrew Fullerton, proposing the health of the Governor-General, referred to the great interest which he had taken in the Royal College of Surgeons. In his reply, the Governor-General congratulated the President on the support received from the two Universities of Dublin and Belfast. In medicine and surgery such geographical considerations as longitude and latitude seemed to have been abolished, and boundary differences did not arise. The medical profession differed from that of politics in that a preliminary diploma was required before practice was allowed, whereas politicians elected by universal suffrage could recommend both evil and good courses for their country without previous training or personal responsibility. He hoped that this bond of union between North and South Ireland would tend to dissipate prejudice, intensify mutual acquaintance, and forward the conjoint interests of the whole country.

INSPECTION OF DOWN COUNTY MENTAL HOSPITAL.

The Prime Minister of Northern Ireland, Lord Craigavon, accompanied by Sir Dawson Bates, the Minister of Home Affairs, in the course of a tour of Northern Ireland visited Downpatrick and inspected the Down County Mental Hospital on February 7th. He was received by the chairman, Senator J. Hill Dickson, who expressed his satisfaction that the recommendations of the recent Royal Commission on Lunacy in England had been previously adopted in the hospital. The economy in administration

and efficiency of treatment were largely due to Dr. M. J. Nolan, the resident medical superintendent, who had held office as president of the Royal Medico-Psychological Association of Great Britain and Ireland, and was this year president of the Ulster Medical Society. Lord Craigavon explained that the purpose of his visit was to establish close co-operation between the Government and those who were in charge of the administration of public institutions. After an extended visit to the different departments of the hospital he expressed his strong approval of the way in which the work was being carried out.

England and Wales.

Manchester Post-Graduate Courses.

The Manchester Royal Infirmary post-graduate lectures, which were revived at the close of the war, and have received a good amount of support among practitioners in the district, are to be continued in the coming session, March 1st to May 27th. On Tuesdays lectures on various subjects, and on Fridays ward demonstrations of cases, are to be given. With the next academic year (1927-28), commencing in September, it is hoped to start university post-graduate courses, most of which are for those in the district and outside who can devote their whole time to the work for a shorter or longer period, though some are being specially arranged as part-time courses in subjects of interest to those in public health services. A prospectus of these courses will be issued shortly. Manchester has an untapped wealth of clinical material for such post-graduate instruction, and all the leading hospitals of the town are working with the University to make this scheme a success.

Seamen's Hospital Society.

H.R.H. Prince George, acting for his brother, the Duke of York, who is president of the society, took the chair at the annual court of governors of the Seamen's Hospital Society on February 21st, when the 106th annual report was presented. It showed that the number of in-patients treated during the year at the Dreadnought Hospital, Greenwich, and the five other institutions under the management of the society, was 5,381, and the number of out-patients was 22,883. Prince George said that the hospitals of the society were never closed to a sick sailor. The motor ambulance would fetch him from any dock, and he received the services of the eminent physicians and surgeons who were on the honorary staff of the hospitals. They attended him voluntarily, with that generous expenditure of time and skill which was characteristic of the medical profession. The patient might or might not go to the Dreadnought Hospital itself. He might be taken to the Tilbury Dock Hospital, the Albert Dock Hospital, the Hospital for Tropical Diseases, or the King George's Sanatorium for Tuberculous Seamen. When he was convalescent he would go to the Angas Home in Kent, with its 300 beds. He would be nursed back to health if that was possible at all—not half-way to health, but to a condition in which he was able to return to his employment. Prince George added that, as himself a sailor lately back from the East, the work the hospital did for tropical diseases was particularly interesting to him; such diseases called for highly specialized medical knowledge, which the society, through its medical staff, made available for the sailor in London. The impression he had formed of the Dreadnought Hospital on a recent visit was that it would satisfy the commander of a battleship, which was the highest praise an officer of the navy could give to a shoregoing establishment. Sir Arthur W. Clarke, chairman of the society, said that Tilbury Hospital, the latest addition to the institutions overlooked by the society, was now established with sixty beds, all fully occupied. At the Bramshott sanatorium a light unit was being provided. The commitments of the society required £80,000 to be collected every year. Sir Burton Chadwick, M.P., Parliamentary Secretary to the Board of Trade, and Sir I. Hamilton Benn made speeches in which they paid tribute to the merchant seaman and the hospital work done on his behalf, and a vote of thanks to Prince George for presiding was proposed by Dr. C. E. Sundell, senior physician at the Dreadnought Hospital, and seconded by Sir George Hume, chairman of the London County Council.

The Smoke Abatement Act, 1926.

Further reduction of the smoke evil is expected to follow the coming into operation on July 1st of the Public Health (Smoke Abatement) Act, 1926, to which, while under consideration in the House of Commons, we have previously referred. The Ministry of Health has now issued a circular (759) to county councils and sanitary authorities in England and Wales summarizing the Act, and suggesting how the new powers vested in local authorities may be wisely used. Special courses of training are already available for officials responsible for the abatement of smoke nuisances, and it is hoped that an increasing number of officers will attend. Regional committees are recommended in areas where the smoke problem is common to a number of local authorities, so as to secure uniformity of administration, fuller investigation of the problem, more thorough co-operation with industrial interest, and a higher standard in administration. The Minister advises that by-laws should be made in every considerable industrial district defining a nuisance under this Act; and that, in the absence of exceptional circumstances, the aim should be to legislate against the emission of black smoke for two minutes in the aggregate within any continuous period of thirty minutes. The production of smoke by private dwellings is not yet brought within the scope of the Act, but the Minister suggests that those concerned in building new houses should be encouraged to install heating and cooking arrangements which will reduce the amount of smoke. Care should also be taken to reduce the needless output of smoke from old dwellings.

Consulting Dental Surgeon to the London County Council.

An unusual course has been taken in the appointment of consulting dental surgeon (part-time) to the London County Council, a post rendered vacant by the recent death of Mr. Edward Wallis. The Establishment Committee, in making its recommendation, states that the consulting dental surgeon is required to advise respecting the dental treatment of school children, and his duties include the general supervision of the dental treatment centres. It is necessary that the officer holding this position should not only have a wide knowledge of dentistry, but should also be experienced in organization, and, if possible, be connected with one of the large dental schools, and thus be in touch with the latest aspects of dental research and knowledge. An appointment of this character is considered to require qualifications so exceptional as to justify a departure from the usual method of obtaining applications by public advertisement. The committee therefore invited an application from Mr. Alexander Livingston, M.B., Ch.B., M.D.S.Liverpool, director of dental studies at the school of dental surgery, King's College Hospital. It is considered that his experience and qualifications render him eminently suitable for the appointment, and therefore Mr. Livingston's is the only name put forward. The salary attaching to the appointment is £300 a year (based on pre-war conditions, and at present, with temporary additions, amounting to £388); the holder is required to devote five half-days a week to the Council service.

Leicester Medical Service.

The board of management of the Leicester Public Medical Service in its report for 1926—presented to the annual meeting on February 15th—states that the number of subscribers to the various sections of the service has increased, and the capitation fee to acting members of the service for attendance on subscribers, who were not State-insured persons, remained the same as during the previous year in spite of the unsettled industrial conditions which had affected the receipts. The number of prescriptions dispensed was fewer than in 1926. A radiological and electrotherapeutical department was inaugurated in connexion with the service during the year, and the dental depart-

ment was considerably extended by an arrangement with a large panel of dentists to give dental treatment to subscribers to the service on payment of moderate fees. The benevolent fund to assist uninsured persons in reduced circumstances to purchase insulin at a reduced cost proved very useful in a number of cases. A revised edition of the *Leicester Pharmacopoeia* was issued by the drug committee of the service during the year. At the same meeting the report of the committee of the Leicester subdivision of the Union of Medical Practitioners was presented, and it was stated that the scheme of collective locumtenencies during holidays or sickness had been successfully continued.

ROYAL DEVON AND EXETER HOSPITAL.

Improvements introduced during 1926 at the Royal Devon and Exeter Hospital included the allocation of a ward for maternity cases, but more accommodation of this kind is contemplated to meet the increasing demand. Additional separation wards have been arranged for tonsil and adenoid cases, and new fittings and apparatus have been installed in the operating theatre and the x-ray and pathological departments. During the present year it is hoped to establish a new dispensary, and to make various structural and administrative improvements. The inauguration of a scheme of pensions for the nursing staff is under consideration. The number of in-patients admitted during 1926 was 3,043, and of new out-patients 6,670; 2,350 surgical operations were performed, as compared with 1,896 in the previous year. To cope with the increasing work the resident medical staff has been increased to four, the nursing staff has been augmented, and a second masseuse has been appointed. In spite of the depression due to the coal dispute, the ordinary income increased by £998. The receipt of a legacy of over £15,000 enabled the balance of the building account to be paid off and a sum of £9,000 to be invested.

ST. MARK'S HOSPITAL, LONDON.

Presiding at the annual meeting of the St. Mark's Hospital, London, on February 18th, the Lord Mayor stated that the out-patient attendances had increased from 3,951 in 1923 to 5,956 in 1926. The number of in-patients admitted was 707, and the number of new out-patients was 1,522. The new wing of the hospital, which was being erected, would provide twenty-four more beds, and the plan of extension included the provision of a private ward for patients of limited means. Sir Charles Gordon-Watson said that owing to the fact that St. Mark's Hospital, with only one other hospital, was devoted to the treatment of cancer of the rectum, it received patients from all over the kingdom and was well known on the Continent and in the United States. Patients whose condition presented special difficulty and complexity tended to gravitate to St. Mark's Hospital, as also did surgeons who specialized in this direction. A gift of £500 was promised towards the £5,000 still required for the extension fund.

Correspondence.

LEPROSY: ITS TRANSMISSION AND TREATMENT.

SIR,—I have read in the BRITISH MEDICAL JOURNAL of January 1st (p. 40) letters by Dr. Hasson and Dr. Graham Little, in which, *inter alia*, they say that in their experience chaulmoogra oil has not been of much use in the treatment and cure of leprosy. With this opinion I concur. Some time ago Sir Leonard Rogers appealed for funds to cure leprosy. I wrote to him saying that though I thought his object a good one I was afraid he would be disappointed in the results of his treatment with chaulmoogra oil.

The two kinds of leprosy, the anaesthetic or nerve leprosy, and the nodular or tubercular leprosy, though due to the same bacillus, are so different in appearance and symptoms and require such a great difference in treatment that they should be classed as different diseases. The tubercle bacillus causes phthisis and lupus, two diseases not more different than anaesthetic and tubercular leprosy, and yet no one would treat phthisis and lupus in the same way. So that what may be beneficial in one form of leprosy may not be of any use in the other. In the anaesthetic form of leprosy, when the patient consults his medical man for "neuritis," the mischief has usually been done. The bacillus of leprosy causes an inflammation within the nerve sheath, and as the sheath is dense and tough the nerve fibres are destroyed by compression. Elsewhere I have said that, though I have had no opportunity of trying it, I feel sure that by making a linear incision in the nerve sheath at the affected part, the tension may be removed and the nerve saved. The nerves as a rule are not affected in their whole length, but only at certain points corresponding to the joints where the thickened nerves may be readily detected.

For these anaesthetic cases no treatment by medication is of any avail, for no medical skill or treatment can restore a destroyed nerve. In my *Handbook on Leprosy*, published in 1895, I pointed out that the anaesthetic form of leprosy started as neuritis, which lasted for about four years. By this time the bacillus has done its deadly work and has been destroyed in the debris. After this the patient is not a leper but is suffering from destroyed nerves, which lead to the terrible deformities which we associate with this form of leprosy. In the tubercular form of leprosy chaulmoogra oil is useful, but only in the very earliest stages of the disease. The drug has to be administered in large doses, and as it is most unpalatable this causes much trouble. I have tried many methods, but the one I have found the best is as follows:

Make up two bottles of the oil, 10 ounces of each. Colour the oil in one bottle with oil of lavender and use this as a liniment. The whole skin from top to toe has to be rubbed with the oil every day. The internal administration of the oil is a difficulty which can only be overcome by patience and perseverance. Start with five drops of the oil three times a day. The next day give ten drops three times a day. Gradually increase the dose by five drops every day until 120 drops are reached, which is the maximum dose I have used. If at any time the patient rejects the oil the whole process must be repeated. What with the inunction and this large dose of the oil the skin exudes the oil from every pore, and then one sees the good effect of the oil, if it does any good.

I once spoke to Professor Koch about the treatment of leprosy by vaccine, which could be extracted, I think, from the blood of cured lepers. He thought the idea good, but was afraid there would not be enough serum obtainable in this way to be of practical use, but I feel sure that if such a serum were of benefit to the sufferers there would be no lack of volunteers to supply the serum.

After a careful study of the disease and its bacilli I have come to the conclusion that the human body is not the natural habitat of the leprosy bacillus, but that the bodies of certain fish are.

If this is correct would it not be possible to obtain the bacilli from the fish and cultivate them, for in the fish, without producing any disease, the bacilli grow to an enormous size and very abundantly? In my book above mentioned I show two photographs of lepers before and after an attack of erysipelas, which produced a marked improvement in their condition. This one experiment shows that the leper can be cured by proper treatment, and I think a scheme of treatment based upon the action of erysipelas on the disease would be justified.—I am, etc.,

Capetown, Jan. 26th. S. P. IMPEY, M.D.

THE MENTAL DEFICIENCY BILL OF 1926.

SIR,—Will you allow me to reply to a few of the criticisms by Dr. Tredgold in his letter to you of February 5th (p. 259), in order that I may try to make clear to him and your readers that my chief reason for discussing this subject is that any revision of the existing "definitions" in the Act of 1913 should not be confined merely to such difficulties as have been already found in working that Act, but should contemplate the possibility of some further modification of the present legislation relating to the matter of the care and control of mentally affected persons generally, whether grouped as "insane" (that is, of diseased mind) or as "defective" (that is, of imperfectly developed mind). I intend by this the *unification* of the Acts regarding "*lunacy*" and "*mental deficiency*" respectively.

Were it not for the fact that a noticeable number of criminals come under these headings, and the nature of their cases is frequently disputed in law courts, I should lay somewhat less stress on my present contention. But it is a fact that the recognition of the importance of a better form of certification of persons deemed to be mentally affected did contribute largely to that desire for further legislation which occasioned the setting up of a Royal Commission, and, later, the passing of the Act of 1913.

It may be argued, of course, and indeed has been argued, that "mentally defective" criminals or any other "mentally defective" persons could be certified under the existing Lunacy Act, but it has been fully shown, since the Royal Commission reported, and up to the present date, nearly twenty years later, that medical experts do not thus certify them. And cases sometimes arise when medical witnesses, disagreeing as to whether a person charged with crime should be classed as "defective" or "insane," practically leave the court helpless, and a risk is run of a sane criminal being confined in an asylum. I do not believe that much, if any, risk is now run of an insane or a plainly defective person being convicted and awarded a severe sentence.

It must not be forgotten that there is now a rapidly growing tendency, especially in the United States and in England (I do not include Scotland or Ireland, lest I should err), to regard habitual and other criminals generally as mentally defective or deranged, and thus to teach or imply that they are "irresponsible" and should be treated as patients rather than criminals. I will not ask to occupy your space by illustrating this statement, but merely introduce it crudely for the sake of making my meaning clear. I am certainly not denying that there are several cases in which this plea may be sound and just in all its aspects; but to assume the truth of it generally, or in the majority of cases, would be, in my judgement, a grave error, against which the law should be carefully guarded.

With regard to one of Dr. Tredgold's criticisms, I wish to emphasize that I have not anywhere expressed, nor do I hold, the view that any new bill concerning this subject should not include adults. That opinion was expressed, not by myself, but by another writer elsewhere. It was merely mentioned by me as an instance of a popular misconception leading to the popular objection to measures of "control" generally. My own view is, of course, that any bill whatever that may be brought forward must, for any practical purpose, include not only adolescents, but adults also. Although I hold that the definition of "mental deficiency" approved by Dr. Tredgold would be inadequate to deal with the needs of any such future bill as I deem desirable, I confess to him my plain error in using such a term as "complete adolescence" in my attempt to improve upon the proposed definition: this attempt might more appropriately have ended at the words "observed subsequently." But I would now withdraw my suggested improvement altogether as not relevant to my main object.

I am of the opinion, since cases of any kind of mental affection often require control for the first time at an adult age, no short or strictly exclusive *definition* of the origin or cause of such affections should be laid down in a statutory declaration. I do not think that among the many cases which are subjects of various grades of mental feebleness, and come under medical inquiry for legal purposes, any medical witness should be called upon to state definitely that such and such an adolescent or adult is or is not suffering "from incomplete development of mind, either innate or induced after birth by disease, injury, or other cause." Rather should the medical witness be asked and encouraged to give his opinion clearly in such case, stating in his own words what he has observed, and should be allowed to express his opinion freely as to what kind of treatment—penal, medical, or otherwise—would be most appropriate.

Thoroughly watertight *definitions* are mostly very difficult to frame, and wellnigh impossible when it comes to framing one in the sphere of mental functioning. Thus when used in cases of criminal action they would probably be the occasion of a greater number of practically "responsible" criminals escaping the gaol or even the gallows than most medico-psychologists, however they might differ on many questions, would see with approval.—I am, etc.,

London, W.2, Feb. 17th. H. BRYAN DONKIN.

THE MODERN TREATMENT OF HERNIA.

SIR,—May I be allowed to make a few observations and criticisms on the remarks of Mr. John T. Morrison on this subject.

Undoubtedly pedicled sutures cut from the external oblique are of the greatest value in most cases of hernioplasty. This idea, however, is not new, and the technique has probably been carried out by more surgeons than may appear likely from a perusal of the literature. McArthur of Chicago in 1901 was probably the pioneer in this direction, and both McEachern and Adair in 1924 redescribed the procedure. Wainschenker of Czitomir commenced in 1923 the practice of stitching the conjoined tendon to Poupart's ligament by pedicled strips torn from each side of the external aponeurosis. In two years 125 cases were operated on by this method with only one recurrence. In order to facilitate the manipulation of this short suture I attach a "loop thread" to the head of the fascial strip.

I disagree with the practice of attempting to unite the conjoined tendon to Poupart's ligament. The observations of Oudard and Jean (1922) and the experiments of Gallie and Lemesurier, Seelig and Chouke and Koontz (1926) all show how difficult it is to obtain any permanent union from stitching muscle to fascia.

In the operation which I have now performed 201 times in the past two years, I take a flap from the inner side of the external aponeurosis of sufficient size to cover in the weak posterior wall of the canal. This is stitched to Poupart's ligament by a narrow pedicled strip taken from the opposite side.

The full details have now been published in a little book, *Hernia and Hernioplasty* (London: Lewis and Co.).—I am, etc.,

London, Feb. 19th. ERNEST COWELL.

SIR,—My attention has just been drawn to the fact that the method described by me in my letter (BRITISH MEDICAL JOURNAL, February 19th, p. 353) covers ground already somewhat fully dealt with. In 1904 Professor Blair Bell described a method of making use of autogenous fascial sutures from neighbouring aponeurosis (BRITISH MEDICAL JOURNAL, ii, 1145). In 1901 also Dr. L. L. McArthur described what is essentially identical with the technique I use. I need hardly say that my work was done in entire ignorance of both of these contributions.

Perhaps my letter may not be altogether useless if it serves to draw attention to what I consider a valuable adjunct to the surgeon's armoury in dealing with difficult cases of hernia.—I am, etc.,

Liverpool, Feb. 21st. JOHN T. MORRISON.

SIR,—A letter from Mr. John Morrison (JOURNAL, February 19th, p. 353) rightly draws attention to the value of fascial sutures derived from the external oblique aponeurosis in dealing with some of the more difficult cases of hernia. I cannot agree, however, that this procedure can ever be substituted for "Gallie's operation" proper. It was of the "exceptionally severe cases" that I was writing, and for these the more elaborate operation is necessary, as it is impossible to obtain in any other way enough material for the sutures. I should, perhaps, have referred to the operation described by Mr. Morrison, but I regard it only as an alternative to the still simpler operation (described in my article) in which a flap from the internal oblique aponeurosis is used to form a new floor for the inguinal canal.—I am, etc.,

London, Feb. 20th. GEOFFREY KEYNES.

POST-GRADUATE TOUR TO AMERICA.

SIR,—May I remind the surgical members of the profession of the proposed post-graduate tour in the United States of America and Canada which is now being organized by the Surgical Section of the Royal Society of Medicine? The details have already been set forth in your issue of February 12th.

It has been found necessary to alter the date of departure, which has now been fixed for August 20th. This alteration has been made partly to avoid interfering with the British Medical Association meeting, and also for the reason that more American surgeons of eminence will, by that time, have returned from their holidays.

The tour has been arranged to give surgeons in this country an opportunity of seeing the work of some of the important surgical clinics in the United States and Canada, at a reasonable cost, and with the minimum of time and personal trouble. Should the numbers exceed one hundred a special train for the party will be provided and the Cunard Company will send a travelling courier.

The organizers hope that this invitation will meet with an adequate response and that the members of the tour will compriso a representative body of British surgeons.—I am, etc.,

Wimpole Street, W.1, Feb. 22nd. V. WARREN LOW, President of the Section of Surgery of the Royal Society of Medicine.

R.A.F.M.S.

SIR,—The advantages and disadvantages of a career in the medical branches of the armed forces of the Crown have of recent years been brought much to the fore, and the firm front taken by the British Medical Association on certain questions has been of the greatest value. As a result of recent financial and other improvements, I understand that the services have, as a whole, again received the qualified blessing of the Association.

Although much has been heard of the Army and Navy, the Royal Air Force has passed largely unnoticed, doubtless owing to the fact that it is of tender age and not so well known in medical circles. The most useful information is not always obtainable from official sources, and it may serve a useful purpose to note some points not set forth at Air Ministry interviews.

Air stations at home, compared with army stations, are, on the average, unutterably dreary as to site. The amount of medical work is slight, but the necessity for remaining on duty while flying is in progress by day and night is inexpressibly tedious, as medical officers are far too frequently single-handed. Provision for housing married officers is seldom made, and they have to live where they can. A motor car becomes a necessity.

Hospitals are few, and scant encouragement is given to officers to develop along the line of their own special interests. Study leave and ordinary leave are both difficult to obtain. Transfers are never-ending. Foreign service invariably means Iraq sooner or later, and the married man should know that ladies are not allowed to land even in the cold weather. He must go alone.

The status of the medical branch within the Royal Air Force is not yet satisfactory, doubtless owing to the shortage of senior officers of real standing. It should also be realized that it is advisable to rely solely on those prospects which are clearly laid down in printed regulations, and it is further necessary to remember that the Royal Air Force as a whole does not confer the social seal of the older services. Candidates for the services would do well to approach the R.A.F.M.S. with special caution.

A word of warning is needed for officers of other services who may contemplate a transfer. Owing to the extraordinary system, or rather lack of system, of promotion which has been in rogue, they are likely to find themselves, even after promotion, permanently junior to a number of men of considerably less total service. This is entirely opposed to the recognized principles of transfer, and is a pitfall for the unwary, for the discovery will probably not be made until too late. It is hardly necessary to say that the facts are unlikely to be pointed out officially.

This may well be regarded as a serious matter, for its effect both on the individual and on the service needs no elaboration.—I am, etc.,

LUX IN TENEBRIS.

ANAEROBIC STREPTOCOCCI.

SIR,—The attention Dr. C. E. Jenkins draws to anaerobic streptococci (February 5th, 1927, p. 231) emphasizes an interesting point in regular laboratory routine—that is, the importance of more thorough anaerobic work in all cases under bacteriological investigation. For many years it has been a routine arrangement that all specimens under bacteriological examination, such as abscess, dental, sinus, and particularly intestinal, urinary, and uterine cultures, should be treated anaerobically as well as aerobically, and the result of this has been that in a considerable proportion of such examinations streptococci particularly are recovered anaerobically when none have appeared in aerobic cultures; further, varying species of streptococci are sometimes more definitely isolated by these methods than by the aerobic cultures alone.

Of particular interest is the isolation of cutaneous organisms in psoriasis and other chronic skin infections, which on aerobic culture will frequently only give evidence of staphylococci, but by a careful anaerobic technique organisms of more obvious pathogenic importance are not infrequently isolated. These have included organisms of the streptococcal and diphtheroid groups.

Of equal interest is the use of anaerobic cultures of tissue specimens, such as those removed from joints, or periarticular material obtained from chronic rheumatic infections, etc. In these the organisms' natural habitat is anaerobic, and it seems strange that those searching for evidence of infection in such tissues do not more extensively use effective anaerobic culture methods, for in many cases it is only by such methods that any positive cultural results will be obtained.

Dr. Jenkins does not refer to the work of the late Dr. Ford Robertson, whose special anaerobic technique is probably the most useful and satisfactory yet introduced, and it has been the adoption of his methods which has made it possible to obtain, in general routine bacteriological examinations, the most satisfactory streptococcal cultures of obvious pathogenic importance from many specimens of various kinds. From personal experience one would agree that those who use an efficient anaerobic method, along with the ordinary aerobic cultivation, in the examination of clinical material, will not be disappointed with the improved results obtained, which make the extra trouble well worth while.

Particularly is this of importance if vaccine therapy is being contemplated as the result of the clinical investigation being carried out, for the immunizing response to vaccines prepared from such anaerobic cultures is frequently very much more satisfactory than when cultures obtained by aerobic methods only are employed. There are numerous instances of patients who have failed to show improvement on a vaccine prepared from aerobic cultures having later satisfactorily responded to one which includes organisms isolated anaerobically.—I am, etc.,

February 8th. E. CRONIN LOWE, M.B.E., M.B., B.S., Honorary Pathologist and Bacteriologist to the Southport Infirmary and the Eye and Ear Infirmary, Liverpool.

THE EFFECT OF CLOTHING ON THE BODY.

SIR,—In judging the effect of clothing on the body, the actions and reactions of the body itself have not been sufficiently considered. The temperature of the body is maintained at the level of about 98.4° F. by means of the immense chemical activity of the body cells. The heat thus produced is much greater than is necessary to keep the body at this temperature, and a big surplus has to be got rid of, but it must be eliminated slowly and evenly, without sudden changes. The chief methods are by respiration, and by the skin by radiation and evaporation.

By a dry skin, warmer than the surrounding air, the heat is radiated gently and regularly. The greater the difference of temperature between two objects, the greater and swifter is the exchange of heat and cold, so that, other things being equal, a cool skin parts with less heat, and more slowly, than does a warm one. Invisible perspiration is constantly going on, surrounding the body with a vapour which is warmer and damper than the outer air, but if the

skin is well ventilated this is removed as it forms, leaving the skin dry.

In this climate evaporation by sweating occurs when the body is in urgent need of getting rid of surplus heat, as during violent exertion. It also occurs when the sympathetic system is violently excited. Sweating is an "emergency exit" producing great and sudden loss of heat, and is followed by chill if the cause is not continued. In ordinary life no sweating should occur. A short run of a hundred yards to catch a train, or a round of golf, followed by sweating means that the person is unsuitably clothed. The skin should be as free from moisture after as before.

But clothing has been chosen which prevents aeration of the skin. The popular woollen undergarments, elastic and closely fitting, prevent the body vapour from being swept away; the film of warm damp air becomes warmer, denser, and damper; the body cannot discharge its surplus heat to an air cooler than itself, and has to resort to visible perspiration. Immediately the body loses heat at a rapid rate by evaporation, instead of by the slower and healthier method of radiation, its vitality is lowered by the sudden chill, and disease results.

In wearing wool next the skin the need of elimination of heat has been entirely lost sight of. This climate is not a cold one, but it is very windy; and when the skin is damp and warm, the wind, and especially the dry east wind, exerts a tremendous power of lowering the body temperature by evaporation. The body can keep itself warm if it is allowed to do so, but it is constantly being thwarted by the peculiar clothes demanded by civilization. In our desire to keep warm we destroy the innate power of the body to resist cold.—I am, etc.,

London, N.W.3, Feb. 14th. MARIAN THORNETT, F.R.C.S.I.

THE "NURSING MIRROR."

WE referred recently, in a leading article, to the *Nursing Times* as "the leading nursing journal," and in the following issue we gave full publicity to a letter from the proprietors of the *Nursing Mirror*. In order, however, to obviate any possibility of misunderstanding, we desire to say that we used the epithet "leading" solely on account of the official connexion of the *Nursing Times* with the College of Nursing, and we had no intention of representing the *Nursing Times* as a more important or more widely read paper than the *Nursing Mirror*, or of depreciating in any way the well established position and influence of the latter journal.

Obituary.

GEORGE ARTHUR PHILLIPS, M.R.C.S., J.P.,

Consulting Surgeon, Wallsall Hospital.

MR. G. A. PHILLIPS died at his home at Streetly, Staffs, on February 18th. Born at Whitwell, Herts, in June, 1849, he was the son of a doctor—George Marshall Phillips, M.R.C.S., who carried on active work into ripe old age and when about eighty years old acted as locumtenent to his son.

George Arthur Phillips was educated at Rossall and St. Bartholomew's Hospital, and in the early seventies, after obtaining the M.R.C.S.Eng. and L.S.A. diplomas, he settled in Walsall, where he speedily made a name for himself. Among the many activities crowded into his fifty years' association with the borough were, at various times, those of senior and afterwards consulting surgeon at the Walsall Hospital (of which he was a trustee, and where for many years he was a carver on Christmas Day), a certifying surgeon under the Factory Acts, a county court medical referee under the Workmen's Compensation Acts, local surgeon to the railway companies, medical officer to the Post Office and leading insurance societies, president of the Staffordshire Branch of the British Medical Association, examiner for the St. John Ambulance Association (he was also an honorary associate of the Order of the Hospital of St. John of Jerusalem), a governor of Queen Mary's Schools and vice-chairman for several years, a commissioner of taxes, chief consul for Staffordshire for the Cyclists' Touring Club, and a trustee of several charities, including Fishley and Bentley Hay.

But his public activities (writes the colleague to whom we owe the details of Mr. Phillips's career) were really his lesser activities. Where he chiefly shone was as the personal, private, family doctor—a type which seems to be becoming less and less apparent. He had a charm of manner which endeared him to all. It is no exaggeration to say that he carried with him, wherever he went, a ray of sunshine. Old ladies loved him, old gentlemen offered him glasses of port, which he refused—always was he a most abstemious man; young people beamed at him and became suddenly well at the behest of his cheery bidding. He was of the good old school. He believed in himself and he believed in everyone else—with a few exceptions. May he rest in peace. He was a very gallant gentleman, who kept a stiff upper lip when things went against him.

By the death of Sir JOHN UTTING, an ex-Lord Mayor and chairman of the Corporation Finance Committee, Liverpool has lost a distinguished citizen, an impressive, decorative, and valuable alderman, and a very popular man, who first earned affection as a practising physician. He was born in Norfolk in 1852, and received his medical education at Guy's Hospital. He obtained the diplomas M.R.C.S.Eng. in 1874 and the L.R.C.P.Ed. and L.M. in 1884, after spending three years as a ship surgeon. He settled in Liverpool at the age of 25, and rapidly established a large practice, while at the same time taking a keen interest in all matters of public health. He entered the city council in 1899, and did a large amount of work on the Port Sanitary and Hospitals Committee. As chairman of the committee for twenty years he contributed greatly to developments in sanitary science, and as chairman of the Liverpool University School of Hygiene he did equally valuable work. In the early years of the war he served in the R.A.M.C. as major on the staff of the 1st Western Military Hospital; he was demobilized in 1917 in order to become Lord Mayor of Liverpool. During his tenure of this office he was wonderfully successful in sustaining financial contributions to charitable institutions, while at the same time he raised over £80,000 for the Red Cross funds. In 1919 he became chairman of the Finance Committee of the Corporation, and in this position showed great capacity. In the following year he was created Commander of the Order of George I by the King of the Hellenes, and in 1921 the Red Cross medal of the 3rd Class Cruz Vermelha de Merito was presented to him by the President of the Portuguese Republic. He received the honour of knighthood in 1924.

By the unexpected death, on February 5th, of Dr. RICHARD RICHMOND of Wimbledon the medical profession has lost a member of the finest type; a man wholly devoted to his work and to the welfare of his patients, for whom no sacrifice of strength or comfort seemed to him to be too much. He was born at Kendal, and received his medical education at Edinburgh University, where he graduated M.B., C.M. in 1888, and proceeded M.D. in 1893. He then undertook a course of study at the Royal London Ophthalmic Hospital, Moorfields, and acquired the skill and interest in ophthalmology which he found very useful in his first practice at Great Bardfield in Essex, where he did quite a considerable amount of operating in eye cases. He moved to Wimbledon nearly thirty years ago, practising at first single-handed and afterwards in partnership with Drs. Bates and Newton. He was one of the honorary medical staff of the Wimbledon Hospital. He leaves a widow and four children; one son holds a commission in the R.A.M.C. and another is a medical student. A colleague writes: Dr. Richmond was an excellent all-round clinician, practical and resourceful in treatment. But the feature in his medical work which always especially struck the writer, who knew him well, was his determination, and his refusal in the case of patients to acknowledge failure or defeat. Unwearied on their behalf, always on the alert, and ready to try some fresh line of treatment, he was extremely happy in his measures, and his insight enabled him again and again to register marked successes in cases which had seemed unfavourable or hopeless.

Dr. JOHN FLETCHER PORTER of Upper Clapton died on February 17th, aged 54 years. He was the son of a clergyman, was educated at the Victoria University, Leeds, and at the London Hospital, and took the diploma of L.S.A. in 1897, and two years later graduated M.B.Lond. He had practised for many years in the East End of London, was physician to the Home Hospital for Women, Stoke Newington, medical officer to the Salvation Army Maternity Hospital and Homes, surgeon to the Linen and Woollen Drapers' Institute, and medical officer to the Post Office. In 1915 he was appointed president of the Special Army Medical Board for Neurasthenic Cases, and subsequently became Deputy Director of Medical Services under the Ministry of Pensions. He held the rank of major in the R.A.M.C. Dr. Porter was a well known Freemason, a member of the City Division of the British Medical Association, and a magistrate for the Tower Division. The honour of C.B.E. was conferred upon him for services rendered during the war. He married in 1901 and is survived by his widow and two daughters.

Sir KAILAS CHANDRA BOSE, C.I.E., died recently, aged 76, in Calcutta. He was educated at the Calcutta Medical College, and after taking his degree, fifty years ago, started practice in Calcutta. He was honorary physician to the Calcutta Medical College Hospital, and was a member of the governing body of the State Medical Faculty of Bengal. He had been of great assistance to the Calcutta School of Tropical Medicine and its attached hospital, by inducing some of his wealthy Indian patients, chiefly marwaris, to contribute liberally to the school. He found time for an immense amount of general public work in Calcutta. He was vice-president of the last Indian Medical Congress, delegate from Bengal to the All-India Sanitary Conference, president of the Calcutta Medical Club, and a member of the Plague Commission; for twenty-two years he was a member of the Calcutta municipality; he was also an honorary Presidency magistrate, and a Fellow of Calcutta University. In 1909 he received the gold medal of the Kaisar-i-Hind order, in 1910 he was decorated with the C.I.E., was knighted in 1916, and was given the O.B.E. in 1918. He leaves a widow, six sons, and three daughters.

Dr. WILLIAM JAMES CAIE of Bury St. Edmunds died on February 6th. He was the elder son of the late Rev. W. S. Caie, minister of the parish of Enzie, Banffshire, and after studying at the Universities of Aberdeen and Dublin, graduated M.A.Aberd. in 1895, and M.B., Ch.B. in 1900. He was prosector of anatomy in the University of Aberdeen, and served as resident surgeon and resident gynaecologist at the Aberdeen Royal Infirmary. He subsequently went to Bury St. Edmunds, where he joined Dr. Kilner in partnership. He was for over twenty years a member of the Bury St. Edmunds Town Council, held office as mayor of the borough for two terms (1923-25), and was appointed a Justice of the Peace. He was a member of the medical board of the West Suffolk Sanatorium, and medical officer of the Sir John James Charity. Dr. Caie was a member of the West Suffolk Division of the British Medical Association, and several papers by him on obstetric subjects were published in these columns. On the day of the funeral at Aberdeen a memorial service was held at St. Mary's Church, Bury St. Edmunds, which was attended by the mayor and a number of public officials and friends.

The death of Dr. WALTER P. SIMPSON, M.B., C.M., occurred on February 10th at his residence in Bathgate. He had been carrying out his professional duties as usual down to February 5th, and his death came as a shock to the public. Dr. Simpson was born at Edinburgh in 1869 and was a grand-nephew of the late Sir James Y. Simpson. After graduating at Edinburgh University in 1892 he became house-surgeon in the Royal Maternity Hospital, Edinburgh, and after holding several other minor appointments settled in Bathgate, taking over the practice of the late Dr. Tennant some twenty-nine years ago. In addition to the duties of a large practice Dr. Simpson took a great interest in all forms of sport, his favourite recreations being golf and curling. He was an enthusiastic member of the British Medical Association and was a keen Freemason, being twice elected to the chair of the lodge to which he belonged. He was unmarried.

An old friend of Dr. C. J. Harrison of Chelsea, of whose life a short account was given on February 19th (p. 357), desires us to add to what was then published some lines about Dr. Harrison as a sportsman and artist. He was an experienced yachtsman; within nine months of commencing golf his handicap was plus one; as a photographer he produced most artistic prints; he was a good woodcarver, and a past master with the lathe. Harrison, he adds, "excelled in anything he put his hand to; and inspired the greatest confidence in his patients."

Universities and Colleges.

UNIVERSITY OF OXFORD.

AT a congregation held on February 19th the following medical degrees were conferred:

D.M.—V. S. Hodson.
B.M.—D. A. Robertson, C. S. Broadbent, M. D. Bower.

UNIVERSITY OF CAMBRIDGE.

AT a congregation held on February 18th Dr. H. H. Dale, F.R.S., was appointed an elector to the Professorship of Physiology. The following medical degrees were conferred:

M.B., B.CHIR.—J. C. P. Grey, W. H. Palmer.
M.B.—R. W. Cuningham.
B.CHIR.—F. C. Roles, H. J. Heathcote.

UNIVERSITY OF LONDON.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

Division of Tropical Medicine and Hygiene.

THE following passed the school examination at the termination of the eighty-first session (October, 1926–February, 1927):

*H. W. Kumm (Duncan Medal), *P. H. Martin, *C. L. Bilderbeck, *B. Williamson, *E. S. Anthonisz, *S. G. Harrison, *H. M. Shelley, *N. P. Dalal, *L. W. Keays, T. B. M'Aleer, Young, W. Young, F. King, H. O. Newell, T Menon, N. R. Tadiwa Miller, I. J. Patel, S. T F. R. Lockhart, M. I J. H. Hislop, N. Vane J. S. Oliphant, J. H. Loganadan, P. L. Whig, E. Stuart-Taylor, E. C. A. Fristedt, M. M. Nolan, J. Pattis, F. M. Frost, Ou Koh Boo, K. A. Maclean.

*With distinction.

NATIONAL UNIVERSITY OF IRELAND.

AT a recent meeting the Senate had under consideration the reports of the examiners upon the results of the Pre-registration Examination in Physics and Chemistry, December, 1926, and the M.B., B.Ch., B.A.O. Degrees Examination, January, 1927, and awarded passes, honours, etc., in connexion therewith.

James M. O'Donovan, M.D., B.Ch., B.A.O., M.Sc., was appointed to the lectureship in medical jurisprudence at University College, Cork.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE remaining lectures of the course arranged by the Royal College of Surgeons of England include one on Monday, February 28th, by Mr. V. Zachary Cope on shock and collapse, with special reference to abdominal disease. Sir Arthur Keith's series of six lectures on recent researches carried out in the Museum will commence on Wednesday, March 2nd, and will be continued on Fridays, Mondays, and Wednesdays until March 14th. On Wednesday, March 16th, Dr. Hildred Carlill will lecture on simulation of surgical affections by hysteria, and on Friday, March 18th, Mr. R. St.Leger Brockman on the toxaemia of acute intestinal obstruction. The final lecture of the series will be delivered by Dr. Alfred Piney on hyperplasia and neoplasia in lymphatic tissue. The lectures will be delivered at 5 p.m.

Medical Notes in Parliament.

[FROM OUR PARLIAMENTARY CORRESPONDENT.]

AFTER hearing an announcement from the Foreign Secretary on Monday that an agreement regarding the status of the British settlement at Hankow had been signed with the Nationalist Government, the House of Commons spent the week on Supplementary Estimates, and on a bill whereby the Government proposed to indemnify Scottish parish councils for certain poor relief given, apparently illegally, to miners' families during last year's coal dispute.

Keen debates arose in the House of Commons on Supplementary Estimates for the Ministry of Health. These discussions centred round the allegation that, both in Scotland and in England, during the mining dispute, an unusual number of claims to benefit had been passed by medical practitioners under the National Health Insurance Act.

Experiments on Dogs.

As mentioned last week, a dogs' protection bill was introduced in the House of Commons by Sir Robert Gower. The bill has now been printed, and is backed by Colonel Moore, Mr. Macquisten, Captain Arthur Evans, Mr. Sexton, Mr. Thurtle, Mr. Radford, Mr. G. W. H. Jones, and Mr. Bromley. The bill has been put down for second reading on April 29th. The following is the text of the bill; its terms seem to be identical with those of bills brought in at various dates since 1920 in either House by Lord Banbury, Lieut.-Commander Kenworthy, and others.

A BILL to Prohibit the Vivisection of Dogs.

BE it enacted by the King's most Excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same, as follows:

1. *Prohibition of Painful Experiments on Dogs.*—Notwithstanding anything in the Cruelty to Animals Act, 1876 (hereinafter referred to as "the principal Act"), it shall be unlawful to perform any experiment of a nature calculated to give pain or disease to any dog for any purpose whatsoever, either with or without anæsthetics, and no person or place shall be licensed for the purpose of performing any such experiments.

2. *Penalties.*—Any person performing or assisting or taking part in performing any such experiment on any dog shall be guilty of an offence against the principal Act and punishable accordingly, and the provisions of this Act shall have effect as though they formed part of that Act.

3. *Short Title and Citation.*—This Act may be cited for all purposes as the Dogs' (Protection) Act, 1927, and the principal Act and this Act may be cited together as the Cruelty to Animals Acts, 1876 to 1927.

Medical Benefit during the Coal Dispute.

Scotland.

In Committee on the Civil Service Supplementary Estimates, in the House of Commons, on February 21st, Sir John Gilmour (Secretary for Scotland) presented a supplementary estimate for £322,295. This included £48,700 for maternity and child welfare, £20,000 for treatment of tuberculosis, and £95,000 for sickness, disablement, and maternity benefits (grant in aid). He said that the estimate for maternity and child welfare had been increased considerably owing to the very heavy claims during the recent troubles in the country. The cost of the treatment of tuberculosis also showed a serious increase, due in the main to the great rise in the price of fuel. Sickness, disablement, and maternity benefit had shown a rather alarming increase, which was causing considerable difficulty both to the Board of Health and to the medical profession in ascertaining the cause. He believed that the problem had arisen owing to the very abnormal circumstances, but that it did show some slackness of administration, and that there had been some lack of appreciation on the part of many of the medical men who had to deal with this admittedly difficult problem, would, he thought, be proved on investigation. At any rate, it was a matter which his department was taking up with those responsible. He could only say that during the period in which this enormous rise took place there was no real epidemic of sickness, or other difficulty which would have given rise to it. Equally, it was surprising to find how, on a certain date, this expenditure fell with great rapidity. It was quite clear that it had been, in the main, due to the abnormal circumstances and to the difficulty in which they might have placed many people in the administration of these services. It was a matter which the department was investigating, and of which, probably, further might be heard. An additional sum for the erection of another 1,000 steel houses was asked. These houses had proved, on experience, to commend themselves to the people.

Mr. W. Adamson, formerly Secretary for Scotland, said that experience showed that many of the criticisms levelled against steel houses were justified. People living in them said that, while they had no complaint against the accommodation provided, which was quite equal to that in the brick or stone houses, in the winter they were very much colder. He did not disagree with the increased estimate for maternity and child welfare, and said that if the Scottish Board of Health had been doing its duty during the trying times of the last nine months, it would have asked for a considerably larger sum. The Board objected to the town and parish councils doing so much for child welfare during the stoppage of last summer, and held up loans until the parish councils took on themselves the onus of making provision for child welfare. As a result the councils had been very heavily burdened. He would be very much surprised to find that the coal bill in the tuberculosis institutions had increased by the amount of the estimate for tuberculosis treatment. There must be some other explanation.

Dr. Shiels said that the remarks of the Secretary for Scotland suggested that the unfortunate doctors were to blame for the £93,000 now asked for for sickness, disability, and maternity benefit, and he would like the Secretary for Scotland either to justify or to retract this slur on an honourable profession. It seemed to him that another explanation was possible and more likely—namely, that the miners and their wives and children suffered owing to the coal stoppage and the lack of proper food, and that consequently there was an increase in sickness.

Dr. W. E. Elliot (Parliamentary Under Secretary for Health for Scotland) said that he had every desire to avoid the unpalatable conclusion that the £93,000 by which the sickness benefit had gone up was due to some extent to maladministration, but he could not entirely acquit the administration, particularly the medical administration of benefit, from having had a share in the very rapid rise in the curve of benefit in the months of the coal dispute. It was not due to a great increase in sickness. A great increase in sickness could not have been, and was not, purely a temporary thing. Some reflection of that increase would have been found in some of the other sickness curves, but none of the other vital statistic curves had moved up to an extent at all comparable. There was no corresponding peak in any of the curves except the benefit curve, and when a monetary curve moved like that, and all the vital curves remained down, the conclusion that this distortion was due to some other than a purely medical factor could not be avoided.

Dr. Shiels asked whether there had been any increase in sickness.

Dr. Elliot said that there was an increase in sickness benefit, but whether there was a corresponding increase in sickness or not was a question which was engaging the attention not only of the Board of Health in Scotland, but also of the Ministry of Health and of the British Medical Association and the Insurance Committees, all of which bodies were going into the matter very carefully at the present time. It would be premature to say more, but it was the case that there was a rise in the sickness benefit, but no corresponding rise took place in any of the epidemic diseases.

Dr. Shiels asked if the implied suggestion was that the doctors had certified people as being ill when they were not.

Dr. Elliot replied that he too, like Dr. Shiels, was a member of the medical profession; they could say things with regard to that profession which they would bitterly resent if said by laymen. All he would say was that the sickness benefit seemed certainly above the sickness rates. The statutory conditions with regard to sickness were undoubtedly relaxed in the period of the stoppage. Whether that was right or wrong—and conclusions could not now be drawn—it was the reason of the big rise in the benefits under this scheme.

Mr. James Stewart (formerly Under Secretary for Health for Scotland) said that he was rather astonished at Dr. Elliot's statement in regard to the medical profession. Dr. Elliot had implied that the doctors had connived at a state of affairs under which people had obtained sickness certificates in circumstances that were not creditable to them or to the doctors who granted the certificates. He then went on to say that this matter was under consideration by various bodies, including the Government and the medical profession. He (Mr. Stewart) thought that it would have been better if Dr. Elliot had left the remark as to the connivance of doctors until the investigation had been made and the charge proved or otherwise.

The vote was agreed to by 178—majority 100.

England and Wales.

In Committee of the House of Commons, on February 21st, a Supplementary Estimate for £220,000, for salaries and expenses of the Ministry of Health, and grants in aid in respect of benefits and expenses of administration under the National Health Insurance Acts, was considered.

Sir Kingsley Wood (Parliamentary Secretary to the Ministry of Health) said that in England and Wales, as in Scotland, it had been found that during the financial year, although there had been for the most part no prevalence of any marked epidemic or exceptional outbreak of illness, there had been a wholly exceptional

increase in claims on certain approved societies, especially in the coal-mining areas. The same conditions had led to an increased expenditure on drugs, necessitating an extra grant of £25,000. The Ministry of Health regarded this as a very serious matter, for it was estimated that, after making an allowance for the increased amounts distributed as additional benefits, the claims experience of the approved societies had exceeded that of 1925 by no less than £2,309,000. It was very significant that the rate of increase and the expansion of sickness benefit had not been uniform throughout the country, but that its geographical distribution had corresponded very closely with the incidence of unemployment due to the coal dispute. Up to the beginning of May the sickness experience of the country, apart from a slight tendency to rise, which had been general during the last two or three years, was fairly normal. After that date there was a tremendous rise in the expenditure of the approved societies.

Dr. Shiels asked if there had not been a considerable amount of destitution in the mining areas, and whether many miners had insufficient food. Did not that, apart altogether from the ordinary epidemic curves, prove that there was a great likelihood of excessive sickness in the mining areas?

Sir K. Wood said the answer to that was that, after the termination of the dispute, the average weekly expenditure of certain of the societies specially affected dropped as much as one-third. In some of the societies, in December last, the average weekly expenditure was less than that of December, 1925. While he agreed that in times of industrial depression some measure of increased sickness might be looked for, the Minister of Health (and, he thought, everyone concerned in the matter) could not escape the conclusion that large numbers of insured persons had succeeded in obtaining medical certificates, although they were not, in fact, incapable of work within the definition of the National Insurance Act. This had been confirmed by the very large number of cases that were referred to the medical referees for examination. In the present vote there was an extra sum of £30,000, which was spent in the increased employment of medical referees, because directly the Ministry saw this abnormal rise in the sickness expenditure it got into communication with the medical men of the country and the approved societies, who had very largely increased the employment on the regional medical staffs. The normal number of people who were referred to the medical referees under the Act each year was some 200,000. From the beginning to the end of the coal stoppage the societies, largely on their own account, referred between 400,000 and 500,000 persons to the medical referees. It was a very astonishing thing that some 40 per cent. of the people so referred signed off in preference to presenting themselves for medical examination As for the remainder, the examination proved that instead of the usual experience, which was that of the number who actually presented themselves to the medical referees, some 80 per cent. were found incapable of work, although there were two or three times the number referred, it was found that only some 66 per cent. were incapable of work. Therefore, out of every 100 cases referred to the referees, 40 per cent. signed off and only 60 per cent. presented themselves. Of these 60 per cent., it was found that another 20 per cent. were not incapable of work. Undoubtedly it had been a very abnormal period, and the resumption of work had had a very marked effect on the expenditure so far as medical benefit was concerned: So far as ordinary foresight could go, this was an unforeseen and unfortunate experience as far as national insurance was concerned, which everyone hoped would not be repeated. Things were now rapidly approaching the normal rate of sickness experience, which, he hoped, would soon be reached.

The vote, he added, contained an item in connexion with a new dental service which was being inaugurated in connexion with national insurance. The money was required for the salaries of regional dental officers for the last two months of the present financial year. At present, 6,300 societies were engaged in administering this extra benefit, which was one of the most popular additional benefits under the Act. The scope of the new service had been agreed on by a committee representing the approved societies and the dental profession, almost with unanimity he thought. There was some objection by a very small body as to the terms and conditions of the service. He believed that this new advance, so far as dental treatment was concerned, would have very far-reaching consequences in improving the health of the people.

Mr. Wheatley moved a reduction in the vote by £100 as a protest against the attack which had been made on the medical profession. He said that Sir K. Wood's statement with regard to an honoured and honourable profession could not go unchallenged or uncriticized. It amounted to this: that during the coal stoppage large numbers of the medical profession were guilty of fraud, and that they were aided and abetted in carrying out this fraudulent policy by large masses of the working classes. There was no use mincing matters. If it were true, as Sir K. Wood had alleged, that the approved societies had been deprived of large sums through members of the medical profession granting certificates that were not warranted, then those medical practitioners were guilty of a very gross system of fraud. That was not the view of the medical profession which he had learned from his experience in life or during his brief experience as Minister of Health. He had always been taught to look up to the medical profession as being among the most honourable sections of the community, and he was sure that they would read with amazement the statements just made on behalf of the Government. He had no doubt that the medical profession would find means of clearing its character of the unjust imputation cast on it by the Ministry of Health. The only evidence in support of this amazing charge was the results of the appeals made to the medical referees.

Miss Wilkinson contended that to say that doctors had put people on the fund improperly was not only a libel on the medical profession but an insult to the intelligence of the committee. The doctors had behaved like decent citizens, and as men with some humanity. They had tried to get food for these unfortunate people, whom the Ministry tried to starve.

Dr. Vernon Davies said it was rather an unusual but pleasant experience to hear the medical profession belauded by the Labour party, but Miss Wilkinson had paid them rather a back-handed compliment, because she said that the medical men had been more kind and charitable than the department, and had put these men on to medical benefit when they ought not to have been put there; that they were, in fact, doing a dishonest act, that they were men of dishonour. Malnutrition was not a disease for which medical benefit could be given. If a doctor put on a medical certificate that a person was suffering from disability or malnutrition the approved society could not accept that certificate. The question raised by Sir K. Wood had brought to the front one of the inherent defects of the National Insurance Act which it had been recognized from the beginning was bound to come up some time. His statement as to the great increase in medical benefit, which coincided with the coal stoppage, showed, or rather was an implication, that an extra number of men went on medical benefit, either because they were not genuinely sick or because doctors were lenient in giving them certificates. That was a most serious implication against his profession, and one which ought to be most carefully examined. Doctors were human beings; they had their hopes, desires, and anxieties, and, while in practice, were anxious not to offend their patients unnecessarily. One very strange occurrence, however, was that as soon as the coal stoppage was over there was a sudden drop in benefits. If Miss Wilkinson was right that a great amount of the sickness was due to starvation or malnutrition, it would not have been expected that as soon as the stoppage was over these people would suddenly recover their health and strength and go back to work. Another point that was suspicious was that the approved societies sent a larger number of cases to the medical referees—100 per cent. more than the average. That gave rise to a suspicion that the approved societies thought that some of these people were not genuinely ill, and ought not to have a certificate. Another suspicious sign was that 40 per cent. of those who ought to have gone to the medical referees suddenly decided to sign off. At the present time the doctor had to please his panel patients if he wanted to keep his panel practice; that was the particular difficulty. If a doctor wanted to be absolutely honest to his own conscience he had to run the risk of offending patients and of losing his practice. In all cases there was a certain element of doubt. It was very difficult for a doctor to prove whether a man was fit for work. So, although he thought that the doctors, perhaps, were under a little suspicion, and perhaps were a little too lenient and did not exercise sufficient care, the main result that the committee would judge from the estimate now brought forward was this: that a certain number of people, finding that they were locked out and that they could not get relief from the Poor Law, suddenly remembered that there was such a thing as a panel doctor, and if they had a cough or a cold that they could legitimately get medical benefit. Having got on the list, they took good care that they did not get off until they were absolutely fit and strong. That, perhaps, was human nature. So long as national insurance was on its present basis that difficulty would have to be faced—the man who was anxious to get benefit and the doctor who was in the awkward position of having to decide whether the patient was ill or well. The result was that the moral of the patient, and the moral of the doctor in some cases, was sapped, so that the medical benefit suddenly increased with the coal stoppage and suddenly decreased when the stoppage was over.

Replying to the debate, Sir K. Wood said it was only right to say that the medical profession itself took action in this matter. In July the Minister of Health communicated with the appropriate authority, and in October the National Insurance Controller attended a representative Conference, and put the whole facts before the medical men chiefly affected. A very significant resolution was passed by the Conference, asking the Insurance Acts Committee to consider what practical steps could be taken to meet the difficulty, and pledging themselves to use their influence locally in endeavouring to secure strict adherence to the principles governing certification for the purpose of the National Health Insurance Act. Therefore, he (Sir K. Wood) hoped no one would think he had overstated the case, or that the

medical men themselves were not alive to the evils which had resulted from the state of affairs he had indicated. With regard to the dental service, the department had appointed some seven or eight new dental regional officers. The chief dental officer would receive a salary of £1,000, and the others £700 or £800 a year. These sums were moderate and quite adequate, having regard to the duties.

The amendment was rejected by 187 votes to 78—majority 109; and the vote was agreed to by 189 votes to 75—majority 114.

National Health Insurance.

Mr. Chamberlain cannot yet make any statement as to when a bill will be introduced giving effect to the recommendations of the Royal Commission on National Health Insurance. He hopes to include in that bill a provision that the fee for the medical examination of emigrants seeking assisted passages shall be paid from National Health Insurance funds.

Mr. Chamberlain rules that there is no conflict with any provisions of the National Health Insurance Acts in the order of the West Ham Board of Guardians that any member of their resident staff who is sick must make a claim for sickness benefit from his approved society, the benefit so receivable being deducted from his salary.

Mr. Couper asked whether action was proposed on representations made by the Pharmaceutical Society against the practice of doctors in England and Wales dispensing medicines and supplying surgical requisites. Mr. Chamberlain replied that legislation would be needed to preclude medical practitioners from doing this, and he was not, as at present advised, prepared to introduce it.

The Minister of Health cannot extend the period during which persons could become voluntary contributors under the combined health and pensions insurance scheme. The period ended on January 2nd.

Insulin in Diabetes.—Brigadier-General Brooke asked the Minister of Health whether his medical officers still recommended the use of insulin for the treatment of diabetes; and whether, in view of the attacks now made on this remedy, he would define the position of his department. Mr. Chamberlain said it was not ordinarily part of the duties of medical officers of the Ministry to make recommendations in regard to treatment, though regional medical officers might occasionally offer suggestions at the request of an insurance practitioner. The administration of insulin was unquestionably of great value in suitable cases. The mortality rate from diabetes did not appear to be increasing, although the number of deaths from this disease naturally tended to increase with the increase in the population.

Committee on Mental Deficiency.—On February 21st the Duchess of Atholl told Mr. Cove that the committee which was inquiring into certain questions relating to mental deficiency among adults as well as among children consisted of the following members: Mr. Arthur H. Wood (chairman), Dr. R. H. Crowley (vice-chairman), Mr. C. Eaton, Mrs. Pinsent, Miss Evelyn Fox, Miss Redfern, Professor Cyril Burt, Dr. F. C. Shrubsall, Dr. A. F. Tredgold, Dr. F. Douglas Turner, with Dr. N. D. Bosworth Smith as secretary. The President of the Board of Education understood that evidence had not yet been invited. She could not say whether the committee's report would be published.

Miner's Nystagmus and Alcohol.—Asked whether, in a compensation case in Yorkshire, a statement had been made that nystagmus was improved by excessive drinking, the Home Secretary said the Miner's Nystagmus Committee of the Medical Research Council had found that, while large doses of alcohol might lessen for an hour or so the oscillation of the eyes, the influence of alcohol, generally speaking, was markedly harmful and delayed recovery.

Poor Law Emergency Provisions (Scotland) Bill.—On February 22nd the Lord Advocate (Mr. Watson) moved the second reading of the Poor Law Emergency Provisions (Scotland) Bill. This measure legalizes the payment of poor relief to dependants of persons involved in trade disputes in Scotland and brings the law into harmony with that in England. It arose out of the payment of such relief by the parish councils during the coal stoppage of last year. These payments were declared by the Court of Session to be illegal. In the course of the debate Dr. Shiels remarked that it was a very pleasant thing to know that it was now recognized that in an industrial dispute the women and children would not be factors in the dispute. An amendment moved by the Labour party, urging that the cost should be made a national charge and declining to agree to the limitation of the Exchequer contribution to a maximum of 40 per cent. of the expenditure, as provided in the bill, was rejected by 257 votes to 127—majority 130—and the bill was then read a second time.

Tuberculosis in the Services.—Colonel Headlam (Secretary of the Admiralty) announced that 197 men were discharged from the Royal Navy with tuberculosis in 1926. In six cases this was found to be attributable to conditions of service, and pensions were awarded. Answering Dr. V. Davies, on February 21st, Mr. Bridgeman said the six men discharged from the navy during 1926 for tuberculosis held to be attributable to conditions of service had served 4, 9, 9, 14, 15, and 20 years. Sir L. [illegible] Dr. Davies that similar details were not [illegible] army.

Economics in Pensions Administration.—In Committee on the Civil Service Supplementary Estimates, in the House of Commons, on February 21st, Major Tryon (*Minister of Pensions*) said there had been a great reduction of complaints regarding administration, and a smaller staff was sufficient. Thanks to the committee which had considered the question of artificial limbs, it had been possible to effect a considerable saving on that charge. The limbs supplied were very satisfactory. Mr. F. Roberts, a former Minister of Pensions, pointed out that there was an estimated saving of £5,000 on salaries, wages, and allowances in respect of medical services. He asked if that was due to a demand made to the men under treatment to go to their panel doctors. Major Tryon replied that the saving did not indicate any change in the medical policy of the Ministry, but was due entirely to the falling off in the volume of work. The vote, which was for £420,600, was carried.

Insanitary Conditions on Emigrant Ships.—On a Supplementary Estimate of £142,000 for overseas settlement, Mr. W. Baker drew attention to allegations about overcrowding and insanitary conditions on ships carrying British emigrants to Canada. Mr. Ormsby-Gore said the Board of Trade and those who supervised the work of migration did their utmost to prevent such conditions arising, but when rough seas prevailed sea travelling in a crowded ship was generally beastly.

Certified Special Schools for Children.—The Duchess of Atholl stated, on February 21st, that there were 75 certified special schools for the blind on March 31st, 1926, 49 for the deaf, 192 for the mentally defective, 233 for the physically defective, and 6 for the epileptic. The estimated number of children on the registers on March 31st, 1926, were: blind, 3,919; deaf, 4,230; mentally defective, 16,331; physically defective, 18,804; epileptic, 520.

Notes in Brief.

In the past eighteen months accommodation in open-air schools in England and Wales has been increased by 900 places, and proposals have been approved for over 1,500 further places.

Mr. Chamberlain does not propose to take further action on the recent decision in the King's Bench Division that a guardian of the poor receiving and paying in full for treatment in the union hospital is not disqualified.

The committee appointed to deal with the preparation and testing of vaccine lymph and with cognate questions has not reported.

It has not yet been possible to arrange a test case on the liability of offices to inspection under the Factories Acts.

No milk is imported into England from Ireland, the Channel Islands, or the Isle of Man.

It is hoped that the Committee on Youthful Offenders will report within two months. The Home Secretary will then consider whether legislation is required on the report of the Committee on Offences against Young Persons.

No plans have been submitted for the additional accommodation required for the headquarters of London University at South Kensington.

The Minister of Agriculture sees no reason for departing from the decision reached by a Select Committee of the House of Lords in 1919 to the effect that the use of an anaesthetic in the castration of animals, except dogs and cats over six months of age, is neither desirable nor practicable.

Tests and inquiries about the effect of "ultra-violet glass" on the health of school children have not reached a stage where any general recommendation can be made.

The Colonial Secretary is awaiting a report from the High Commissioner for Palestine on quarantine arrangements at Haifa. A question in the House of Commons suggested that the quarantine station was near a mosquito-breeding swamp.

On February 21st the Sale of Food and Drugs Bill was read a second time and committed to a Standing Committee.

There were 379 men and 1,057 boys accepted for the Air Force in 1926, while 258 men and 234 boys were rejected on account of some physical or medical disability.

The Minister of Transport is considering whether the bill for the regulation of traffic on roads should deal with smoke issued by steam vehicles.

The total of persons insured under the National Insurance Acts in England and Wales during 1926 was roughly the same as in 1925—14,196,000.

The Services.

DEATHS IN THE SERVICES.

FLEET SURGEON JOHN BELLHOUSE BOWDEN TRIGGS, R.N.(ret.), died in a nursing home at Malden, Surrey, on February 1st, aged 75. He was educated at University College, London, and at Aberdeen, where he graduated M.B. and C.M. in 1873; he took the L.S.A. in 1872, and the M.R.C.S. in 1874, and entered the navy soon after; he was medical officer of H.M.S. *Active* during the Zulu war of 1879, receiving the medal. In 1892 he received a medal and diploma from the Venezuelan Red Cross Society for his services to the wounded in the neighbourhood of La Guayra, during the revolution in Venezuela in that year.

Lieut.-Colonel Henry Pruce Jervis, Bombay Medical Service (ret.), died at New Milton, Hants, on February 7th, aged 71. He was the son of Thomas Jervis, superintendent of Customs, Bombay, and was educated at the Grant Medical College, Bombay, where he gained the Reid scholarship in anatomy and physiology, and the Anderson scholarship in surgery. Subsequently he was a student of St. Bartholomew's Hospital Medical College, and took the L.S.A. and the L.R.C.S.Ed. in 1877. He entered the I.M.S. as surgeon on October 1st, 1877, became lieutenant-colonel after twenty years' service, and retired on November 27th, 1902. He served in the third Burmese war in 1885-87, receiving the frontier medal with a clasp.

Medical News.

THE Ministry of Health is about to appoint a Departmental Committee to consider a draft bill prepared by the Joint Committee of Qualified Opticians, which seeks to provide for the registration of optical practitioners and to regulate the practice of sight-testing.

THE 154th anniversary dinner of the Medical Society of London will be held at the Grand Hotel, Trafalgar Square, on Monday, March 7th, at 7.30 p.m. Sir Humphry Rolleston, Bt., president, will be in the chair.

AT a general meeting of the Royal Society of Medicine to be held at 1, Wimpole Street, on Thursday, April 7th, at 5 p.m., a discussion will be held on blood-letting. Fellows wishing to take part are asked to send in their names to the secretary of the society.

PROFESSOR S. LYLE CUMMINS, C.B., C.M.G., M.D., professor of tuberculosis, University College, Cardiff, will read a paper at a meeting of the North-Western Tuberculosis Society to be held at 3.15 on March 31st, 1927, at the Public Health Laboratory, York Place, Oxford Road, Manchester. The subject selected is "The bearing of recent laboratory research on clinical conceptions in tuberculosis." Members of the Lancashire and Cheshire Branch are cordially invited to attend.

AN illustrated descriptive account in English of the Bad-Nauheim cure has been compiled by the association of medical practitioners of this spa, and may be obtained from Dr. Ricklinger. Details are given of the methods and treatment, the effects of the carbonic acid baths on different ailments, and the indications for this kind of spa therapy.

AT a meeting of the London Natural History Society on Tuesday, March 1st, at 6.30 p.m., in Hall 40, Winchester House, E.C., a lecture on tsetse flies and their significance to tropical Africa will be given by Major E. E. Austen, D.S.O., Deputy Keeper, Department of Entomology, British Museum. Visitors are welcomed.

THE Post-Graduate Hostel will hold a ladies' night at the Imperial Hotel, Russell Square, W.C.1, on Monday, February 28th, when Mr. E. Muirhead Little, F.R.C.S., will lecture on the history of Bloomsbury; all medical practitioners, ladies, and friends are welcome. The lecture will commence at 9 p.m. Dinner (5s.) will be served at 8 p.m., and coffee and biscuits (6d.) can be obtained at 10 p.m.

DR. ARTHUR WHITFIELD will lecture for the Fellowship of Medicine on the differential diagnosis of some acute rashes, at the Medical Society, 11, Chandos Street, W., at 5 p.m., on March 3rd, and on March 1st, at 3.15 p.m., Dr. R. Wade will lecture on safety in anaesthesia, at the Royal Northern Hospital. These lectures are free to medical practitioners. The Brompton Hospital will hold an all-day course from March 7th to 12th, including demonstrations in the cardiographic and *x*-ray departments and the wards. From March 14th to 25th a course in gynaecology will be given at the Chelsea Hospital. From March 21st to April 2nd a comprehensive course in orthopaedics will be held at the Royal National Orthopaedic Hospital, and a course primarily intended for general practitioners in the late afternoons at the London Temperance Hospital. From March 28th to April 9th there will be an all-day course in diseases of children at the Queen's Hospital. At the Royal Eye Hospital a series of demonstrations will be given on diagnosis and treatment from March 28th for two weeks. The Fellowship arranges for practical courses in obstetrics and anaesthetics and for clinical assistantships in gynaecology. Copies of all syllabuses and of the *Post-Graduate Medical Journal* may be obtained from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

A SHORT post-graduate course in orthopaedics will be given by Mr. Godfrey Taunton at St. Bartholomew's Hospital, Rochester, on March 1st and following Tuesdays at 3 p.m. Lectures on other subjects are being arranged. Practitioners wishing to attend are asked to notify Dr. Myles Tonks, Manor House, Brompton, Chatham.

MAJOR-GENERAL T. H. SYMONS, Director-General Indian Medical Service, has been elected president of the next congress of the Far Eastern Association of Tropical Medicine, which will be held at Calcutta from December 5th to 22nd.

THE annual dinner of the Cambridge Graduates' Medical Club will be held, as already announced, at the Langham Hotel on Tuesday, March 1st, at 7.30 p.m., with Sir Humphry Rolleston, president, in the chair. All Cambridge medical men who are graduates of the University are eligible for membership. Application forms can be obtained from the honorary secretaries, Mr. R. N. Vick of 113, Harley Street, W., and Dr. F. G. Chandler of 1, Park Square West, Portland Place, N.W.1.

PUBLIC health officials of twelve foreign countries are at present paying a six weeks' visit to England under the auspices of the Health Organization of the League of Nations. Having spent this past week in London the party is dividing into groups to visit Liverpool, Glasgow, large industrial and residential centres, and rural areas. The final week will be spent in London, and the party will probably leave England on April 2nd for Geneva, where a brief study will be made of the working of the Health Organization of the League. This is the fifth party to make a visit of this kind.

THE Wellcome Historical Medical Museum, 54A, Wigmore Street, will be closed from Monday, February 28th, until March 14th.

RECENT bequests to hospitals include £5,000 to the Oldham Infirmary for the endowment of two beds under the will of Mr. James Whitehead. Mr. E. S. Moore of Erdington has bequeathed £1,250 each to the Birmingham General Hospital; Jaffray Hospital, Birmingham; Queen's Hospital, Birmingham; Birmingham and Midland Skin and Urinary Hospital; Birmingham and Midland Hospital for Women; Birmingham Maternity Hospital; Birmingham and Midland Eye Hospital; and the Birmingham and Midland Ear and Throat Hospital; and £1,000 each to the Children's Hospital, Birmingham; Royal Orthopaedic and Spinal Hospital, Birmingham; Taylor Memorial Hospital of Rest, Sparkhill; and the Smedley Memorial Hospital, Matlock. Miss S. E. F. Payne bequeathed £500 to the Hospital for Sick Children, Great Ormond Street, £1,000 to the Children's Hospital, Carlton, Melbourne, and £250 to the Women's Convalescent Home, Clayton, Melbourne. Miss S. M. Harrop of Colwyn Bay bequeathed £2,000 to the Ancoats Hospital and Dispensary, £500 to the Manchester Royal Infirmary, and £250 to the Colwyn Bay Hospital.

UNDER the name of Journées Médicales Marseillaises et Coloniales a congress will be held at Marseilles from April 20th to 24th, when the following papers, among others, will be read: The role of the streptococcus in the etiology of scarlet fever, by Professor Cantacuzène of Bucarest; recent advances in the treatment of cancer, by Dr. Mayer of Brussels; malaria, by Professor Ottolenghi of Bologna; beriberi, by Dr. Noel Bernard of Indo-China; bone-grafting, by Professor Imbert of Marseilles. Further information can be obtained from the general secretary, Dr. André Sauvan, 40, Allées Léon-Gambetta, Marseilles.

THE French Goverment has presented Dr. Vincenzo Neri, professor of nervous diseases at the University of Bologna, with the Cross of the Legion of Honour.

PROFESSOR MOURE, who formerly occupied the chair of oto-rhino-laryngology at Bordeaux University, was recently presented with a medallion of himself by his former pupils and friends.

ALTHOUGH the measures adopted in Germany in recent years to instruct the population in hygienic principles have proved fruitful, the movement has, for various reasons, failed to reach the industrial middle classes, and an effort is now being made to meet this defect. Several insurance companies of good standing have agreed to adopt the plan, successfully applied in America, of offering periodical medical examinations to their clients, the medical fee to be defrayed by the companies and the doctor to give such advice as may appear necessary. A central life assurance hygienic office, with a strong staff, has already been established in Berlin, and will control this part of the companies' business.

THE thirty-ninth Congress of the German Society for Internal Medicine will be held at Wiesbaden, under the presidency of Professor Naegeli of Zürich, from April 25th to 28th, when the following subjects will be discussed: (1) Psychotherapy, introduced by Gaupp of Talingen and Fleischmann of Nassau; (2) the results of the recent functional investigations of the stomach and duodenum, introduced by G. Katsch of Frankfort. A joint meeting with the German Röntgen Society will be held on April 28th, when a discussion will take place on the significance of Röntgen-ray examination of the lungs and mediastinum for internal medicine (excluding tuberculosis), introduced by Dietlen of Homburg Saar, Assmann of Leipzig, Haenisch and Lorey of Hamburg, and Fleischner of Vienna.

THE fifth edition of the Dutch *Pharmacopoeia* will be published on April 1st.

ACCORDING to official statistics there are 8,000 medical practitioners and 2,000 dentists in Poland; 25 per cent. of the doctors are in practice at Warsaw.

THE following appointments have recently been made in foreign faculties of medicine: Dr. Savy, professor of therapeutics, hydrology, and climatology at Lyons; Dr. Leclercq, professor of medical jurisprudence at Lille; and Dr. Luigi Pirus, professor of hygiene, medical jurisprudence, and bacteriology at Parma.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to ***The EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1.***

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the BRITISH MEDICAL JOURNAL alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the BRITISH MEDICAL JOURNAL must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the JOURNAL, should be addressed to the Financial Secretary and Business Manager.

The ***TELEPHONE NUMBERS*** of the British Medical Association and the BRITISH MEDICAL JOURNAL are *MUSEUM 9861, 9862, 9863,* and *9864* (internal exchange, four lines).

The ***TELEGRAPHIC ADDRESSES*** are:

EDITOR of the BRITISH MEDICAL JOURNAL, *Aitiology Westcent, London.*

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.), *Articulate Westcent, London.*

MEDICAL SECRETARY, *Medisecra Westcent, London.*

The address of the Irish Office of the British Medical Association is 16, South Frederick Street, Dublin (telegrams: *Bacillus, Dublin*; telephone: 4737 Dublin), and of the Scottish Office, 6, Drumsheugh Gardens, Edinburgh (telegrams: *Associate, Edinburgh*; telephone: 4361 Central).

QUERIES AND ANSWERS.

MORBID SHYNESS IN A CHILD.

"K. H. G." asks for suggestions for the treatment of excessive shyness in a girl, aged 7, who is stated to have suffered from "fits" at the age of 12 months, since when there have been none. Her physical condition is good, and she is quite happy and bright when among the other members of her family, but as soon as a stranger enters her home she runs to her mother and hides her face. She refuses to meet even a playmate of her own age. Chastisement (as might be expected) has not improved her.

CHRONIC OTORRHOEA.

DR. G. H. RUTTER (Eastbourne) writes in reply to "B. B.": It would *not be very probable* (but impossible to say without inspection or fuller details as to the exact condition) that any damage would be done by ionization in a case of chronic otorrhoea. Cases of several months' standing in about 90 cent. of those treated do remarkably well, and show no discharge after a solitary treatment of a few minutes. It is unnecessary to say that only a properly qualified medical man with experience should attempt such a case.

DR. W. E. CROSBIE (Alder Hey Hospital, West Derby, Liverpool) writes: *If* "B. B.'s" case is one of chronic tympanic sepsis uncomplicated by bone disease, ionization should alleviate the condition and will in all probability effect a
of course, that there are no extraneous
Ionization of an ear is not likely to do any

LETTERS, NOTES, ETC.

A COMMUNICATION on the subject of assistants to general practitioners has been received from a correspondent in Birmingham, who has, however, omitted to enclose his name and address.

EPIPHORA.

DR. A. T. BRAND (Driffield) writes: Has Dr. A. C. Balfour (JOURNAL, February 19th, p. 361) stated the correct strength, or rather "weakness," of the adrenaline chloride lotion for cases of epiphora? One drop in 16.6 ounces of water is suggestive of homoeopathic *dilution*. I have used the full strength in conjunctivitis with immediate removal (if temporary) of the congestion, with no discomfort.

HAEMATOLOGY.

DR. A. PINEY (Charing Cross Hospital Institute of Pathology) writes: I read with great interest Dr. Eve's article on "Paraplegia (megalocytic) cured by hydrochloric acid" (JOURNAL, February 19th, p. 323). The case is admittedly a striking one, in which the diagnosis appears to have been made on the basis of the curve graphically plotted from measurements of the size of red corpuscles. Dr. Eve states: "Haematology and all its complexities gave no light." It would be interesting to know why he regards the process of measuring the size of red corpuscles as belonging to some branch of science other than haematology. The not infrequent attacks on the value of haematological data suggest that Dr. Eve is not the only one who is unaware of the extent of the ramifications of the subject.

A MEMORABLE OBSTETRIC TRAGEDY.

"M. E. R." writes: It may interest readers of the recent article on the royal tragedy of Princess Charlotte's accouchement (BRITISH MEDICAL JOURNAL, Feb. 5th, p. 255) to learn that a number of mourning tokens dealing with the event were struck and that some of them still exist. A specimen handled lately was extracted, along with a quantity of foreign coins and metal discs, from an automatic machine by its exasperated owner. It has the appearance of a copper coin about the size of a halfpenny. The obverse shows the bust of a grim and elderly-looking lady with filleted hair, with around it the inscription, "H.R.H. The Princess Charlotte." The reverse, within an inscription to the effect that "Britannia mourns her Princess dead," shows an urn on a pedestal, the whole overshadowed by a tree-like growth, which may be either a cypress or a weeping willow; underneath this lugubrious device are the words, "*Died November 6th, 1817. Aged 21.*"

CHOREA IN INDIA.

DR. E. F. SKINNER (*Sheffield*) writes: I have this week dispatched to various medical missionaries in India a number of letters in the form of a printed circular, asking for information on the subject of chorea in natives, and by a clerical error I find that a few have been sent out without the name of the addressee having been inserted. I would like to offer my apologies to those medical men and women who may receive one of these letters.

OPIUM SMOKE AS AN ANAESTHETIC.

DR. G. L. *DESHMUKH (Bombay)* writes: The accident recorded below happened in Koshi-Shang, the outport of Bangkok, on a British ship of which I was medical officer. We were loading a cargo of rice for London when one of the slings gave way and the rope rent open the scrotum of a Siamese labourer. Being unable to give chloroform and attend to the injuries alone, and considering it cruel to handle the torn part without anaesthesia, I asked his friends to give him his opium hookah—an L-shaped tube on which an opium ball is fixed, ignited and smoked (it is the practice in these parts to drown the fatigue of the day in opium smoke). After a few whiffs he permitted me to wash the part and replace the structures; a few more puffs and I was able to suture the rent. He was by this time fast asleep, and we removed him to hospital on board the vessel. On awaking he began to feel the part and inquired what had happened. We remained in the neighbourhood for seven days, and then sent the patient to a hospital at some distance. The report received from the hospital stated that there was no sepsis and that he was improving. I leave it to the medical world and to scientists to decide whether opium smoke is to take a place in the field of anaesthetics.

PRECONCEIVED PERFECTION.

THE object of the Quest Society is "to seek for spiritual values in religion, philosophy, science, literature, and art." To the quarterly review Professor D. Fraser on science and preconceived *perfec-*s, Professor Harris contends, are to embody some religious opinion r Hoffmann of Nüremburg *objected* to Harvey's idea of the circulation of the blood, because it "and error in making the blood return rt to be reconcocted, thus spoiling the rely to find t

Steusen was criticized for saying that as it was held that the soul was in the heart, that the heart could be a common muscle. Tagliaccozzi was denounced for his operation of rhinoplasty, because he had dared impiously to alter a countenance "made in the image of God." The Rev. Dr. Rowley accused Edward Jenner of presumption and violation of religion in producing cow-pox to interfere with small-pox—a visitation ordained by God. He forgot, apparently, that cow-pox must have been a visitation from *God on cattle.* Gall was objected to, not because he taught an absurd system of cerebral physiology, but because he had outraged religion by teaching that *mental and moral qualities had a physical basis* in the brain. The most recent preconception alluded to by Professor Harris is the objection formerly raised against chloroform, *in that to abolish pain,* even of childbirth, was "contrary to Nature." The Quest Society might carry the matter a little further and inquire how far some modern ideas about man and his destiny are tinged with the notion of preconceived perfection.

A WARNING.

DR. N. F. WINDER (209, *Roundhay Road, Leeds*) writes: I am informed that a man, who is described as being about 5 ft. 1 in. in height, with fair brown hair, and wearing a dark blue water- my name among London practitioners ial assistance, stating that he is tuber- impersonation, and London practitioners should be on their guard.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals, will be found at pages 41, 44, 45, 48, and 47 of our advertisement columns, and advertisements as to partnerships, assistantships, and locumtenencies at pages 42 and 43.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 75.

A British Medical Association Lecture
ON
GASTRIC HAEMORRHAGE.

GIVEN BEFORE THE EXETER DIVISION
BY
CHARLES MILLER, C.B.E., M.D., F.R.C.P.,
CONSULTING PHYSICIAN TO THE LONDON HOSPITAL; ASSISTANT PHYSICIAN, ROYAL DEVON AND EXETER HOSPITAL.

FEW occurrences cause so much consternation as the vomiting of a large quantity of blood. The equally serious but less sensational events, fainting, sudden pallor, and the subsequent passage of a tarry stool, do not produce the same effect on the minds of the patient and his friends. But from the standpoint of the doctor the two events are seen to be of equal importance, for they point to internal haemorrhage in stomach or duodenum. For convenience I propose to consider the acid part of the duodenum as part of the stomach, as both are subject to the same kind of digestive juice. Pathologically the two regions are subject to similar disorders, though anatomically they have to be described separately.

It used to be thought that melaena without haematemesis was a point in favour of the diagnosis of duodenal ulcer rather than of gastric ulcer. But this condition is found in cases of gastric ulcer, and, on the other hand, haematemesis can occur with duodenal ulcer. In dealing briefly with gastric haemorrhage only copious haemorrhage will be considered. Occult blood in the stools has its value in the diagnosis of certain alimentary disorders, but is outside the subject of this occasion.

At the beginning of the century haematemesis, except in cases of cirrhosis of the liver, was thought to be a sure sign of gastric ulcer. By gastric ulcer was meant a large ulcerated area, visible and palpable in the exposed stomach. The advance in gastric surgery has proved many ideas about disorders of the stomach to be wrong, and gastric haemorrhage has been shown to be due to many conditions other than a gross ulcer of the stomach. It may be said that, although a gastric ulcer can be associated with copious haemorrhage, many large chronic ulcers persist for years without any noticeable bleeding, and many cases of copious haemorrhage are found among patients who have no sign of ulcer of any size.

CAUSES OF GASTRIC HAEMORRHAGE.

As a general principle it may be stated that when haemorrhage occurs there must have been loss of tissue —that is, ulceration. The ulceration may be minute and even microscopic. Gastric ulceration is due to the digestion of the stomach wall by the gastric juice. But before self-digestion takes place there is some damage to the stomach wall, for gastric juice does not digest healthy mucous membrane.

Gastric ulceration is due to the digestion of damaged tissue in the wall of the stomach. The wall of the stomach is well supplied with blood, and during digestion it has the appearance of soft red velvet, which looks as if it would bleed freely if scratched. The blood should, and does, remain in the blood vessels; but if there is any damaged tissue the gastric juice will digest it, and may open a blood vessel or vessels. Of course, trauma may directly produce haemorrhage. The act of violent vomiting, the passage of a tube into the stomach, a blow on the epigastrium, may produce haemorrhage from a stomach that is not ulcerated even minutely, and the damage done by severe trauma can produce subsequent ulceration. But haemorrhage from the stomach is usually a sequel to the digestion of the mucous membrane and deeper parts of the stomach wall by the action of the gastric juice.

It becomes necessary to examine the various processes by which the stomach can be damaged. Trauma has already been mentioned. It is conceivable—in fact it has happened —that trauma producing submucous haemorrhage has been followed by chronic ulceration.

Corrosive poisons, of course, will damage the stomach and produce haemorrhage by their own action; I can remember a case of repeated haemorrhage coming from a chronic gastric ulcer following attempted suicide by spirits of salt some years before. But such cases as these are few and not worth further consideration at the moment.

Apart from such traumatic causes, other possible causes of damage to the stomach have to be considered. First, interruption of the blood supply will undoubtedly lead to the death of tissue locally, and the gastric juice will do the rest.

In cases of mitral stenosis when, as a terminal event, auricular emboli are showered into the arterial stream some may block up vessels in the wall of the stomach. The neighbouring mucous membrane is starved of blood and in its damaged state can be digested. The digestion may go further than the block in the arteriole and haemorrhage can follow. This is a terminal event, and sometimes the stomach is found *post mortem* to be filled with blood. An example of this cause of gastric haemorrhage was afforded by the case of a man, aged 26, who died from mitral stenosis. *Post mortem* there were recent infarcts in the spleen and kidneys; the stomach was full of blood; there were numerous small ulcers throughout all parts of the stomach. Microscopic examination showed blocking of some arterioles and a thrombus in a branch of the coronary artery. In one section the artery was empty and its wall deficient at one point so that the lumen communicated with the cavity of the stomach.

In cases of progressive endocarditis gastric haemorrhage is sometimes seen. In these cases also emboli are the cause, but here the emboli may contain microbes and can produce the effects of acute local inflammation. A woman, aged 51, died from ulcerative endocarditis of the aortic and mitral valves. *Post mortem* in the stomach there were many small punched-out ulcers situated in greatest numbers in the fundus. There was some blood in the stomach. Arterial emboli can be spread throughout the stomach, but are usually most numerous in the fundus, which is not often the site of gastric ulcer.

Obstruction of veins can also be followed by similar results. In the case of a boy aged 12, who died of haematemesis, there was such proliferation of the intima of the veins that many sections showed complete blocking. Here there were numerous haemorrhagic points visible in the stomach.

In general miliary tuberculosis, when the blood is soaking the tissues with tubercle bacilli, tubercles may spring up in the gastric wall and are promptly digested. Occasionally, but rarely, slight haemorrhage may occur from the bases of the digested tubercles.

Cirrhosis of the liver and other conditions which produce portal congestion can cause haemorrhage. The explanation is that the bleeding comes from the bursting of a full vein. But in such cases the circulation in the portal area is slowed, and stagnation results. Conceivably this state of affairs would help the gastric juice to effect some superficial ulceration, leading very easily to haemorrhage. Also it should be remembered that chronic gastric ulceration is not uncommon in cases of alcoholic cirrhosis of the liver.

Gastric haemorrhage is sometimes seen in patients who have a raised blood pressure. In such subjects haemorrhage can occur from any region in which the arteries do not derive much support from the tissues through which they are travelling. Nose-bleeding, cerebral haemorrhage, and gastric haemorrhage may occur. In the early days of gastric surgery when gastro-jejunostomy was the treatment of most gastric conditions, a man of 30 was admitted for haematemesis. Later gastro-jejunostomy was performed. He was readmitted for haematuria. He had a systolic blood pressure of 210 mm. of mercury, retinal haemorrhages, and granular casts in the urine. *Post mortem* small fibrous kidneys were found.

Primary blood diseases frequently produce subcutaneous and other haemorrhage, and the stomach does not escape, but this form of haemorrhage need not be considered further.

The part that syphilis plays in the production of gastric ulceration and haemorrhage can be best illustrated by the recital of two cases. A man aged 35, a schoolmaster, was admitted to hospital pale and collapsed after haematemesis.

After he had recovered the abdomen was opened and several recent gummata were seen in the liver. The remainder of the liver appeared to be healthy. Certainly there was no great amount of fibrosis, and it could not be argued that portal congestion was an important factor. Possibly he had a syphilitic gastric ulcer which escaped notice. Another man was admitted in a similar state whose Wassermann reaction was found to be positive. He was given antisyphilitic treatment and did well. No abnormality was found radiologically. He went out and visited the seaside, where he died, on the pier, from haematemesis. Further there is McNee's classical case in which he found spirochaetes in the wall of a gastric ulcer.

The two cases I have quoted show that haematemesis can occur in the syphilitic, and McNee's case proves that syphilis can cause gastric ulceration. Possibly syphilitic ulceration is more frequent than is thought.

CHRONIC GASTRIC ULCER.

So far, with the exception of cirrhosis, only the less common causes of gastric haemorrhage have been considered.

In chronic gastric ulcer a vessel of some size in the base or wall may be eroded. There is no difficulty here in appreciating how haemorrhage arises. The exposed vessel is eroded by the action of the gastric juice. Such an event occurs commonly in ulcers of the lesser curvature that become adherent to the pancreas. The splenic vein may be in the floor of the ulcer, and haemorrhage from it may be very copious. Of the chronic gastric ulcers this form is the one most commonly associated with severe bleeding.

CANCER OF THE STOMACH.

It is also easy to see how haemorrhage can occur with cancer of the stomach. The growth, as it spreads, contains much semi-necrotic tissue which is readily digested and ulcerated. Bleeding can occur, and usually does, but infrequently in large amount. Blood is often seen in the recovered test meal in cases of gastric carcinoma, and if it is present in all specimens of a fractional test meal the diagnosis of growth receives strong support. Also the repeated discovery of occult blood in the stools is an important diagnostic point in a suspected case. But a haematemesis that blanches the patient is not as common in carcinoma of the stomach as in cases of simple chronic ulceration.

ACUTE ULCER.

These disorders, however, do not provide more than half of the cases admitted to hospital for haematemesis or melaena. We are all familiar with the pale, plump young woman who vomits blood, and is admitted in a collapsed condition. But it will be the experience of most doctors that young women suffer less from gastric haemorrhage than they did fifteen years ago. Perhaps the greater freedom of limb and increased activity, and the more hygienic dress of to-day, have improved the health of young women in this respect as in many others. Chlorosis is now a rare disease. Indigestion and chlorosis went hand in hand. The disappearance of chlorosis is contemporary with the smaller incidence of gastric haemorrhage in young women.

At one time, in the earlier days of gastric surgery, it was thought that these cases were surgical emergencies. The results were not satisfactory. As a rule nothing was found in the stomach except blood, and in many cases the operation was more than the patient could stand. Even at the *post-mortem* examination it was difficult to see where the haemorrhage had occurred. It is obvious that in such cases the bleeding must be from many small points. If we remember that there is a redundance of mucous membrane in the stomach it is easy to imagine how a minute ulcer can be covered over by the neighbouring mucous membrane.

When Matthes was attempting to produce artificial ulcers in the stomachs of dogs, he found great difficulty in doing so. If he removed a small area of mucous membrane the bare area was soon made invisible by the contraction of the smooth muscle and the covering made by the surrounding mucous membrane. He attempted to get over this difficulty by suturing the muscular coat to a glass ring placed on the peritoneal surface. Even so the bare area was no further ulcerated, and the mucous membrane grew over it. This shows that small ulcers are easily obliterated by the contraction of the underlying muscle and the new covering provided by the mucous membrane. Actually he was unable to produce a lasting ulcer until he had given large quantities of acid with the food.

GASTROSTAXIS.

The condition of gastric haemorrhage without any obvious ulceration or bleeding point has been called "gastrostaxis." There is a danger in coining new words to describe morbid conditions, unless the word gives some explanation of the condition. There is no harm in using such a word as "gastrostaxis" if the user is merely describing a phenomenon, and does not think that he has given an explanation of the cause of the phenomenon.

I have attempted to argue that stomachs bleed if they digest their own wall so as to open blood vessels, and that to allow this process to begin some part of the wall of the stomach has previously been damaged and rendered necrotic. If we keep the term ulcer, either gastric or duodenal, for something gross that can be seen and felt, we must have some other term for cases of microscopic or minute ulceration in which haemorrhage occurs. The haemorrhage may be the only clinical evidence of its presence, and *post mortem*, but for the haemorrhage, the stomach might pass as normal to the naked eye. The word "erosions" has been used to denote these minute and even microscopic ulcers. Even if they are just visible these small acute ulcers can be called erosions. It does not matter much to clinicians whether they are just visible or invisible, for it is to be hoped that they will never see during life the inside of a stomach in which there has been haemorrhage from "erosions."

These minute ulcers are best seen where lymphatic tissue is most thickly spread—that is, along the lesser curvature and in the distal part of the stomach. There are also smaller isolated lymphatic follicles scattered throughout the stomach. The lymphatic tissue of the stomach behaves in the same way as lymphatic tissue elsewhere. Infection of a nail-bed may cause enlargement of axillary glands and even an abscess. The lymphatic tissue of the stomach can behave in the same way, but there is the added factor of the digestive power of gastric juice, which will eat away any damaged tissue in the stomach and leave a hole. In the process the stomach may be perforated or blood vessels be eroded. Dr. Beaumont, in his historical description of the stomach of Alexis St. Martin, described what he saw through a gastric fistula. He sometimes saw raised red areas that were comparable to boils. Alexis was no total abstainer, nor was the popular press then in existence to direct his diet on hygienic lines. The result was that Dr. Beaumont was able to look inside the stomach of a man who frequently ill-treated it.

If the lymphatic tissue of the stomach becomes inflamed as the result of infection it is incumbent on us to discover how the infection arose, and by what path the stomach was invaded. Obviously the mouth is a possible focus of infection. The condition of the teeth and gums in many dyspeptics is beyond description, and insistence on oral hygiene may remove gastric symptoms.

The acid gastric juice has an antiseptic action on many organisms, but not on all, and it is possible for swallowed organisms to set up a gastric inflammation. Possibly also the lymphatics of the oesophagus may serve as a path for invading organisms. The following case illustrates the effect of oral sepsis.

An elderly man was treated by diathermy for cancer of the tongue. The tongue became very foul, and a large slough formed. About a week after the operation he had a large vomit of blood. There was no bleeding from the tongue, and there were no gastric symptoms in his past history. The inference was that he had an acute septic infection of his stomach. He made a good recovery.

EXTRAGASTRIC CAUSES OF HAEMORRHAGE.

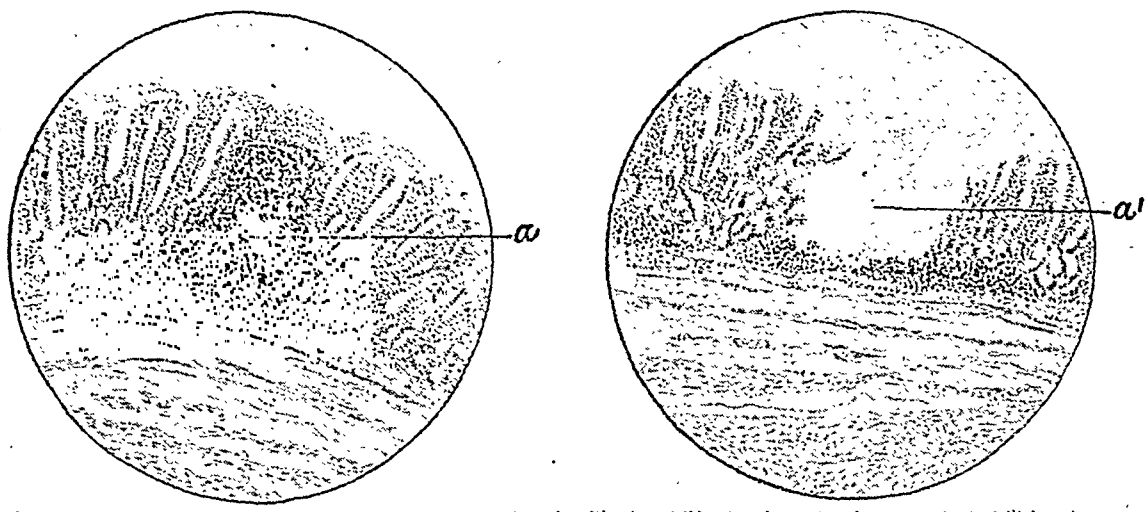
But the source of infection may be in various situations. An inflamed gall bladder may be associated with haematemesis.

A woman, aged 22, was admitted with grave anaemia, following haematemesis. After going into her history and observing her, a diagnosis of cholecystitis was made. At the subsequent operation

the gall bladder was found to contain pus and stones. Nothing was found wrong by external examination of the stomach. She was cured of her gastric symptoms and had no further haemorrhage within two years.

Perhaps the most frequent extragastric cause of gastric haemorrhage is a fibrous deformed appendix, the result of past inflammation.

A boy of 10 had to get up one night with an urgent desire to defaecate. He was found outside the privy door, unconscious, with vomited blood issuing from his mouth. He was brought to hospital, and made a good recovery, without anyone being able to discover what was the matter with him. A year later he was readmitted blanched and pulseless, and he vomited blood after admission. When he had recovered, it was found that he was very tender on rectal examination high up to the right. On his previous stay in hospital it had been impossible to examine his rectum owing to his struggles. At the operation a thick constricted fibrous appendix was removed. The stomach and duodenum were pronounced to be healthy. There had been no repetition of his trouble two years after the operation.



Other examples of similar cases could be quoted to illustrate the effect of extragastric disorders on the stomach. There are well known dyspeptic conditions that are dependent on the presence of an unhealthy gall bladder or appendix, of which examples have been quoted. But the occurrence of haemorrhage would suggest an anatomical connexion by which an inflammatory process could extend from an inflamed viscus to the stomach. Such a pathway is most readily provided by the lymphatics. An upward-going lymphatic tract can be demonstrated starting from the ileo-caecal angle and extending in the region of the pylorus. The spread of tubercles can sometimes be traced along this path, and the appearances of acute inflammation have been noticed by surgeons during life.

There may be similar lymphatic paths by which the stomach is connected to other viscera in the peritoneal cavity. It is well known that gastric symptoms are associated with disorders of other abdominal organs. When a definite organic change, such as leads to haemorrhage from the stomach, occurs in association with an inflamed appendix or gall bladder, it can be argued that there is not only a disordered function of the stomach set up by an extragastric disorder, but also a disordered structure which has been produced by an extension of the inflammatory process to the stomach. If such definite foci of infection as those of the appendix and gall bladder can be causes of gastric haemorrhage it is conceivable that such conditions as intestinal stasis with ptosis and other postural disorders can act in similar fashion. Very possibly such conditions as a "cesspool" colon can cause gastric ulceration and haemorrhage. Frequently gastric haemorrhage occurs in the subjects of enteroptosis, and in some of them chronic gastric ulcer develops.

It can be stated as a fact that a large number of cases of gastric haemorrhage are found among those whose primary trouble is outside the stomach. It is possible, and even probable, that the originating cause of a visible gastric ulcer lies outside the stomach, but this is a very difficult question which brings into consideration the degree of acidity of the gastric juice and other complicating factors. The following case is of interest and is suggestive.

A plump, constipated, dark young woman, aged 20, was admitted to hospital very pale and collapsed after haematemesis. She rallied satisfactorily, and was put through every form of examination. Nothing positive was found, except that the acid of the test meal was very high. She went out in good health, and three months later was sent for and another test meal done. On this occasion the acidity was normal and she was free from gastric symptoms. Six months later she was readmitted, blanched and pulseless, having vomited a lot of blood. She continued to vomit blood after admission. She made a good recovery and, in spite of the absence of any definite evidence, it was thought advisable to explore. A small duodenal ulcer was found. The ulcer was obviously recent and, as a matter of opinion, not older than a few weeks. Perhaps it would be safer to say that it was not a chronic ulcer.

It was thought that in this case haemorrhage had occurred as a result of an acute inflammation of the stomach, and that the small ulcers had healed, with the exception of the one found in the duodenum. One thing is certain—namely, the small ulcer found at operation was not the cause of her first haemorrhage.

Two sections from the stomach of a girl who died from haematemesis without a visible ulcer being found. *a*=lymphatic follicle; *a'*=space in the mucosa suggestive of a burst lymphatic follicle.

SUMMARY AS TO CAUSATION.

To sum up, gastric haemorrhage comes from gastric ulceration. The ulceration may be gross, or microscopic, or just visible—that is, it may be chronic or acute, and more frequently than is usually thought, it is acute and microscopic. In the majority of cases the ulceration follows infection and inflammation. Further, the origin of the trouble often lies outside the stomach.

DIAGNOSIS AND TREATMENT.

When we are faced by a patient who has recently vomited a large quantity of blood we have to treat the patient rather than the disease. It is one of the conditions in which we must treat first and diagnose later, if we can. Before we start treatment we have to consider what our aims are. We wish to improve the patient's condition, stop the haemorrhage, and prevent its recurrence. At the outset of treatment no surgical measure can be considered. First we want to ensure rest and quiet for the patient, and relief for his anxiety. The patient must be moved as little as possible; if he has to be moved to hospital, the journey should be delayed until he is well under morphine.

Morphine should be given at once, and the patient should be kept under morphine, to which atropine can be added. Perhaps after the initial dose of morphine, omnopon-scopolamine may seem advisable rather than repeated morphine. Collapse must not be too drastically treated. A certain amount of collapse is wanted so as to lower the chances of further haemorrhage. On no account

should transfusion be performed, unless a surgeon is opening the abdomen.

We have to make some sort of preliminary diagnosis. If the patient is young and well covered the condition of the stomach is probably not a chronic ulcer, and the treatment must be medical. If a history can be obtained which suggests chronic gastric or duodenal ulcer, then a surgeon should be consulted, not with a view of immediate operation, but so that he will be able to appreciate any subsequent change in the patient. If, in such a case, there is a recurrence of haemorrhage and it is thought that the haemorrhage is coming from some such vessel as the splenic vein, then transfusion of blood and exploration can take place together. But the majority of cases of gastric haemorrhage recover without the aid of the surgeon. Only in cases of repeated haemorrhage and when a chronic gastric ulcer is suspected should surgical measures be employed.

The most important question is the feeding of the patient. On this point there are various opinions. Certainly no one will object to rectal salines being given. If they are well tolerated they can be given every six hours, or the drip method can be employed. By this means thirst can be relieved. Some say that nothing, not even water, should be given by the mouth for forty-eight hours. Personally I believe this period is too long. After a haemorrhage the stomach is left in a slack state. If the blood is vomited the stomach will contract, which is a desirable state for it to be in. We cannot keep it contracted as we do the uterus after haemorrhage, but we must aim at not letting it be dilated. Dilatation is more dangerous than peristalsis. If we keep a certain amount of the digestive process going the interior of the stomach will be kept cleaner.

Further, the acidity of the gastric juice was probably too high before the haemorrhage. It may be lower after the haemorrhage, but it is probably an active juice, and it is better to give it something to digest rather than to allow it to eat its own wall. I have often given food within twenty-four hours to patients who have had haematemesis. In fact, if there has been no bleeding for twelve hours I see no reason for withholding food. The object of feeding is twofold: first, to nourish the patient so that his tissues will have a chance to heal; and secondly, to "fix" the acid gastric juice. Alkalis also should be given to neutralize the acidity of the gastric juice. While food and alkalis lower the acidity of the juice for a time, they have the faculty of stimulating a further secretion; so that treatment consists in alternately neutralizing and stimulating the secretion. This means that the patient is constantly taking something, either food or medicine.

Two names are associated with the special dietetic methods of treating gastric ulcer—Lenhartz and Sippy. As they are respectively German and American, some small modifications are desirable in their diets to make them more suitable for British tastes. But apart from these slight modifications the original diet should be closely followed. Too often one hears that the patient was treated on the lines of Lenhartz or Sippy, but without success. Failure cannot be laid at the doors of Lenhartz or Sippy, for the line of treatment will be found to have no relation to that laid down by either of them. The details of these two diets need not be given here, but the Lenhartz method is more suitable for early feeding after haemorrhage.

Drugs, in the treatment of gastric haemorrhage, have their uses in promoting rest and in lessening the activity of the gastric juice. First and most important is morphine. For peace of mind, for rest and stillness of the stomach, to allay the sensation of thirst, there is nothing to take the place of morphine. Belladonna or atropine, particularly by the mouth, lessen the secretion of gastric juice. Alkaline mixtures or powders should be given freely and regularly during treatment. The carbonates of magnesia, soda, and calcium can be used alternately with the feeds. Bismuth may be given at intervals of six hours.

Other measures have their advocates. On the analogy of the hypotonic uterus, washing out the stomach has been recommended. It is rather a trying ordeal for a collapsed patient, but possibly would do good to a patient whose stomach was distended with blood, which he was unable to vomit. However, unless a patient is dying, blood is usually vomited. Lavage then is not a method to be advised, as the passage of the tube is certain to cause tagging and straining, which will encourage further bleeding. Horse serum in various forms is recommended, but its efficacy is doubtful. Calcium has even less to recommend it. Opinions differ about opening the bowels. Some advise that no attempt be made for a week. Personally I recommend an enema or a glycerin suppository at the end of the second day, and repeating the treatment on alternate days.

After the patient has recovered from the haemorrhage full investigation has to be made into the gastric condition. In some cases there is difficulty in going further with the patient, as he may say that the haemorrhage has done him good. In some instances gastric acidity is lowered after haemorrhage, and, as many symptoms are dependent on this acidity, the patient feels better; rest in bed relieves the symptoms of many dyspeptics. But an energetic attempt should always be made to diagnose the condition which has led to gastric haemorrhage, for if the patient declines further treatment at the time he will almost certainly return at some future date on account of a recurrence of symptoms.

THE PHYSIOLOGY OF MONOTONY.

BY

R. J. S. McDOWALL, D.Sc., F.R.C.P.ED.,
PROFESSOR OF PHYSIOLOGY, KING'S COLLEGE, LONDON;
AND
H. M. WELLS, PH.D., B.Sc.

THE discussion at the Nottingham meeting of the Association on the subject of monotony was reported in the BRITISH MEDICAL JOURNAL on September 11th, 1926 (p 472). Many extremely interesting views were expressed regarding the emotions which cause monotony, but apparently no suggestion whatever was made as to how it produces its deleterious effects on the individual.

While it is true that our knowledge of the subject is as yet most imperfect, it appears desirable to put forward what information there is on the matter in order to assist in the experimental investigation of what is certainly an increasingly important industrial problem. Within recent years various workers in this department have carried out researches in relation to the integration of the circulation, and considerable evidence has accumulated which indicates that certain factors are clearly concerned.

Normally, whenever any physical effort is made the circulation at once adapts itself to the demands of the various parts of the body. During exercise a definite series of mechanisms is brought into play which causes the tissues in use to be supplied with more blood. In the first instance the metabolites of muscular activity, such as carbon dioxide and lactic acid, dilate the capillaries in the tissues being used. This has recently been made clear by the work of Hemingway and McDowall. In addition, impulses passing up the afferent nerves call into operation the Lovén reflexes by which the larger vessels to the part are also dilated. At the same time the blood supply to unused parts of the body is reduced by the increased activity of the vasomotor centre. This centre has been shown by Dale and Evans to be controlled largely by carbon dioxide, and the production of this is, we know, increased in muscular exercise. Further, as a result of compression of the valvular veins, increased respiration, and the action of carbon dioxide on the venous reservoir—both directly and indirectly through the vasomotor centre—the venous pressure is increased and the heart accelerated. The total result is that in exercise the blood pressure is markedly increased.

But the adaptation of the circulation may begin before the actual commencement of the exercise. It has long been known that the heart of a sprinter is accelerated before the race, and that the respiration may be increased. Recently evidence has been obtained by Aveling, McDowall, and Wells that the blood supply of the skin, which is not called upon until sweating commences, is appreciably

reduced. This reflex, which is brought into operation in anticipation of any effort, they purpose calling the "skin constrictor reflex." The vascular change is accompanied by a fall in the electrical resistance, and has been studied under the name of the "psychogalvanic reflex," but, as recently pointed out by McDowall and Wells, there is no doubt that the two reflexes are the same. Such a diminution of the circulation through an unused part was recorded volumetrically by Mosso many years ago, but was attributed to a passive rather than an active effort.

For our present consideration it is important to emphasize that the vascular reaction may be brought about by any form of stimulation or effort, actual or anticipated, provided the stimulus is not too often repeated.

We have definitely established that as soon as the stimulation or effort becomes monotonous the vascular reactions are no longer obtained. We have indeed found in the investigation of these problems that it might be practically impossible to get rid of the effects of psychical states after a holiday, when interest in the recommencement of experimentation itself caused a marked vascular change.

A similar condition may also be seen experimentally in animals, in which it can readily be demonstrated that the increased blood pressure which results from sensory stimulation ceases if the stimulation is often repeated, although subsequent recovery indicates that there has been no actual destruction of tissue. From the work of Sherrington it is known that in reflex arcs such conditions are brought about by an increased resistance of the synapses through which the impulses have to pass.

When a certain task is uninteresting and often repeated a similar state of affairs may result. If, in virtue of the metabolites produced and the Lovén reflexes, the active tissues still demand blood while there is inadequate closing down of the unused areas, the result must necessarily be an inadequacy of the circulation to the work done. Waste products will accumulate and a feeling of lassitude, if not actual fatigue, result. This, after all, is what we feel when we appreciate monotony. We may, then, consider monotony as the reverse of emotion, not only in the popular, but also in the physiological sense. We can, indeed, extend the well known James Lange theory of emotion, in which the experience of emotion is considered to be the sensations which arise as a result of the cardio-vascular response, to include the condition of monotony, in which the vascular response is inadequate to the needs of the body. Thus the popular saying, "The man's heart is not in his work," receives physiological corroboration.

The typical instance of such effect of monotony is the staleness of the athlete or musician. Here we may imagine that repetition of the situation no longer arouses the same interest and effort, that the circulation is inadequate to demands, and the physical best is no longer obtained. It is clear that excessive repetition, which might produce nervous if not muscular fatigue, is not itself responsible for the effect, since similar conditions of repetition of a task do not produce monotony in every person. Further, as pointed out at the discussion referred to, a potentially monotonous task, which to the individuals concerned is not so, may only become monotonous when the condition is suggested by one of themselves or a visitor.

This is exactly what would be expected according to the vascular explanation of the reflex, for the normal vascular response is itself dependent on interest, and this in turn is suggested by the conditions. Hence also it is that even a task which is apparently most monotonous will produce a normal reaction in an individual who has an interest in the task—for example, by a suggested pride in efficiency—or who performs his work mechanically, and by thinking of other things supplies the necessary interest. It is well known that certain individuals prefer monotonous tasks which permit them so to day-dream. The more rapid and efficient the sense perceptions of an individual, and the richer his associations, the more likely will he be to derive interest from any work.

While it is agreed that crude muscular fatigue is almost entirely dependent on fatigue of nerve endings, insufficient attention appears to have been given to the possibility that fatigue of much lesser degree may effect all nervous synapses, and may be dependent on an inadequacy of the circulation to the demands of the task. This is suggested by the fact that whereas Forbes and Ray have shown that the nerve fibres of mammals may survive for many days *in vitro*, and Hemingway and McDowall have shown the mammalian muscle may similarly last for several days if precautions are taken to counteract the effect of the cessation of oxidation, none of these workers have succeeded in obtaining the survival of mammalian nerve endings or spinal synapses for any appreciable period (as may be done in the frog). There is very definite evidence (Gillespie, Leonard Hill) of marked circulatory response to purely mental effort, which we find may vary appreciably according to the stimulation produced by the work, its associations and surroundings.

It should, however, be noted that it is not to be expected that the performance of a monotonous task will necessarily result in a fall of blood pressure; an inadequate rise of blood pressure would produce similar results. The subject is nevertheless clearly one which requires investigation from this point of view; but, unfortunately, the mere experimental procedure of taking the blood pressure would tend to relieve the monotony of an otherwise monotonous task. It will therefore be necessary to take vascular readings over a long period until the procedure produces no reaction whatever. The work will be continued with a view to ascertaining to what extent this is possible.

CARBON MONOXIDE POISONING:

ITS INCREASING MEDICO-LEGAL IMPORTANCE.

BY

DOUGLAS J. A. KERR, M.B., D.P.H., M.R.C.P.ED.,

ASSISTANT, DEPARTMENT OF FORENSIC MEDICINE, EDINBURGH UNIVERSITY.

ONE of the gravest social problems of the present day is the increase in suicide. This is not a new development, for unfortunately statistics for every decennium show an increase in the suicide rate in this as well as in other countries.

In 1883 Dr. Ogle, speaking on the chances of a person committing suicide, writes:

> "The total chance of dying by suicide is much more considerable than would probably be supposed by anyone who had not examined the question. Few, for instance, would imagine that one out of every 119 young men who reach the age of 20 dies ultimately by his own hand. Yet such is the case."

Last year, of all males over 20 years of age dying in England and Wales, one out of every sixty-five was a suicide.

A recent study of the statistics of suicide in a large city has brought out many interesting facts, which no doubt will be found to coincide with those of other large centres of population. Amongst these I have been impressed by the changing methods adopted by the suicide. In former years the most frequent methods in this country were hanging, drowning, and cut-throat. To-day the same methods, while still very common, no longer hold the first place, having given way to poisoning. The most frequent poison employed is carbon monoxide or coal gas, and in Scotland not only is it the most frequent poison but the most common of all methods of suicide. Indeed, the frequency of suicidal coal-gas poisoning has become a question which demands very serious consideration.

Professor Littlejohn, in a paper published in 1899, investigated the statistics of suicides in Edinburgh for the thirteen years 1883 to 1895. The total number was 298, and did not include a single case of coal-gas poisoning. The suicides in Edinburgh for the last six years (1920 to 1925) number 353, of which 105, or 30 per cent., were due to inhalation of coal gas. In some other towns of Scotland, I am informed by the Registrar-General, the percentage is even higher. If we differentiate the sexes, we find that 42 per cent. of women employ coal gas as the lethal method, as compared with 25.2 per cent. of men.

This increase in coal-gas poisoning is well brought out by the Registrar-General's reports for Scotland. The

* Read before the Medico-Legal Society, December 2nd, 1926.

figures of suicide for the years 1913 to 1925 inclusive being:

Year.	Coal Gas.	Other Means.	Total.	Year.	Coal Gas.	Other Means.	Total.
1913	10	267	277	1920	29	207	236
1914	6	255	261	1921	31	242	273
1915	8	229	237	1922	62	214	276
1916	10	210	220	1923	70	257	327
1917	13	194	207	1924	91	269	360
1918	18	172	190	1925	88	284	372
1919	18	216	234				

The total number of accidental and suicidal deaths in Scotland from coal-gas poisoning was 10 in 1913, and 108 in 1924. In England a similar increase is found, the number of suicides by this means having more than trebled in the last six years, being 213 in 1919, and 762 in 1925—a striking contrast to the number of accidental deaths, which has remained almost constant.

Death from "Irrespirable Gases" (England and Wales).

Year.	Suicide.	Accident.	Year.	Suicide.	Accident.
1918	276	149	1922	503	176
1919	213	121	1923	688	152
1920	270	156	1924	585	133
1921	365	150	1925	762	163

This large increase in cases of coal-gas poisoning gives rise to numerous medico-legal questions, of which one of the most important is that of accident, suicide, or murder.

Accidental death from carbon monoxide occurs in connexion with lime kilns, bakers' ovens, use of explosives, motor-car exhausts, and in many trades as well as from the domestic gas supply. Deaths from this latter source are by far the most frequent, and it is with these that the present paper deals. The following are typical cases of how accidental poisoning may occur.

A student, going to bed, hung his coat on the gas bracket. Owing to the weight of the coat the bracket cracked during the night. The student was found unconscious next morning, and died later in the day from gas poisoning.

A woman who lived alone lay down on a couch in the kitchen waiting for the water to boil in the kettle. She fell asleep, and was found dead with the room full of gas. It appeared that the kettle boiled over and extinguished the gas ring.

Again, where the gas has been turned off at the meter, a person opens a gas tap to light a stove, and finding the gas turned off at the main, fails to close the tap fully. The gas is turned on later at the meter, with fatal results. The same type of accident may also occur with the penny-in-the-slot meter.

It is by no means infrequent to see reports in the press of deaths from coal gas in houses in which there are no gas pipes, the gas from a cracked main under a tar-bound or frozen road having found an outlet through the soft ground in the basement of the house. Accident can only be excluded by the circumstances, and in some cases the answer cannot be determined. In Edinburgh during the last six years there have been only seven unquestionable cases of accident.

Suicide is very frequent, and, as a rule, circumstances exclude accident. The victims in the great majority of cases are found with their heads covered with coats or blankets, and with the tube from a gas tap brought under the edge of the covering article. In several instances persons have been found sitting in a chair with the gas tube close to or in the mouth, and still held in position by the hand; or they have been found lying on the floor with the head in a gas oven. In one case a woman was found with a mask which she had made out of a tea cosy tied over her face, the gas tube having been introduced through a hole in the top of the cosy.

It is well to remember, however, that these conditions may be simulated by a murderer. The question of possible homicide is one of great importance, and six cases were reported under this heading in the Registrar-General's (England) returns for 1925.

What is to prevent a murderer turning on the gas when his victim is asleep? When unconsciousness has developed he may lead a tube from the gas to the victim's mouth and place a covering over the head, or make some other arrangement such as is described only too frequently in the newspapers. In this connexion a case which occurred this year is of interest.

A labourer employed in working down a well was found dead in bed. As in the case of all sudden deaths in Scotland, the matter was reported to the police for investigation. Professor Littlejohn, who examined the deceased on their behalf, was struck with the very pink colour of the *post-mortem* lividity. The Procurator Fiscal was informed, and ordered a *post-mortem* examination in view of a probable fatal accident inquiry being held. The examination showed that death was due to carbon monoxide poisoning. The man's wife stated that he had complained of a smell of gas in the well, and that his clothes smelt strongly of gas when he returned from work. On further investigation it was found that the man left his work at mid-day on Saturday, returned home for his dinner, and was seen walking about the town in the afternoon and evening. The family heard him return home about midnight, and move about the kitchen, where he slept alone. The kitchen contained a coal fire and also a gas ring, and he had apparently cooked himself some supper as was his usual custom. Next morning at 7 o'clock his wife entered the kitchen to prepare breakfast, but stated that she noticed no smell of gas, nor did she find the gas tap turned on. Thinking the deceased was asleep, she left him until 11 o'clock, when, on trying to wake him, she found that he was dead.

The question arose, Was this a case of accidental death from exposure to coal gas at his work; was it suicide, or a case of homicide; or, as we shall consider in a moment, was this a case not of coal-gas poisoning, but of *post-mortem* development of nitroxyhaemoglobin to which Haldane has drawn attention.[1]

An estimation of the percentage saturation of the blood was made by Hartridge's reversion spectroscope, which excluded the last-named possibility. The saturation was found to be over 70 per cent. We know that in cases of poisoning by carbon monoxide where the person is unconscious, the carbon monoxide is eliminated from the blood when the patient breathes fresh air, and after five or six hours only an infinitesimal amount is present; this man, therefore, who was seen and heard going about twelve hours after leaving his work, and who never complained of breathlessness or other symptoms, could not have contracted a saturation of 70 per cent. from the well, as this would have been eliminated many hours before, not to speak of the fact that a much lower saturation than 70 per cent. causes unconsciousness. We are therefore forced to the conclusion that the man became unconscious in the atmosphere that contained the carbon monoxide which poisoned him. There can be no doubt that he was gassed in the dwelling-house.

Whether this was a case of homicide or, as would appear more probable, one of suicide, is a matter of conjecture, since police and other inquiries could not get evidence to enable any criminal charge to be made. I believe a claim for compensation was made by the family and settled out of court, the employers preferring this to having any suspicion raised that their well was contaminated with coal gas.

This case illustrates most of the medico-legal questions arising from carbon monoxide poisoning—namely, (1) the possibility of mistaken diagnosis; (2) the toxicity and amount of saturation of the blood required to produce unconsciousness; (3) the time elapsing before a person becomes unconscious; (4) the rate of elimination.

With regard to the first of these questions, as to the possibility of any other condition being confused with carbon monoxide poisoning, Haldane reported a case in 1925 where the verdict at the inquest was given as "carbon monoxide poisoning contracted during employment." This when investigated proved to be due to a condition which had developed after death—namely, the formation of nitroxyhaemoglobin, a substance which gives the *post-mortem* appearances seen in carbon monoxide poisoning, and which gives similar reactions with the usual

tests, such as a pink colour on dilution, Kunkel's tannic acid test, and the spectroscopic test. Carbon monoxide poisoning and nitroxyhaemoglobin can, however, be distinguished by boiling a dilute solution of the blood, or by means of an instrument devised by Hartridge, known as the reversion spectroscope, which is used as one of the methods for estimating the percentage saturation of the blood with carbon monoxide.

This *post-mortem* condition of nitroxyhaemoglobin is rare, and the circumstances are sufficient to exclude it in most cases. In a very small percentage of instances, however, such as the case of the labourer working in the well referred to above, the possibility may arise, and in such circumstances care must be taken to exclude it.

Carbon monoxide gas unites with the blood much more readily than does the oxygen of the air, and causes death, not by any toxic action, but by depriving the tissues of the oxygen which it has displaced. Sometimes the patient survives for several days, and samples of the blood after a short time show no evidence of the presence of carbon monoxide. Death in such cases results from cerebral softening—an after-effect of the acute anoxaemia.

The symptoms caused by a given percentage saturation of the blood vary with the individual and the rapidity with which the saturation has been produced. Distinct symptoms of weakness and malaise are present with a saturation of 50 per cent.; between 50 and 55 per cent. any exertion such as walking is difficult, and above this unconsciousness is produced. When the accumulation in the blood is rapid, such as occurs when air containing a large amount of carbon monoxide is breathed, the saturation required to produce the above symptoms will be less.

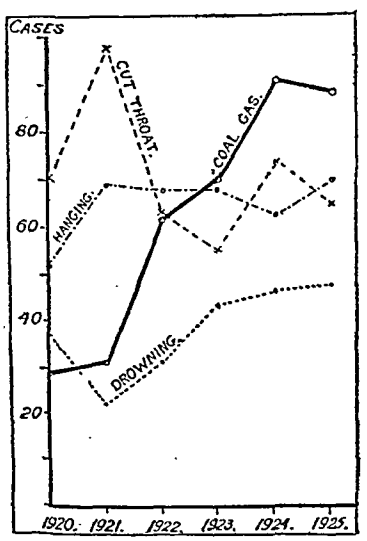


FIG. 1.—Chief causes of suicide, Scotland.

The rapidity with which carbon monoxide accumulates in the blood varies with the amount of the gas present in the air. An individual breathing an atmosphere containing 1 per cent. of carbon monoxide will have 50 per cent. of carbon monoxide in his blood in fifteen or sixteen minutes. Exposure for twenty minutes is thus approximately the time required for unconsciousness to develop with this percentage in the air. If a person puts his head in a gas oven he will be breathing almost pure coal gas, which in Edinburgh contains at present 22 per cent. of carbon monoxide. Under such conditions unconsciousness will theoretically occur in about thirty seconds.

The rate of elimination of the gas after the patient has been removed from the atmosphere of carbon monoxide is also of importance from the medico-legal standpoint. Henderson[2] has shown that for the first hour and a half the elimination is small, but after that becomes rapid, and, provided the patient lives, all the carbon monoxide should have been eliminated in from five to six hours.

In the case quoted by Haldane, to which reference has been made, the verdict of carbon monoxide poisoning at the inquest was founded on the bright pink colour of the blood seen at the *post-mortem* examination, and on the positive results obtained from the usual tests for carbon monoxide. Fourteen days had, however, elapsed before death occurred, so that in this case it is evident that the appearances and positive tests could not have been due to carbon monoxide gas. Had the above facts connected with gas poisoning been more widely known this mistake could not have occurred.

The increasing frequency and the various medico-legal problems associated with carbon monoxide poisoning have been briefly considered; it is now necessary to discuss whether anything can be done to limit its occurrence.

The poisonous element in coal gas is the carbon monoxide, most of which is added in the form of water gas for the purpose of increasing its heating properties. Yandell Henderson,[3] in an article on poisonous gases, stated:

> "It is well established that the number of deaths each year in any city due to its illuminating gas rises in direct proportion, or even in more than direct proportion, to the amount of carbon monoxide in the gas. In those cities where coal gas of low carbon monoxide content is supplied asphyxiations are few. In New York City at the other end of the scale, where the gas contains nearly 30 per cent. of carbon monoxide, the number of deaths from carbon monoxide asphyxiation runs up toward 500 a year."

In this country Dr. Stevenson, representing the Registrar-General's department, giving evidence before the Departmental Committee on Carbon Monoxide Poisoning in 1921, stated that "The death rate from accidental coal-gas poisoning for towns where water gas was added to the gas was two and a half times higher than for towns in which none was supplied." It is evident that the percentage of carbon monoxide in the gas affects the death rate from coal-gas poisoning.

In the last five years there have been two Government inquiries into deaths from coal gas—one in 1921, the other in 1924. Both these inquiries have, however, been limited to accidental deaths, the increase of which, they state, has only been slightly above the proportional increase in the number of premises supplied with gas.

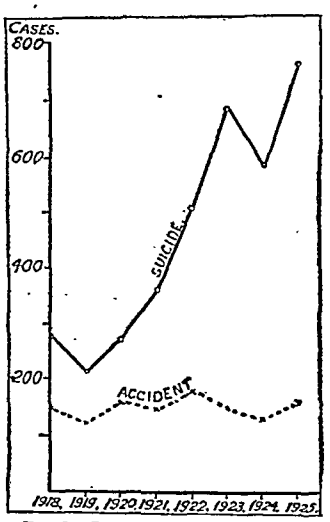

FIG. 2.—Coal-gas fatalities, England and Wales.

The 1924 committee reported that the question had been considered solely from the standpoint of the risk of accidental poisoning, and concluded that a limitation in the proportion of carbon monoxide in lighting gas would cause very little reduction in the number of accidental deaths, and would gravely disturb the economic factors which govern the price of gas, the reason for this opinion being apparently because the majority of accidental deaths occur in bedrooms during the night, and the victims are subjected to prolonged exposure. From the accidental point of view any alteration in the composition of the gas supplied does not appear to be a practical proposition, and, in any case, the rise in the number of accidental deaths is not very great.

In February of this year the Parliamentary Secretary of the Board of Trade referred to the 1924 report, in answer to a question in Parliament as to whether he would cause inquiry to be made into the deaths from carbon monoxide poisoning. He stated that the position was being watched, and that during 1925, in the area supplied by the three London gas companies, there were twenty-seven such deaths in which either an open verdict or a verdict of accidental death was returned. This is not an alarming number. We have, however, to add to this 153 suicidal deaths of which no mention was made.

It is to the prevention of suicidal poisoning that I desire more particularly to direct attention. It may be said that if one method is removed a suicide will find another. That this may be so is beyond dispute, but there are many cases in which suicide would not be attempted if some difficulty was placed in the way of employing a particular method. The temptation of an easy means at hand is often the deciding factor. As an instance of this, suicides were very

frequent some years ago from a well known bridge in Edinburgh which had a low parapet and might almost be said to invite suicide. The parapet was raised and crowned with sharp spikes, with the result that no suicide has occurred there since.

We have seen that carbon monoxide is a cumulative poison, and that fatal results will occur with even small amounts in the atmosphere provided the exposure continues for some time. Would a reduction in the amount of carbon monoxide in lighting gas, and thus a prolongation of the time necessary to produce a fatal result, be of any use? In a number of cases it would result in the person being found before it was too late. This is shown by the fact that of eighty-two admissions to the Royal Infirmary, Edinburgh, of lighting-gas poisoning in the last six years only six have died. On the other hand, a suicide frequently tries to make certain of a speedy result by covering his head with blankets, or putting his head inside the gas oven, etc., and so artificially raises the concentration in the atmosphere he breathes. In such circumstances, it must be admitted, reduction in the carbon monoxide content would not have much effect.

The question of limiting the amount of gas supplied by means of a penny-in-the-slot meter is likewise of little advantage, as I have seen fatal results in cases where such meters were in use. Approximately 25 cubic feet of gas are obtained for a penny, which, if it contained 20 per cent. carbon monoxide, would give 5 cubic feet of carbon monoxide—a quickly fatal concentration in an ordinary sized bedroom.

It seems a pity that the question of suicide should have been eliminated from the Government inquiries, especially in view of the statements of Yandell Henderson and Dr. Stevenson, and of the rapid increase in suicidal cases.

In considering the question of the limitation of suicide we must not confine ourselves to a discussion of the composition of gas, but must consider any other methods which are applicable. There is no doubt that a large number of cases of suicidal gas poisoning are due to the publicity given to this matter by newspapers. As I mentioned before, suicides are easily influenced by example and suggestion. A suicide occurs by some unusual means which is reported in the press, and is quickly followed by another in which the same means are employed. An example of this occurred recently in Edinburgh, where two men cut their throats, and then jumped from a viaduct into a river below, within a few days of each other.

Not infrequently the relatives state that the deceased had remarked on similar suicides which he had read about in newspapers. There can be no question that the publication of details and reports of inquests in cases of suicide does a great deal of harm. A few months ago these cases were broadcasted in the evening news bulletins, but fortunately the B.B.C. eliminated such items when their attention was directed to the grave results of such publicity.

Legislation has recently been proposed to suppress the publication of certain classes of divorce court proceedings. It is surely of greater importance to suppress reports of suicides, which constantly remind unfortunate individuals of the ease and certainty of death as a way out of their troubles. Whether the suppression of publication of suicides would have any beneficial effect on the number of cases of coal-gas poisoning cannot, of course, be definitely asserted, but that absence of such details would be an advantage to the community cannot well be doubted.

BILHARZIA OVA AND THE TEST TUBE.

BY

J. B. CHRISTOPHERSON, C.B.E., M.D., F.R.C.P.,

PHYSICIAN FOR TROPICAL DISEASES, FREEMASONS' HOSPITAL; PHYSICIAN TO OUT-PATIENTS, CITY OF LONDON HOSPITAL, VICTORIA PARK; LATE SUDAN MEDICAL SERVICE.

THE statement that antimony tartrate kills the ova deposited in the tissues during treatment for bilharzia disease has been assailed by Dr. Mohamed Khalil,[1] who states that the action of tartar emetic in curing bilharziasis is not due to its effects on the eggs, and that miracidia are not affected by tartar emetic in the dilution approximating to that used during treatment. Lately, Captain W. H. Dye[2] has said more specifically: "I cannot agree that the ova are killed by tartar emetic." In view of the fact that there is general agreement that antimony, both *in vitro* and *in vivo*, kills the parasite[3] which produces the ova—a fact contested for some time—the question of the effect of antimony on the ova might appear of no great importance; it is, however, important, for if the ova are *not* killed, they will leave the bladder or rectum and continue to infect the intermediate hosts, and the drug is not so great a prophylactic agent as is claimed; further, if antimony has no therapeutic effect on the ova we lose a reliable method of observing the results of the action of antimony during a course of treatment.

Certain facts with regard to the ova during the administration of antimony tartrate can be made out by anyone who has a microscope and a patient with bilharzia disease. They occur in rectal and in vesical infections; they are obviously more easily observed in the urine than in the faeces. A specimen of the urine of a moderately severe case of bilharzia disease is cloudy and contains blood—macroscopic or microscopic; if it be allowed to stand for half an hour in a conical glass the sediment at the bottom will be found to contain ova, most of which are more or less transparent, showing the miracidium usually with the anterior end at the extremity which is not spined. The outlines of primitive embryonic organs will be easily seen within the miracidia; these are live ova and comprise by far the greater portion.

There are a few which appear shrunken with double contour replaced by a single bounding membrane. The contents of such ova are granular, without shape or form, dead; some are calcified. If the urine containing the ova be diluted and the temperature of the solution raised to 110° or 120° F., most, but not all, of the living ova will hatch out within half an hour; none of the granular-looking ova will hatch. If fresh specimens of urine are examined day by day the same facts will be noticed with little change, the number of the ova varying, but always there will be dead and living, the living outnumbering the dead.

Now commence treating the same person with intravenous injections of antimony tartrate. After a few days the urine will clear perceptibly, the blood will diminish, and blood obvious before to the naked eye is now obvious only under the microscope. It will be noticed that the number of ova in the urine has sensibly diminished. A decisive action has taken place, which has affected the number of ova and has diminished the blood in the urine.

These facts can only be logically explained by assuming either that the antimony is acting on the ova, or that its action on the female worms causes them to lay fewer eggs.* Continuing the injections every other day, the improvement is maintained, the local symptoms are relieved, and there is less pain, less frequency, and less difficulty in micturition.

Still continuing the injections, the initial dose of half a grain is increased by half a grain each succeeding dose according to rule, to the maximum dose of 2 or 2½ grains, which is then continued. On the eighth or ninth day of regular treatment a definite and increasing change in the character of the ova can be observed. Many containing well formed miracidia hatch slowly or not at all on the addition of water, while increasing numbers of ova show granular and degenerated miracidia. In fact, from the

* Recently Fairley has revived the theory that the action is a specific one on the female worm (he admits a definite action on the ova). It is difficult to understand why the antimony should affect female rather than male parasites as Fairley suggests, or why, acting on the female, the latter should continue to lay dead or addled eggs. One can understand the female being affected by the antimony and laying no eggs at all. This Christopherson has suggested as a reason why ova are scanty during treatment.

ninth day onwards ova appear in the urine, which, owing to the action of the antimony tartrate, have become granular and black. By the end of a fortnight's treatment about half the ova discharged are obviously dead; many are quite opaque.

On about the twentieth day of treatment all the ova coming away will be dead; none will now hatch out on diluting and warming the urine, and if the adult worms are killed, as is probable, live ova will not reappear in the urine. The injections commenced early to affect the ova. The first action of the antimony *in vivo* is observed by testing the physiological function of hatching; as more injections are given the ova are increasingly affected and fewer living ova are found; lastly, the parent worms are killed and living ova no longer appear in any circumstances but reinfection. I think it is impossible to maintain that this sterilization change in the ova is not the direct result of the antimony injections. Other drugs also kill the ova, but no drug deals with bilharziasis so completely as antimony tartrate, because none have so great parasitotropic action and so little organotropic in comparison.*

These are changes which must be observed *in vivo* with the parasites in their natural media; they cannot be adequately studied in the test tube, nor can test-tube observations, however accurate and in many respects valuable, take the place of clinical experience. In support of this, if support be needed, we might contrast Dale and Dobell's[4] experience with *Entamœba histolytica* and emetine *in vitro* with the clinical results obtained with the same drug.

H. B. Day[5] investigated a series of 1,000 cases at the Kasr el Aini Hospital, Cairo, and published carefully drawn charts to show the effect of antimony on the ova. He found that the ova of bilharzia *in vivo* are very susceptible to antimony; a short course of four injections will kill them, the effect being seen after about nine days, and it is the same when the doses are continued; it is evident that it is the small dose acting over a prolonged period which kills when antimony is given in clinical practice. When only small doses are given for two or three days dead ova appear after the ninth day, and the effect reaches its maximum on the fifteenth day, after which living ova become more and more numerous Thus a very little antimony given kills the ova, but the worms revive and recommence laying. We have actual proof that antimony in a short course does not kill the worms till later, since Day found living worms at a *post-mortem* examination of a patient who died of an intercurrent disease after a short course.

It has been said by way of objection that granular ova occur in bilharzia cases not undergoing treatment. This is true, but the sudden diminution in the number of living ova coming through after a few days of antimony administration, and the cessation of pain and blood, and the clearing of the urine can only be explained satisfactorily by supposing that antimony has already attacked the ova and paralysed them, or that the worm is under the influence of the drug and therefore is not laying. The ova no longer penetrating the mucous membranes of the bladder in such numbers there is less cause for haemorrhage, and the urine becomes more acid and natural in appearance.

Further, if the dead ova in a case undergoing treatment are counted and the number compared with the number of live ova, it will be found to be out of proportion to the number of dead ova coming through in a case not receiving treatment. This points to the fact that it is the ova which are killed by the antimony. These shrivelled ova whose double contour is replaced by a single outline, the miracidia within replaced by a shapeless granular mass, always opaque, generally appearing black by transmitted light, are not capable of hatching in any circumstances. The foregoing facts may be verified by anyone with a patient and a microscope.

* One could understand a parasite laying one dead egg or two, which would correspond to abortion in a human being, but is it a biological fact that tartar emetic makes the parasite continue to lay dead ova? In other words, is not the action of the tartar emetic a direct one on the ova as they lie in the tissues?

Both Day and I, however, obtained in addition results with watery solutions of tartar emetic which showed that there was a distinct, though retarded, action by the antimony on the ova *in vitro*. In order to imitate natural conditions more closely the former also experimented with saline solutions. Day pointed out that work *in vitro* has its limitations. A time limit is imposed, since the ova are not in natural surroundings; they are, in fact, in contact with infected liquids, the ova being recovered from urine which is more or less contaminated with bacteria, whilst when living in the tissues they are bathed in serum—a benign medium from which the ovum derives its nutrition. By using serum for the medium the results of experiments on the ova *in vitro* might possibly have been still more striking.*

I submit, therefore, that *in vitro* experiments also prove the direct toxic effect of antimony on the ova. They further suggest that the phenomenon of hatching of the bilharzia ova is a vital process, not governed exclusively by physical laws, for whereas antimony appears to have a profound effect on the live ovum, it apparently has no effect on the dead ovum.

The action of antimony on the living ova is real, an early manifestation, and only second in importance to the action of the antimony on the adult worms, which it kills later. The action on the ova and on the adult parasite makes antimony the most valuable therapeutic agent we have in bilharziasis, and probably one of the most complete remedies in our therapeutic armoury.[10]
